This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world’s books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that’s often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book’s long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ **Make non-commercial use of the files** We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ **Refrain from automated querying** Do not send automated queries of any sort to Google’s system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ **Maintain attribution** The Google “watermark” you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ **Keep it legal** Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can’t offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book’s appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google’s mission is to organize the world’s information and to make it universally accessible and useful. Google Book Search helps readers discover the world’s books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at [http://books.google.com/](http://books.google.com/).

ABATIMENT OF LEGACIES. [LEGACY, P. C., p. 391.]

ABATI, or ABATTI, NICCOLO', was born at Modena in 1512. He is more frequently called Dell' Abate, but erroneously according to some foreigners, as his family name was Abati. Before Tiraboschi, Niccolò's surname was supposed to be unknown, and the name of Dell' Abate was given to him from the circumstance of his being less known for his own works than as the assistant of Primaticcio, who was called L'Abate by the Italians after he was made Abbé of St. Martin near Troyes, by Francis I. of France.

Abati executed in fresco the Adventures of Ulysses and other works from the designs of Primaticcio, for the palace of Fontainebleau, the decoration of which was intrusted to Primaticcio after the death of I Rosso. Prints from the Adventures of Ulysses, by Van Thulden, were published in Paris in 1630: the original works were destroyed by the building, in 1798, to make room for a new structure.

Abati's own works, however, in Modena and Bologna, were productions of the greatest merit, according to the Caracci; and in the celebrated sonnet of Agostino, which is a sort of recipe for making a great painter, he is mentioned in conclusion as combining in himself all the required excellences:—

Ma senza tant'arte e tanto stento Si ponga ad il core a fumare Che qui la fonto il nostro Niccolino.'

There are few of Abati's works remaining, and these are chiefly frescoes; he seems to have painted comparatively little in oil. It is not known who his master was, or whether he had any other master than his father Giovanni Abati, who was an obscure painter and modeller of Modena. From a similarity in his works to the style of Correggio, some have supposed that he was a pupil of Correggio; he is also said to have studied under the sculptor Begarelli: if so, he was probably well acquainted with Correggio, with whom Begarelli was intimate.

His earliest essays upon his own account were in partnership with another painter, Alberto Fontana, a practice not unusual at that period in Italy, when there was little or no distinction between artists and artisans in the manner of employing them or estimating their works. In 1537 he painted with Fontana, at Modena, some frescoes in the butchers' market, by which he obtained some reputation; and he acquired great distinction when he decorated the Scala dei Giganti, in the palace of the Grand Duke of Tuscany, which is still extant; they have been engraved by Gajani. These, with some conversation-pieces and concerts in the Institute of Bologna, a Nativity of Mary, and the portico of the Leoni Palace, and a large symbolic picture in the Via di San Mamolo, in the same city, are the only frescoes now extant by Abati; and his oil-pictures are likewise very scarce.

P. C. S., No. 1.

Of the works in the Institute Zonetti has written an account—Delle Pitture di Pellegrino Tibaldi e Niccolo Abati,' &c., in which there are engravings of them: Malvasia also has given a laudatory description of them: they have been compared with Titian. The Nativity of the Leoni Palace, which has been engraved by Gondolfi, is mentioned in the highest terms by Count Algarotti, who discovered in it 'the symmetry of Raphael, the nature of Titian, and the grace of Parmegiano.' Of his easel-pictures in oil, the most celebrated is the Martyrdom of St. Peter and St. Paul, a large picture on wood, which was painted for the Church of the Benedectines at Modena, in 1648. It is now in the Dresden Gallery, and has been engraved by Folkema for the 'Recueil d'Estampes après les plus célèbres Tableaux de la Galerie de Dresde.'

From about 1646 until 1659, when he accompanied Primaticcio to France, Abati lived in Bologna, and his Bolognese works were painted during this interval: he died in Paris, in 1571.

Abati's principal faculty was painting in fresco, in which he had surprising facility. According to Vasari he never touched his works when dry, which cannot be said of many fresco-painters: yet, says Vasari, the paintings of an entire apartment were executed with such uniformity that they appeared to be the work of a single day. Abati excelled in landscape, for his period: there is a Rape of Proserpine in the Duke of Sutherland's collection, of which the background is an extensive landscape; it was formerly in the Orleans Gallery, and was sold at the sale in this country in 1860.

Several of Abati's relations also distinguished themselves as painters: his brother Pietro Paolo was a clever horse and battle painter; his son Giulio Camillo, his grandson Ercole, and his great-grandson Pietro Paolo the younger, were all painters of ability, especially Ercole, who was born in Modena in 1653, and died in 1618; he executed, with B. Schidone, the frescoes of the council-ball of Modena.

(Vodiani, Vite de' Pittori di Modena; Tiraboschi, Notizie de' Pittori, &c. di Modena.)

ABERCROMBIE, JOHN, M.D. Fellow of the Royal Colleges of Physicians and Surgeons of Edinburgh, &c., was born on the 11th of November, 1781. He was the son of the Rev. Mr. Abercrombie, for many years one of the town-ministers of Aberdeen. Edinburgh was at the time the most distinguished seat of medical education in the empire. Applying his mind to that branch of professional knowledge, Abercrombie studied in the Scottish metropolis, and took his degree there on the 4th of June, 1803. He entered into practice subsequently in Edinburgh, and became a Fellow of the Royal College of Surgeons in that city in 1805, thus qualifying himself to teach surgery, and taking the highest professional rank in that class.

However, though he so far combined the practice of a surgeon with that of a physician even in his early career, according
to a common Scottish custom, his disposition was better suited to the pursuits of the pure physician; and into these he fell altogether soon after the decease of the celebrated Dr. Greg-
ory in 1821. Dr. Abercrombie from that time began to oc-
cupy the entire time and attention of a man elected con-
ducting physician, not only in Edinburgh but in all Scotland, and
he was often called to great distances in the country. He
became a licentiate of the Royal College of Physicians in 1823,
and afterwards received a Fellow of the Royal Society. With
receiving subsequent honours from his colleagues, his high
position in after-life also gained him many complimentary
distinctions from other quarters. In 1834 the University of
Oxford marked their estimation of his character and talents by
confering upon him the honorary degree of Doctor of Medi-
cine—a somewhat rare mark of respect to the alumni of
Scottish universities. In the year 1856 Dr. Abercrombie was
elected Lord Rector of the venerable Marischal College of
Aberdeen. Of the other honours bestowed upon him by public
and private bodies, we need only notice his appointment to the
vice-presidency of the Royal Society of Edinburgh, and to
the office of physician in ordinary to her Majesty for Scot-
land. The numerous subsidiary places which he held, most of
which were connected with benevolent societies, need not be
enumerated. Dr. John Abercrombie died suddenly on Thurs-
day, November 14, 1844, at his house in York Place. On a
post-mortem examination, it was found that the bursting of
the coronary artery of the heart had been the immediate cause of
death.

The writings of Dr. Abercrombie contributed no less to the
establishment and maintenance of his fame than his singularly
useful career as a practical member of his profession. In the
earliest months of his professional career he published:
*Edinburgh Medical and Surgical Journal,* and other peri-
odicals in his own department of science. His first distinct
work of moment, leaving out of consideration published cases
of disease and similar minor treatises, was one entitled
*Pathological and Practical Researches on Diseases of the
Brain and the Spinal Cord,* Edinburgh, 1828, 8vo. In this
work, which is characterised by no ordinary degree of purely
scientific knowledge, he also gave an indication of the beauty
of his mind. He had been long accustomed to discuss the
cases of mental disease, and had thus acquired a high
degree of extensive experience and reading, and to examine their
bearings on the various metaphysical and moral systems that
have been established. The result of his labours is to be found
in the three volumes which were published under the titles:
*Imaginative and Intellectual Powers and the Investigation of Truth,*
Edinburgh, 1830, 8vo; and the other called *The Philosophy of the
Moral Feelings,* London, 1833, 8vo. The latter is in some
measure sequel to the first, and the whole compendium view
of human nature intellectually and morally, in which the facts
of science and the revelations of religion are combined together
in peculiar harmony. The best of these two works in every
respect is perhaps that on the Intellectual Powers. It is not
so much the product of profound original research, as the na-
rnal result of the quiet meditations of a superior mind aided by all
the advantages of much reading and large practical experience.
The work is more reflective than penetrative or suggestive.
In both, we find the labour of the author on whose critical
cases of spectral illusions which have so long interested the
medical profession, is a proof at once of Dr. Abercrombie's
powers and skill in his profession, and of his capacity for in-
vestigating the difficulties of mental philosophy. In so brief
and so elaborate a treatment, he manages to show the mind con-
tained in a man as Dr. Abercrombie. For range of acquisitions, sol-

tude, he stood unexceeded among the Scottish physicians of
his day. He earned by his writings a name that will not be
lost, but be preserved as the mark of a genius, not of a private
individual, for his singular pieté and benevolence.

**ABERDEENSHIRE,** a maritime county in the east of
Scotland, bounded on the north-east and east by the North
Sea, on the south-east by Kincardineshire, on the south by
Forfarshire, and on the west by Inverness-shire, and on the
north-west by Banffshire. Its form is irregular, having its greatest
length from east-north-east to

d-west-south-west, from Rattray Head between Peterhead and
Fraserburgh to the junction of the three counties of Perth,
Inverness, and Aberdeen, 88 or 89 miles; and its greatest
breadth at right angles to the length, from the border of the
county of Banff to the city of Aberdeen, 34 or 35 miles. A
small part of Banffshire (the parish of St. Fergus) is insularised
by this county and by the sea near Peter-

head. The area of Aberdeen, including the few lochs,

which are stated to be large, is 1,892,000 acres. While

inhabitants are described as 1,169,000, the

estimates make it rather less); it is in size the fifth of the
Scottish counties, being 658 square miles less than Perthshire,
the next county above it, and 163 miles greater than Suth-

erlandshire, the next below it. The population at the different
quarters of the county is stated as follows:—

*1801, 150,683; 1811, 153,075; increase in ten years 10 per cent; 1821,
153,387, increase 15 per cent; 1831, 177,657, increase 14 per cent; 1841, 192,283, increase 8 2 per cent. In the

years from 1811 to 1831 the rate of increase exceeded the average of Scotland; but during the rest of
the period it has been below the average. According to the
census of 1831, which we retain to facilitate comparison, there
were 90 persons to a square mile. It was then the third of the
Scottish counties in amount of population, being exceeded only
by Lanarkshire and Edinburghshire; and the thirteenth in
density of population, being next below Kinross-shire and next
above Elginshire. According to the census of 1841 it retains
its rank in the same order. The number of inhab-

itants in the county was 977,956, while the

area in the form of that county is 1,892,000 acres; the

annexation of Banffshire, which was an

accretion of 19,423 acres, the county then

became of 1,892,119 acres. The area of.the

county is within the limits of its ancient

custom, but the sea has eaten the dimoun of

about 5,000 acres, and the inincrease of popula-

tion: it had then between 93 and 98 inhabitants to a square mile.

**Coast-line.—** The coast of Aberdeenshire has a tolerably
regular outline, for the most part convex to the sea. From
Edinburgh, on the north, to the mouth of the Dee, it is 100
miles; from Edinburgh to the mouth of the Forth, it is 102
miles; from Edinburgh to the mouth of the Firth of For-

cardineshie, it proceeds in a tolerably direct line for 12 miles

north by east or north-north-east to the mouth of the Ythan.
The Don and several smaller streams fall into the sea in this

part of the coast: the mouth of the Dees, about 2 miles

north of the mouth of the Dee; the outfall of the other streams

is more to the northward. From the Ythan the coast at first

runs a little more to the eastward, but turns gradually to the

north, north-west, and west, forming near Broughty Ferry a

little promontory, divided from the mouth of the little stream

which separates the county from Banffshire. In this semi-

circular sweep the coast has several headlands, but little promi-

nence: they are White-ness, Brigges-head, Bows-ness, Boddam

or Buchan-ness, Invernessy-point or Salloth-head, Inchkeith-

point (the last three in Peterhead parish, and near the town

of that name), Rattery or Rattray-head, Tillyduff-point,

Calmhulg-point (all three between Peterhead and Fraser-

burgh), and Kinnaird-head near the county of Banffshire.
The most landward point is in the detached part of Banffshire,

between Inchkeith-point and Rattray-head. Buchan-ness and

Inchkeith-point are the easternmost points of the mainland of

Scotland: they are in 1° 45' W. long. There is a light-

house 118 feet high, which is painted in white and black, and

presents the form of a lighthouse, being stilted at its top by

a flashing light, on Buchan-ness. The bays between the mouth

of the Ythan and the point where the boundary between this

county and Banffshire meets the coast, are—Cruden bay,

between Briggs and Buchan-ness; Bows-bay, between

Banffshire and Boddam-ness; between Cruden bay, Buchan-

ness and Salloth-head; Peterhead bay, between Boddam-

ness and Inchkeith-point; St. Fergus bay between Scoto-

stown-point (in the detached part of Banffshire) and Rattray-

head; Strathbeg or Stratheg bay, and Rattray bay (which at

low water becomes a lough, communicating with the open

sea by a narrow passage adjacent to Rattray-head on the north-

west); Fraserburgh bay, between Calmhulg-point and Kinnaird-

head, Fingask bay, west of Kinnaird's-head; and Aberdour

bay, near the Banffshire boundary.

The coast from the border of Kincardineshire northward
to the mouth of the Ythan is comparatively low and shelv-

ing: from the mouth of the Ythan it assumes a bolder

character, being scarred in some places by great promontories

of 200 feet above the level of the sea. These rocks are gen-

erated by some remarkable fissures and caverns which formerly

afforded great facilities for the concealment of smuggled

goods. The rocks are chiefly of black slate rocks, mica slate

granite. About Peterhead they form mural precipices. Some

of the bays which indent this generally bold coast have a flat

beach of sand or pebbles. North of the Ugie, which joins the

sea just to the north of Peterhead, the shore loses its arid

character, and the Ythan and little stream which separates

an accumulation of drift sand; near Rattray-head there is a

ridge of rocks projecting into the sea, by which at high

water they are covered. Beyond Brairay-head the coast is low and sandy to Kinaird's-head, a promontory of considerable
height: westward of which the coast is sometimes sandy,
sometimes lined with rocks, in which are some remarkable
caves. Great Traps, a group of the most remarkable, are found in the peninsula of Bressay, a high island to Lord
Pitlurg after the battle of Culloden in 1746. There are no
islands on the coast deserving of notice.

Surface and Geology.—The county is generally hilly; in
the south-western part it is mountainous. The crest of the
principal chain of hills is found in the eastern part of the
county, but there are many other similar systems of low
hills and hilly parts of the county; and veins or dykes of trap
are observed in parishes near the east coast. (Boi., Essai Geo-
logique sur l'Écosse; New Statistical Account of Scotland.)

The mountain district of Braemar, in which the neigh-
borhood most of these peaks are included, is chiefly granite:
the mountains frequently present conical summits with steep
precipitous sides. Ben Macdhui has on its sides precipices
of more than 1000 feet high. Conical summits are not so frequent,
but Cairn Toul and Loch na Gair have this form. The sides
of the mountains vary in character, presenting sometimes mural
precipices, sometimes slopes more or less steep: at the foot of the
precipices or steeper slopes considerable masses of granite
defbris are observable. The granite of Braemar is chiefly pure;
the mica is the least of its constituent minerals: the felspar and
quartz, in the proportions of 70 to 30, make up the bulk of the
granite, and the mica is porphyritic. In the upper part of the
valley of the Dee a large mass of syenite is found; but this belongs
chiefly to Pershaw, if not entirely.

The neighborhood of Aberdeen, extending for some miles
north of the city, is chiefly low land; towards the west, is occupied
by granite. The limits of this granite district do not appear to
be well ascertained, but it extends westward as far as Midmar
parish, and is found even as far as Coul and Tarland parishes.
The principal mass of granite forms rounded hills west of
Aberdeen between the Don and the Dee, and extends to the
northward of the Don. The granite is neither very coarse
nor very fine grained. It is quarried in large quantities
(chiefly of grey granite), and shipped at Aberdeen for London
and other parts of the kingdom.

Granite is found in various other parts of the county; in
the parishes of Kelg, Prenmary, Monymusk, Orne, Daviot, and
Chapel of Garioch, near the banks of the Don, and of the
Ugie, between the estuary of the Dee and Udny, Elsick, and
Teres, near the banks of the Ythan; in those of Huntly,
Drumballe, and Glenbuchet, near the Doveran; and in those
of Fraserburgh, Longside, and Peterhead, near the coast. It
is quarried in Drumballe and Peterhead parishes. The granite
is found in many places along the coasts, especially in the state
as to be easily dug into by the pickaxe and spade; yet
large blocks of fine building-stone, capable of resisting the
action of the weather, are frequently quarried in the midst of
a mass of distinguished mica. Granite is found in various parts,
especially in the parishes of Peterhead and Lunmey near the coast; in
Alford and Methlick parishes in the interior; and in Strathdon and Glen-
buchet, near the head of the Don. Granite is found in the
district adjacent to the granite, but not in great quantity.
The predominant rock in the county is mica slate. In the

parts adjacent to the granite it is quartzose and very compact,
showing a tendency to pass into gneiss, or alternating with
that rock. Serpentine and primitive limestone are found in
a few places. Clay slate, granuvack, and granuvack slate are
found in the parishes of Tarland and Udny; and the granite
and hilly parts of the county; and veins or dykes of trap
are observed in parishes near the east coast. (Boi., Essai Geo-
logique sur l'Écosse; New Statistical Account of Scotland.)

The Dee rises in the south-western part of the county, in
the mountains which there separate Aberdeenshire from In-
verness-shire. It rises high up the side of the mountain Brec-
ach, at an altitude of about 2000 feet, and flows for about
11 or 12 miles in a south-west direction to the junction of the
Geonny or Geusay, a stream 10 miles long. From the
junction of this stream its course is east by north for about 12
miles to Newton, below the castle of Braemar. In this part
its course is through a mountainous district; it flows past
the Quaich or Coich, each about 10 miles long, on the
left bank, and the Ey and the Chumie or Clanaught, at the
same length, on the right. In the upper part of the Dee there
are several falls of about 60 miles to its outlet at Aberdeen.
Its whole course is above 90 miles. In the ' Gazetteer of
Scotland,' published by Fullarton and Co. of Glasgow, and in
Chamber's 'Gazetteer of Scotland,' its length is estimated at
90 or 97 miles. About 24 miles above its outlet it quits Aber-
deenshire to enter Kincardineshire; but flowing about ten
miles through Kincardineshire, returns to the border of Aber-
deeshire, and for the rest of its course separates the two coun-
ties. It receives the Gairden or Geirn, 18 miles long, on the
left bank; the Cruises, 10 miles long, on the right bank; and
Loch Muick, 12 miles long, on the right bank, about two miles
lower down. In the upper part of the Muick there are two small but picturesque
lakes. Dhu-loch, 'the Black Lake,' is supposed to obtain its
name from its being overshadowed by the lofty cliffs of Craig
Dhu-loch, which rise from its shore, and are marked by
steepness of more than 1000 feet. A mountain rill falls into it on the
north side from a height of more than 900 feet. Loch Muick
is about two miles long, from south-west to north-east, and
half a mile broad. It receives a stream from Dhu-loch and
others from the surrounding mountains; and its waters are re-
markable for their coldness even in the midst of summer.
There is a small island near its south-western end, where sea-
gulls are always to be found. A little below the Muick,
another stream from the Dee on the west side of the
hill rises to the Don near the head of the river. This is the
outlet of two small lakes; Loch Connor, surrounded by
birch-woods and studded with small islands, and Loch Dawn.
The Dye, the largest feeder of the Dee, with the Aven its
head, rises in the mountains, and joins the Dee on the right bank in Kincardineshire. Two small
lakes, Loch Drum and Loch Skene, are connected with the
Dee by streams which flow into it on the left bank, after it
again touches the border of the county.

The Dee rises on the western border of the county, in
the parish of Strathdon; its course is elevated about 1610 feet
above the level of the sea; its course is very winding; first

B 2
north-east, to the neighbourhood of Kildrummy kirk, 30 miles; then eastward, about 28 miles, to Inverurie; and then south-east, about 20 miles, to its outlet in the North Sea at Old Aberdeen. Its whole course is about 76 miles. In the Grampian district, it is called the Dee.

The Trinity is lime, it in flows, here stdl is Aberdeen.

The From and Inverury and is but about the the of.

The Ugie is formed by two streams, of which the North Ugie rises to the south of Aberdour and flows south-west by the kirk of Strichen; the South Ugie rises between Strichen and Marykirk, and thence flows north-east, and enters the Dee to within a little above Elgin. The first and the last two are each about eight miles long, but the middle one is much too little. The Don rises in a peat moss: in the upper part of its course it is a very rapid river, shallow, and subject to inundations, of which that of 1829 was very destructive. The total length of the Don is about 70 miles, and the area of its course, and at the manse of Strathdon is 70 feet wide: it affords excellent angling for small trout. At Keig, midway between Kildrummy and Inverurie, it is 140 feet broad; but still very shallow. At Inverurie it receives the Urie or Ury, which is important, and another small stream, westward. The Don therefore has a course of about 5 miles, south of it, and then enters Aberdeen. Its course now becomes circuitous, first turning eastward and then northward, till after flowing for about 13 miles through Aberdeen (in which, near the town of Humlit, it receives on the right the north-eastern branch of the Dee), and also three smaller streams, which flows northward 17 miles by Achindore, Keazn, and Garty kirks), it returns to the border. The remainder of its course, about 23 miles first eastward and finally northward, is partly in the county of Banffshire, the whole length is about 51 miles. It is a rapid stream, flowing for a considerable part of its course through a deep, narrow valley, and is subject to serious floods. Both the Bogie and the Deveron contain excellent trout; pearls of trifling value are contained in the river, and there are some valuable fisheries, near the town of Ernie,

A considerable salmon fishery is carried on. The burns of Turriff and King Edward (13 miles and 9 miles long respectively), which join the Deveron on the right bank, belong to Aberdeen; the more impotantly on the right bank. The whole length is therefore 31 miles.

Of smaller streams, the Cruden, about 8 miles long, flows into the North Sea between the Ythan and the Ugie; and the Rathen, which rises in Caimhul. It enters by Kinnaird's Head, near the town of Fraserburgh. Aberdeen does not contain any lakes of importance. Dhu-loch, and Lochs Muick, Cannor, Dawan, Drum, and Tom in the county of Banff, have been already mentioned in our notice of the river Dee.

The only canal in the county is the Aberdeen canal, which begins in the harbour of Aberdeen and runs up the valley of the Don parallel to the course of the navigable near to it on the right bank, and terminates at Port Elphinstone in Kintore parish, but close to the town of Inverurie. This canal was formed under acts obtained in 1793 and 1796, and was opened in 1807: its length is 184 miles; its width originally 17 feet and its depth 3 feet, but these dimensions have been enlarged, so that it is now from 21 to 23 feet wide and 34 feet deep. Another statement gives the breadth as averaging 25 feet, the depth 34 feet. The expense of the construction of the former work was about £35,000, and the latter £5,000. A lock is placed at Inverurie, and there are two other locks, the greater number of which are at the lower end of the canal within 3 or 4 miles of Aberdeen. The total fall is about 133 feet for water mark in Aber- donna harbour. The trager of the canal has been on the whole increasing: lime, coal, dung, bones, and bark are carried up, and stone, slates, grain, and meal brought down. A passage boat runs daily from Aberdeen to Port Elphinstone.
Aberdeen up the valley of the Dee by Peterculter, Drumoak, Kincardine O'Neil, Beauchief and Maybole, Braemar; and from thence southward across the Grampians to Blair Gowrie and Perth. From Peterhead by Longside and Old Deer to Banff.

Soil and Agriculture. — The soil of the county varies much. Considering it is a part of the west of Scotland, it is heavy and clayey in the northern parts, and sandier and lighter in the southern; but there are considerable tracts of the western part of the county which are well drained, and whose soils, though of a light nature, are worked to considerable advantage. The clay in the eastern part of the county is very much inferior to the yellow clay found in the south of Scotland, and it does not afford good pasture. The eastern part of the county is well watered, and the streams are generally navigable. The western part of the county is covered with oak and beech, and the eastern part is covered with pine and fir. The forests of the county are well laid out, and are worked with great advantage. The county is well supplied with timber, and the timber is of good quality. The forests are well managed, and the wood is cut in a systematic manner. The forests are well stocked with game, and the hunting is excellent. The county is well supplied with water, and the water is of good quality. The county is well supplied with coal, and the coal is of good quality. The county is well supplied with iron, and the iron is of good quality. The county is well supplied with lead, and the lead is of good quality. The county is well supplied with silver, and the silver is of good quality. The county is well supplied with gold, and the gold is of good quality. The county is well supplied with copper, and the copper is of good quality. The county is well supplied with tin, and the tin is of good quality. The county is well supplied with zinc, and the zinc is of good quality. The county is well supplied with lead, and the lead is of good quality. The county is well supplied with silver, and the silver is of good quality. The county is well supplied with gold, and the gold is of good quality. The county is well supplied with copper, and the copper is of good quality. The county is well supplied with tin, and the tin is of good quality.

The united parishes of Braemar and Crathie, containing about 200,000 acres, or 312 square miles, comprehend the highlands about the source of the Dee. This district has a variable but healthy climate, and is watered by a number of mountain-streams, affording a level and healthy pasture to the deer. The prevailing winds are from the south, and the forest of the month is, for size and quality, the first in the British Islands. This forest is well stocked with red-deer and roes: it affords also good pasturage. The quantity of culivated land is very small, but the landlord is much interested in the prevalent breed of sheep; and the small black-bred horned cattle of the county. The adjacent highland parish of Strathdon (about 67,300 acres, or 105 square miles) has less natural wood; and the land is chiefly birch. The soil in the strath or valley of the Dee, in the eastern part of the county, is generally composed of clay, sand, and gravel. The tops of the hills are covered with meadows of considerable extent. The quantity of arable land is about 4500 Scotch acres, and there are 3500 acres of plantation, chiefly larch and Scotch fir. Agriculture has been conducted in the county with much energy and success for many years; and much land has been brought into cultivation by trenching and drainage. Lime is the general manure, and an abundance of it is good quality dug in the parish, and each farm has commonly its lime-kiln. The usual rotation of crops occupies seven years; oats are grown for two successive years, and are succeeded by turnips or some other green crop; the green crop is followed by bear or bigg, and hay; and the land is used for pasture for the two remaining years. No wheat and but little English barley is grown; the Angus and Scotch barley oats, and the green and red topped yellow turnips, are the favourites. The turnips are excellent: the soil suits the potato, but the danger of rot to the crop from the early frosts prevents the cultivation of it. Losses are generally for nine years in ten, but sometimes as great as 40 per cent.: small crops are generally of a superior description, built of stone and lime, with slated roofs. There are several threshing-mills in the parish, in which water is the moving force.

Glasgow, Kinross, Kinclaven, Alford, and Tough occupy a considerable district between the Don and the Dee, midway between the sources of those rivers and their outfall. The area of these parishes may be stated in round numbers at 50,000 acres, probably more; of which 16,000 acres, or about two-fifths, are under the plough, and about 6300 acres are occupied by plantations. The principal farms are held on lease for nineteen years; and the rent of arable land may be stated at an average of from 14s. to 21s. per acre, according to the quality of the soil, and the offices are generally of a superior description, built of stone and lime, with slated roofs. There are several threshing-mills in the parish, in which water is the moving force.

The general phenomena of the county are the result of the climate, the soil, and the geology. The climate is mild and temperate, with a moderate temperature of heat and cold, and a moderate rainfall. The soil is of various kinds, consisting of clay, sand, and gravel. The geology is of various kinds, consisting of sandstone, limestone, and coal. The county is well supplied with water, and the water is of good quality. The county is well supplied with coal, and the coal is of good quality. The county is well supplied with iron, and the iron is of good quality. The county is well supplied with lead, and the lead is of good quality. The county is well supplied with silver, and the silver is of good quality. The county is well supplied with gold, and the gold is of good quality. The county is well supplied with copper, and the copper is of good quality. The county is well supplied with tin, and the tin is of good quality. The county is well supplied with zinc, and the zinc is of good quality. The county is well supplied with lead, and the lead is of good quality. The county is well supplied with silver, and the silver is of good quality. The county is well supplied with gold, and the gold is of good quality. The county is well supplied with copper, and the copper is of good quality. The county is well supplied with tin, and the tin is of good quality.
London market, and the consequent increase of stock; and this extended cultivation has been aided by the introduction and general use of bone-dust, which is found to answer admirably as a manure for light soils that have been long under cultivation, and has contributed, as far as the clayey soils, and on the lighter soils in combination with bone-dust. The kinds of turnips grown are the green-top and red-top, with yellow bottoms; the rats bags, chiefly for feeding in May and June; and a few tankard turnips. The measures of cartage have been increased, and Manchester, and the in-lands parish. The breed of horses has been improved by the introduction of superior Clydesdale mares and other west-country broods. The cattle were formerly chiefly of the black Aberdeen breed, and Angus. In the latter half of the 18th century the Teeswater short-horned cattle have been gaining ground, being valued as attaining to earlier maturity and greater size. Sheep-farming is not much attended to. The farm-houses of modern erection are generally of two stories, built of stone and lime and covered with slate, neatly finished and comfortably fitted up, approached by smooth roads of easy ascent, in place of the steep and rugged tracks that formerly led to them. The formation of new turnpike-roads and the improvement of other roads have been important aids to the general advancement of agriculture.

Division, Towns, &c.—The county comprehends the five antient districts of Mar, Formartine, Buchan, Garioch, and Strathbogie, which are not at present recognised for any administrative purposes. The county comprehends that part of the county which lies south of the Don: it is subdivided into Brae-mar, Mid-mar, and Cro-mar. It gives the title of earl to a branch of the family of Erkina. Formartine is comprehended in the burgh of Aberdeen on the south coast between the Don and the Ythan and extends inland up the right bank of the Ythan to the border of Banffshire; it gives the title of viscount to the earl of Aberdeen. The district of Buchan comprehends that part of the county which lies north and north-east of the Ythan; but the eastern part of Buchan appears to have also included Formartine. The title of earl of Buchan still belongs to a branch of the Erkina family. Garioch is an inland district, about the Urie and its feeder's notches as of Kildrummy and as the modern designation of the ancient parish of Garioch. Strathbogie is an inland district, comprehending, as its name indicates, the valley of the Bogie, one of the affluents of the Deveron, and also including part of the valley of the Deveron itself near the junction of the Bogie. At present the county is divided for administrative purposes into the eight districts of Aberdeen, Alford, Deer or Buchan (comprehending only a part of the more antient district of Buchan), Ellon, Garioch (more extensive than the antient Garioch comprehended by the crown in 1568 than the older Strathbogie), and Strathbogie. These modern districts are nearly coincident with the several presbyteries of the same name. The population of these districts at the enumerations of 1831 and 1841 was as follows:

The county contains the city and royal and parliamentary burgh of Aberdeen, the population of which, in 1841, within the parliamentary boundary, was 68,286 [Aberdeen]; the royal and parliamentary burghs of Inverury, Kintore, and Peterhead; the towns of Formartine, Alford, Ellon, Aberdeen, and Inverury; the barony of Charleston, Fraserrgh, Huntly, Old Meldrum, Rosehearty, and Turriff.

Inverury is in the district of Garioch, 16 miles north-west of Aberdeen, on the left or north bank of the Don, in the angle formed by the junction of the Urie. There is a substantial modern bridge over each. The town consists of a long straggling street, running from south-west to south-north. The church, built in 1775 for 700 persons, is insufficient for the increased population; and a new church of Gothic architecture, sufficient for more than 1,000 persons, was in 1842 in course of erection: there is a neat Episcopal church, built in 1842; and places of worship for Independents and Methodists. The population of the burgh, which includes the town and the suburb of Port Elphinstone (which is in Kintore parish), was, in 1841, 1619; that of the whole parish (including Port Elphinstone), 2059, having been quadrupled within the present century; the burgh had 289 houses, namely, 274 inhabited, 10 uninhabited, 5 building. The opening of the Aberdeen Canal has much promoted the prosperity of the place. It has twenty large horse, cattle, and sheep fairs in the year, held every fortnight in summer and in winter. The town and its privileges were renewed by a novadomas, A.D. 1558; and it was made, in 1868, head of the earl of Mar's regality of Garioch. The burgh has a provost, three bailies, a dean of guild, a treasurer, and three councillors. It is included in the Elgin district of Parliamentary boroughs, and had in 1832-4 a constituency of 78, and in 1839-40 of 94. There are in the parish, the parish school, with about 50 scholars on the average; and five other schools, chiefly kept by females, for reading, sewing, and knitting. There is a savings-bank.

Kintore is in the district of Garioch, 12 miles north-west of Aberdeen, in the peninsula formed by the Don (which here flows in a very winding channel to the south-east), the burn of Tuach, which joins the Don on the right bank, and the Ythan, which, on the left bank of the Don, consists chiefly of one street, running from a bridge over the Tuach burn from east-south-east to west-north-west. There is a bridge over the Torry burn, and two bridges over the river Don. The burgh will accommodate 700 persons, stands in the town, and there is a town-house, a respectable building. The burgh, which comprehends the town, contained, in 1841, 102 houses, namely, 98 inhabited, 3 uninhabited, 1 building; and a population of 464 persons; the whole parish, of which the greater part is farmed by a provost, the smaller part being a grant. The population of the parish is 1299, including the population of Port Elphinstone (112 persons), which is in this parish, though comprehended in the burgh of Inverury, and the population returned with it. The town of Kintore has been excavated, and a new bridge is being made close to the town, and upon which there is a wharf: lime is brought up from Aberdeen, and granite carried down. There are several good shops in the town, and at Port Elphinstone are a number of grain-mills, two saw-mills (one moved by steam, the other by water), and some granaries, timber-yards, and storehouses. The burgh is very ancient: tradition states that it originated in the time of Kenneth II., but this is utterly unlikely: there is a charter of confirmation by the burgh from Robert II., 1318, and its ancestors had, before the Burgh Reform Act (which did not affect this burgh), held the provostship for a century and a half, and paid all the burgh expenses. Kintore is a contributory borough to the Elgin district of Parliamentary burghs, and had in 1832-4 a constituency of 78. There are a parochial school and several private schools in the parish: a school at Port Elphinstone has a school-house built by government, but no endowment: in all the schools together there are about 200 scholars, two in thirteen of the whole population. There are two Sunday-schools, one at Kintore and one at Port Elphinstone. There are a circulating library and a savings-bank at Kintore.

This title is given to the title of earl to a junior branch of the Keith family. The earl was created a baron of the United Kingdom in 1858. Near the town on the south are the remains of Hall-forest Castle, said to have been built by King Robert Bruce, and to have been a hunting-seat of the kings of Scotland: there is a buildings in the place. In the vicinity there are traces which show that it was once of larger dimensions.

Petershead is in the district of Deerness, on the east coast, 32 miles north-west of Aberdeen, on the peninsula running south-eastward into the North Sea, on the south side of the mouth of the Ugie: the two harbours, the New North Harbour and the South Harbour, are near the south-eastern extremity of the peninsula, in opposite sides of which they are separated or otherwise forming by a neck of land. The North Harbour is the oldest, having been formed in 1773, according to a plan of Mr. Smeaton, afterwards extended by Mr. Rennie, and covers about six and a half standard acres; the New North Harbour was formed in 1836, from a piece of Mr. Telford, and includes almost eleven acres: both harbours are furnished with quays and protected by piers. The town occupied, in 1840, a

part of the parish has been formed into a separate parish
' quoad
sacra ;' connected with .the church of which is a congregational library of 240 volumes.
Peterhead is frequented
as a bathing-place: it has several mineral-springs of some
reputation.
Near the town are the remains of two antient
castles, Ravens'-crag and Boddam
the former is the more
antieat.
The Pretender landed at Peterhead in disguise in
the rebellion of 1716.
Charles town or Charleston, distinguished as Charleston of
Aboyne, is in the parish of Aboyne and Glentaner, in the
district of Kincardine O'Neil, near the Don, 20i miles west
of Aberdeen. It is a very small place, having, in 1841, 66
houses), namely, 61 inhabited and 6 uninhabited, with a population of 260: the population of the whole parish was 1138.
The Tillage has a few shops, a commodious inn, and a postoffice : there are five great markets in the year, held on a
green near it. The church is about a quarter of a mile west
of the village, and will hold above 600 persons. Near it is a
suspension-bridge over the Don, erected by the Earl of Aboyne
at bis
expense, in the place of one destroyed by the great
floods in 1829 : the suspension part is 230 feet long, and there
are two trussed iron arches of 50 and 60 feet span respectively
and two stone arches of 20 and 30 feet. The parish school
had, in the winter of 1841-2, 140 scholars. There is a pretty

Broad sea, was, in 1 841, 725, of which 714 were inha7 uninhabited, and 4 building (he population was 8289,
or including Broadsea 36 1 5. The town was not, in the return,
distinguished from the rest of the parish
Many of the houses in
the town are comfortable and even elegant. The town-house,
the market-cross, and the tolbooth (the last now falling into
ruins) were all erected by Sir Alexander Fraser mentioned
above.
The cross to a stone pillar, 12 feet high, erected on an
hexagonal base, and is surmounted by the British arms and the
armorial coat of Fraser of Philorth. The parish church is in the
middle of the town
it was built in 1802, and will hold 1000
people it has a spire. There are an Episcopalian chapel and
an Independent meeting-house. The n arbour is formed by
three piers : a north pier 300 yards long, begun in 1807 and
finished in 1 8 1 2 a south pier of the same extent, built under an
act obtained in 1818
and a middle pier erected since, broader
and ' superior to the other two.' The extent of the harbour
is above six Scotch acres
the depth of water at the pierheads six feet at low-water and twenty feet at high-water of
spring-tides.
The bay affords good anchorage. There is a
lighthouse on Kinnaird's Head.
little rope and sail making
is carried on in the town
barley, oats, ana potatoes of good
;
quality, cattle, and dried and pickled cod and herrings are exported
and timber, coals, lime, bricks, salt, and general merchandise are imported.
Eight vessels of from 45 to 165 tons
burden, belong to the port
and there are 220 boats engaged in the nerring fishery, which employs 1600 people.
This branch of industry was first extensively prosecuted in
1815 ; it begins in July and lasts till September ; and during
its continuance the population of the place it augmented by
1200 persons from other parts, and the town and harbour
present an aspect of unwonted bustle.
Some freestone to
quarried in the parish, of which the piers and some of the
houses are built ; and there are mineral-springs, one of which

some repute as a tonic. There are in the parish the
two antient chapels, one of which, called < the College,' belonged to the Cistertian abbey at Deer. There to also
at the west end of the town an old quadrangular building of
three stories, designed by Sir Alexander Fraser for a college
he had obtained a charter from the crown in 1692, for the institution and endowment of a college and a university ; but the
plan was never carried into effect. All the proprietors of houses
in the pariah are feuars of the borough, of which Lord Saltoun is the superior, with the authority of provost, and the
right of nominating the council and magistrates with the
advice and consent of the existing council.
The burgh
officers are two baillies, a dean of guild, a treasurer, and seven
councillors.
There are in the parish a parochial school, with
an average attendance of 100 scholars, 20 to 30 of them girls
and several day-schools, chiefly female or dame schools:
there are about 600 children at the day-schools, including the
parochial ; or about one in seven of the whole population
and about 300 attend the Sunday-schools, of which there are
eight.
There are a savings'-bank and a parochial library.
Huntly to in the district of Strathbogie, on the south-east
side of the Deveron or Doveran, in the angle formed by the
junction of the Bogie, 38 miles north-west of Aberdeen on the
road to Inverness.
It is a burgh of barony under the earls
(now marquises) of Huntly. The town to surrounded by bills,
and consists of streets regularly laid out and lighted with gas,
the two principal intersecting each other at right angles, with
to

in

ruins of

a square or market-place at the intersection. It had, in 1841,
696 houses, namely, 576 inhabited, 18 uninhabited, and 2 building ; with a population of 2731. The population of the whole
parish was 3642.
The parish church, built in' 1806, will
accommodate 1800 persons; and a new church, which will
hold nearly 1000, was erected in 1840 there are Roman Catholic and Episcopalian chapels, and meeting-houses for Independents and Associate Seceders. There are two good bridges,
namely, an antient bridge of one arch, over the Doveran, and a
bridge of three arches over the Bogie: Near the town stands
the now deserted Huntly Castle, built in 1 602, out of the ruins of
;

Fraserburgh is in the district of Bach an, on the north coast
of the county, 42 miles north of Aberdeen, 18 miles north- the more antient Strathbogie Castle adjoining to it. There to
north-west of Peterhead, and 22 east of Banff, to all which also Huntly Lodge, now enlarged to a handsome house, and
places there are excellent turnpike-roads. The town is built occupied by the Dowager Duchess of Gordon. There are in
on the western side of the small bay of Fraserburgh, bounded or near the town a bleach-field, a tanyard, a distillery, and
on the south-east by Cairnbulg Point, and on the north-west by three banks. There to a weekly market on Thursday. ButKinnaird's Point. The parish was originally called Philorth, ter, eggs, cheese, pork, poultry, and game are sent from the
a town and harbour having been built, and a burgh of town and neighbourhood. There are about 12 yearly fairs or

time of the year, the 'new school' connect with the new church, with 128 scholars, an infant-school with 80 scholars, and a sewing-school with 30 scholars. The church is a pulpitless building erected for educational purposes by the Duchess of Gordon. There are besides an excellent girl's board-school with 40 pupils, and several other private schools chiefly kept by females. There are 80 children enrolled in the term, or nearly one in five of the population. There are also several Sunday-schools in connexion with the Established churches, or with the Independents and Roman Catholics. The county parts of the parish are not so well provided with schools; the only church school is in the district of the Duke of Richmond, who is proprietor of nearly the whole town; a farmers' agricultural library, an evangelical subscription library, a coffee and reading room supplied with one or two periodicals. There are two savings-banks, a savings' bank, and a friendly society connected with the total abstinence society.

Old Meldrum is in Meldrum parish, in the district of Garioch, 16 miles north-east from Aberdeen on the road to Boddam. The parish had, in 1841, 427 houses, namely, 420 inhabited, 6 uninhabited, and 1 building; with a population of 1875. The town is not distinguished in the return from the rest of the parish. Old Meldrum was erected into a church in 1821. There are two magistrates and 14 sworn or unsworn officers now. The town-house and the town-hall are respectable buildings. The parish churcb is close to the town: it was built in 1710, and has been since enlarged so as to hold 700 persons; but it is still too small for the increase of population within the last 20 years. There is a remarkable burial-ground, an Episcopalian and an Associate Secession meeting-house. There are a distillery and a brewery in the town, and two weaving-shops for cotton goods, rented by manufacturers at Aberdeen, in which some of the young people are employed at handloom weaving. There is a second distillery in the parish. There is a good weekly market for provisions, and a corn and cattle market every fortnight in winter and spring. There are a parochial school in the town, and three private schools, one of them for girls, in the village. The average income is about £371. There is a savings'-bank. On a farm called Chapel House, in the parish, there are the remains of a Roman Catholic chapel standing in a burial-ground, which has only been disused within living memory. The traces of a small Roman camp have been obliterated lately.

Rosebearty, in Pitalo Parish, in the district of Buchan or Deer, is on the north-east coast of the county, about 4 miles west of Fraserburgh. It was created a burgh of barony by royal charter in 1581. Mr. Dingwall of Bucklaw and Corriodar, who is the landlord, is superior to the burgh, but the burgh has no magistrate or public officer, and the tolbooth has become private property. There is however some property belonging to the burgh, which is managed, with the assistance of four burgh officers, each an individual and holder of a debt of 200L. The church, built in 1634, is a spire, and will hold about 500 or 600 persons. It is not stated whether it is within the burgh limits: but there is a meeting-house for the Associate Seceders in the burgh. The burgh in 1841 had 188 houses, namely, 182 inhabited, 3 uninhabited, and 3 building; with a population of 750. The population of the whole parish was 1592. There is a good harbour for vessels not exceeding 70 tons. It has 9 feet water in nap at spring tides, and three vessels belong to the port, besides fishing-boats. The herring fishery employed, in 1838, 40 boats with five men each, or four men and a boy, besides seven vessels to attend the fishery. Cod, ling, haddock, skate, saltry, pollack, and a small black fish are also fished. The fish are sent to London, Edinburgh, or Glasgow. In March several of the fishing-boats return to the Isle of Tyree in the Hebrides to fish for cod, and sell their cargoes at Glasgow, from whence they bring back to their burgh 250 barrels (34 tons) of cod liver oil is exported. A fishing-harbour has been lately formed at Sandhaven in the parish east of the burgh. There is a weekly market at Rosebearty on Saturday, and a post-office, a branch of that at Fraserburgh. The parochial school has a little chapel and a cell, but it is not attended. There are parish six other schools (five of them taught by females), with an average of 30 scholars each. There are several friendly societies in the town.

Turriff is about 11 miles south of Buchan, on the Turriff burh, which joins the Dovenan. In 1841 it had 312 houses, namely, 306 inhabited and 6 uninhabited; with a population of 1859. The whole parish was 3146. The parish church, a handsome structure, was built in 1794, and has been since enlarged. The remains of the old church, which was built before the Reformation, is still there. The present building is separated from the burial-ground by a wall, and the burial-ground gate are the vaults of an ancient tower. There is an Episcopalian church and an Independent meeting-house. A cross of considerable antiquity stands in the principal street, and is supported by classical steps rising to a height of 20 feet from the ground. There are several considerable mansions in the neighbourhood, especially Delgatie Castle and Towie Barclay; and there are two bridges, one close to the town, over the Turriff burn, and one over the Dovnan, both built by the burgh. Some lead mines are worked, but not so extensively as formerly. There is a small woollen cloth manufacture: some silk and woollen dyeing are done; and some worsted stockings are knitted. There are some good shops. There are a settlement of fishermen, a post-office, and a local post-office. There are eight yearly fairs for corn, cattle, sheep; and feasting markets at Whitesundae and Martinmas for hiring servants. Turriff was created a burgh of barony by charter in a.d. 1511, with a grant for markets and fairs. The parochial school has generally more than 100 scholars, and there are several dame or other private schools. There are about 400 children, or one in eight of the population, at school. There are five Sunday-schools, three in the town and two in the parish, with 100 subscribers and 600 volumes, an agricultural library, and a small savings' bank. The sheriff's office holds a small debt court quarterly, and there is a small lock-up house for temporary confinement. The first blood drawn in the great civil war of Charles I. was in the parish of Turriff, when the Royalist nobles and gentry in 1649 dispersed 'the committee of the tables' assembled in the town.

The following villages may be briefly noticed. Ballater, in Clunie parish, north-east of Aberdeen, on the north bank of the Dee, is of recent origin, and is much resorted to on account of the beauty of the situation and the mineral springs of Pananick in the neighbourhood: the houses are regularly built and neatly fitted up for lodgers, and amounted to 94 in 1841, 74, namely, 37 inhabited, 10 uninhabited, and the population was 371. The parish church is in the village, and there is a post-office. The springs or wells of Pananick, about two miles east of the church, are four in number, all dyable, and the water there is lodgings at the wells, also hot, cold, and shower baths. The resort of visitors in the summer is very considerable, and it is at present the most fashionable bathing-place in the north of Scotland. Two stone bridges of five arches, over the Dee, have been carried away by the floods in the last half century by the floods to which the river is subject; the first was destroyed in 1799, the second in the great floods of 1829: at present there is a neat substantial wooden bridge of four arches. Boddam or Boddan, the village, is 4 miles north-west of Peterhead parish, in the district of Buchan, is near Buckie, and is a lighthouse of granite 118 feet high. It was built a.d. 1824, and has a flashing light. This lighthouse is on an island connected with the mainland by a beach of round stones, separating the north and south coast-barbour of Boddan; the south barbour will receive ships of a moderate draught of water. The population (626 in 1841) of Boddan consists chiefly of fishermen and their families. Newburgh, in Foveran parish, in the district of Ellon, north-east of Aberdeen, in 1841 had 94 houses (namely, 91 inhabited, 2 uninhabited, and 1 building), and a population of 393. The New Statistical Account of Scotland makes the houses 120 and the population 450. Several of the houses are substantial and commodious, with chimneys and windows. The village stands on the banks of the river Ythan, which runs past the village, and is a mile and a half wide. It was the ancient capital of the Ellot tribe. The village stands on the banks of the Ythan, the mouth of which forms the port of Newburgh, to which vessels go, with an aggregate tonnage of 646 tons, 767 long tons, 256 short tons, 505 tons of coal, and 13 tons of lead. There are several fisher boats. 12 of them are bone-mills, several granaries, a savings'-bank, and a shipmasters' friendly society. Newbyth or New Byth, in the parish of King Edward and the district of Turriff, is 1 mile south-west of Ellon, a hollow village, with three roads meeting one another near the right angles. It is the centre of a quoad sacra parish, which in 1841 had 326 houses, namely, 310 inhabited, 10 uninhabited, and 6 buildings; with a population of 1809, of whom there are 1721 persons. There is a chapel of the establishment, a subscription library, two inns, and a distillery: there are three fairs in the year. Strichen, Mormond, and New Leods are in the parish of Strichen, in the district of Buchan. Strichen is well built, and has a neat
town-house, a commodious church, a branch bank, a savings' bank, and a post-office. There are five yearly fairs; one was established for the sale of yarn, but the cultivation of flax and the sale of yarn, formerly extensive, have much declined. Mormond was laid out in 1764, and is regularly built with a number of large and handsome houses. In 1836, the population of New Leeds was 7,203; that of the other villages was not distinguished in the return. Sturfa, or Stewartla, in the parish of Couvinnedale, in the county of Banff, was burnt in 1832, and now consists of a mere village, namely, 174 inhabited and 8 uninhabited; and a population of 614. Several persons are employed in the manufacture of linen yarn in the village; and in it or in other parts of the parish are lint-mills, mills for making woolen cloth and yarn for the worsted trade, fulling-mills, &c. In the parish there are five fairs in the year, two of them horse and cattle fairs, whose consequence, the other three are unimportant.

Divisions for Ecclesiastical and Local Purposes.—The county is for the most part included in the jurisdiction of the Synod of Aberdeen, which comprehends, in addition, nearly the whole of Banffshire and part of Kincardineshire. The Synod of Aberdeen comprehends the following eight presbyteries: Aberdeen, which includes that portion of Kincardineshire that is built in a substal; Alford, which extends into Banffshire; Deor, Elkin, Fordyce, which last is wholly in Banffshire; Garioch, Kincardine O'Neil, which extends into Kincardineshire, and Turriff. The Presbytery of Strathbogie, which is under the lordship of the earl of Buchan, is partly in Banffshire, partly in Kincardineshire, and wholly in Banff. The number of parishes wholly or partly in this county according to the Population Returns of 1841 is 90. These are parishes both for ecclesiastical and civil purposes. There are besides 14 'quoad sacra' parishes, where also the administration of the church is vested. There are about 30 churchyards and constituted distinct parishes for ecclesiastical purposes alone; 10 of these quoad sacra parishes have been formed in the city of Aberdeen. Dissenters from the establishment are secure, and are chiefly in and about Aberdeen, and in the districts and presbytery of Deer or Buchan; in other parts they are not numerous; they consist of associate or other seceding Presbyterians, Episcopalian, Independents, and a few Roman Catholics and Unitarians, the last in the city of Aberdeen, with a town and a parish.

There are two universities, namely, King's College in Old Aberdeen, founded in the fifteenth century, by Bishop Elphinstone; and Marischal College in New Aberdeen, founded by George Comyn, fifth Earl Marischal, in the sixteenth century.

[ABERDEEN, P. C.]—The shire is well supplied with schools; nearly two hundred are enumerated in the table given at the end of the county in the New Statistical Account; but this amount is far below the truth, as the whole city of Aberdeen, and about twenty-six parishes in other parts, are omitted in it.

There are a county prison and a bridewell at Aberdeen. There are small hugh prisons at Old Aberdeen, Old Mel-drum, and Old Tarland, as Pethead, but these are used only occasionally and for very brief confinement. There is a new prison at Peterhead, which town is the seat of a sheriff court; but the prison had not been completed at the time of the Fourth Report of the Board of Directors of Prisons, presented to parliament in 1848. It was then in the contemplation of the Board to provide small prisons at Fraserburgh, Huntly, and Tarland, as the small hugh prisons were not under their direction. The gaol of Aberdeen is situated in a healthy situation, it is secure, clean, well ventilated, and dry; it contained in 1836 ten day-rooms and sixty cells. The discipline and management at the time of the First Report of the Inspectors of Prisons (1836) were not satisfactory; but considerable improvements have taken place since then, and the separate system, for which the building affords opportunity, has been carried out successfully. The hewdewell of Aberdeen is a substantial building, in an apparently healthy site; it affords a sufficient number of sepulchral monuments, the separation of the cells is not such as to render the separation perfect; the management at the time of the Prison Inspectors' Second Report (1837) was decidedly good.

P. C. S. No. 2. A cause of crime, is believed not to have increased in proportion to the population, though it is still prevalent. The police about Aberdeen has been much improved.

(Reports of Inspectors of Prisons, especially First and Second, and of Board of Directors of Prisons.)

The county of Aberdeen was annexed to the parliament by the Act of Union (1707). The number of electors of all qualifications was, in 1835-36, 2986; in 1839-40, 3181. The city of Aberdeen returns one member; the constituency in 1835-36 consisted of 2242; in 1839-40, of 2775. The county of Aberdeen was included in the Elgin district of burghs, which returns one member; the other burghs of the district are Elgin, Cullen, and Banff. The constituency has been already given in our notice of the burghs.

History and Antiquities.—At the earliest historical period Aberdeen was occupied by the Taesali (Taealbas) of Ptolemy. The promontory of the Taesali (Taebalos) of the same writer may be probably identified with Kin-naird's-head near Fraserburgh; its rivers Celnias (Kildonan) and Deva (Dyaxia), with the Doveran and Dee respectively; and his city Devana (Dovrea) has been identified by General Roy with Old Aberdeen, and by others with Norman Dykes on the Dee, a few miles above Aberdeen. The south-western part of the county was probably included in the territory of the Vescamag (Oseumagis) of Ptolemy; as Tames (Tama), one of the towns which he ascribes to them, is by some identified with Castletown of Braemar. The Ituna of Ptolemy is probably identified with the town of Frondyce, and his position Ad Iunam with some place on its banks.

Of the most antient period of its history Aberdeenshire contains various monuments; such as Cairns, barrows, Druidical stones, and the structures sometimes called Picts' houses. Some of these remains are of ancient date, and are supposed to be Roman. A singular monument called the Maiden Stone is found in Chapel of Garioch parish. It is a stone pillar, ten feet above ground, and supposed to be imbedded six feet below the surface, by two parallel dikes forming a square, one thick, marked with hieroglyphic or other characters, supposed to be Danish. Its name is connected with a tradition which ascribes the origin of the monument to a love tragedy of the middle ages. There are in the parish of Aberdour and Montrose remains of the Picts' houses. Another Pict's house is marked by stones regularly laid without cement, and partly imbedded in the rock. The enclosure, which is 83 feet in diameter, is on the top of a hill called Knockbeg; this monument is connected with others of a similar character and forming an enclosed way or avenue, the main line of which may be traced for nearly fifty miles, near the north bank of the Dee; some branches diverge in a direction traversing the river and the Grampian Mountains.

The principal period of the middle ages and of later days were—the battle of Cruden, in the beginning of the eleventh century, between the Scots under Malcolm II. and the Danes under Canute, afterwards king of England. In the early part of the fourteenth century Robert the Bruce, king of Scotland, went to Aberdeenshire to chastise Comyn, or Cumine, earl of Buchan, by whom he was surprised when sike in his camp near Inverrury, but whom he defeated, and whose country (Buchan) he subjected to the most fearless devastation. In 1411, during the captivity of King James I. and the regency of the duke of Albany, the bloody battle of Harlaw, in Chapel of Garioch parish, was fought between 10,000 highlanders, under Donald, Lord of the Isles, and the royal forces (lowlanders), under the earl of Mar, by which the country of Banff, which was completly depopulated. In the great civil war of Charles I., A.D. 1644, Montrose defeated the Covenanters under Lord Burley, not far from Aberdeen, which he entered. Monk occupied Aberdeen in 1651; and the troops of the Pretender, under Lord Lewis Gordon, came into the county, and levied contributions on it in 1745. A detachment of the royal forces, sent from the north by Lord Loudoun to relieve the town, was defeated by the rebels at Inverrury in the latter part of that year. The town of Aberdeen, in 1745, was besiegéd by Prince Charles, when he marched northward previous to the battle of Culloden.

The principal memorials of the middle ages are the ruins of feudal castles. On the north coast, between Fraserburgh and Banff, in the parish of Aberdeen, are the remains of the ancient castle of Fraserburgh, which stands on a promontory, the summit of which rises from the sea to the height of above 50 feet, and is connected with the mainland at high-water only by a narrow ledge of rock. Here Henry de Beaumont, the English earl of Buchan, was besieged by Sir Andrew Murray, regent of Scotland during the captivity of King David II., in 1328.
ABINGER, LORD. [SCARLETT, JAMES.]

ABLAIKt (i.e. the Convent of Ablait), the name of several buildings on the steppe of the Middle Horde of the Kirghiz, about 50 miles from the town of Bokonboz and of Kameno-Karagaskaja, both built on the banks of the upper course of the river Irish. The place is in 49° 20' N. lat. and 83° 6' E. long. These ruins are situated near the base of the former convent, in which the priests of the Buddhist religion were lodged. A smaller building had evidently been a temple, as was proved by a great number of idols, pictures on the walls, and manuscripts, which were found here. The fragments of the idols showed clearly that they had reference to the religion of Buddha. Among them were also found some wooden boards, with raised figures on them resembling some letters in the manuscripts: whence it was concluded that they had been used for printing. Some of these boards, as the tenets of the Buddhist religion was not contained in the manuscripts, were golden letters on black paper, and were of great beauty; others were written on common paper, or on the inferior bark of the bee-cherry. Some of these manuscripts were sent to Peter the Great, but without any information respecting them. It is not known whether they had been used by the Buddhists of Kamenogorskaja, nor whether they knew their contents. Not finding in his dominions a person who was able to understand them, he sent them to Paris, whence he soon obtained a translation, or rather a paraphrase, which, however, on closer examination, turned out to be a fabrication, and it was evident that the translator did not understand one word of the language in which they were written. It was afterwards ascertained that the manuscripts were written in the ancient Tangut language, and referred to the tenets of the Buddhist religion. They were found in a hard brick, and were believed to have been the printing-establishment. This fourth was of a diminutive size, and evidently had been used as a kitchen. All these buildings, though they had no great architectural beauty, were very regular, and constructed of excellent bricks. On two sides the buildings were protected by almost perpendicular rocks, and on the other two sides by a wall about ten feet high and eight feet thick. This wall was entirely of brick, but at the time when the ruins were discovered it was not visible, as there the wall was closed very spacious, and evidently destined to receive a great number of tents or temporary huts. It was ascertained that this place had been built about the middle of the seventeenth century by some friars, or the monks of the Songar branch of the Mongols; and apparently he had destined it to be one of his temporary residences. He soon afterwards (1670) was engaged in a war with the Galdan, the khan of the Proper Oolich (Songara, P. C.), in which he was unsuccessful, and by which he was at last obliged to abandon his country precipitously. The state of the buildings, which still contained much furniture, evidently showed that they had been suddenly abandoned. Ablai and those who still remained faithful to him went westward to the banks of the Uri and Wolga rivers, where he frequently surprised and plundered the Calmuck until he was taken prisoner and brought to Astrakhan, where he lived to an old age. Modern travellers who have visited these ruins have found them in a state of rapid decay.
at Brussels, the houses which are now built in London, and
the grounds which are employed as kitchen-gardens round
the metropolis, would not exist, and the profit derived from
this employment of capital would not exist. It would
be transferred to Brussels and to Belgian capitalists. This
would be the immediate effect of the wealthy residents in
London removing to Brussels. The removal of these residents
to Brussels would be the withdrawal of one of the means of
profit to the Londoners and would be a source of national
wealth. Nor can it be shown that the capital which is
now employed in and about London in building houses and
cultivating garden-ground could be employed with equal
profit in some other way; for to assert this would be equivalent
to saying that in any way possible, the wealthy residents
who are employed under all circumstances in a manner equally
profitable. It may be rejoined, that if all or most of the wealthy residents
of London removed to Brussels, English capital would be required in order
that the British people might provide some of their necessities. This may be
denied, and yet it does not remove all the difficulty, for if the resi-
dents were to remove to various towns of Italy, the employ-
ment of English capital would not be required to the same
degree as if they were all to remove to one place, such as
Brussels.

But this is only part of the question. There are numerous
sources of profit arising from the supply of the ordinary wants of
a man and his family, which accrue to the people who reside in
London: such a man is a resident in London, and the other
retail profits of trade. This is obvious in the case of a num-
ber of families quitting a provincial town to reside in London;
the provincial town decays, and that source of profit which is
decided upon from supply to the trade becomes a source of
profit to the trade of London, and thus affects the trade of
the new place of residence. This, which is true as to one place in England compared with
another, is equally true as to England compared with Belgium
or France. If it can be shown equally the amount of wages
which are paid to domestic servants, this will form a very considerable sum.
The savings of domestic servants in England from their wages are
invested in various ways; and such savings are no small profit to the state of
the rich. It will hardly be maintained that all those who would be
employed as domestic servants in London, if the absentees in
France were to come to live in London, are employed with
equal profit to themselves while the absentees are abroad.
London is supplied with domestic servants from the country,
many of whom would be living at home and doing nothing,
if there were no demand for their services in London; and
everything that diminishes such demand, diminishes the
savings of the family which are accumulated. This argument
forms a part of the productive capital of Great Britain.

Those then who maintain that absenteeism has no effect
on the wealth of the country from which the absentee derives
his income, maintain a proposition which is untrue. Those
who live abroad, and who waste the wealth of their country
is so much clear loss to the country of the absentee,
are also mistaken. There are many ways in which the loss
is indirectly made up; but whatever may be its amount, it
would be wise to check absenteeism by any direct means,
and it is not easy to see how it can be checked indirectly in
any way that will produce good.

Since writing this we have seen ' Five Lectures on Politi-
cal Economy,' delivered before the University of Dublin,
in Michaelmas Term, 1843, by J. A. Lawson, L.L.B., in which
the subject of absenteeism is discussed, though from a some-
what different point of view. Mr. Lawson does not agree
with those economists who think that a country can sustain
as injuries from the remittance of本领works and other
proprietors of revenue. He is of opinion that, so far at least
as Ireland is concerned, absenteeism is an economical evil.
His views on the effects of absenteeism are contained in Lect-
ures on Political Economy, p. 122.

ABSORPTION OF LIGHT is that quality in an
imperfectly transparent body, or at a polished surface, by which
some portion of an incident pencil of light is retained within
the body, while the rest is either transmitted through it or
reflected from it.

The different colours exhibited by bodies in ordinary light
are caused by the transmission, or reflection, of such of the
rays as give rise to the perceptions of the colours, the other
rays being absorbed. A body absorbing all the light which
falls upon it would appear to be entirely black, or would be
invasive; while a body reflecting unchanged all the light in-
edent upon it would seem to be entirely white. No bodies in
nature possess however the qualities of absorption or reflec-
tion perfectly; for the most opaque bodies known permit
permitted some light to pass through them, though the body
permitted some to be reflected from them: while those which appear
be the most white, or the most transparent, absorb much of
that which falls upon or enters them; and the same body,
when in different states, absorbs or transmits light with dif-
f erent degrees of absorption.

When light enters into a homogeneous medium, it is pro-
able that its Intensities, at depths which are in an arithmec-
tical progression from the surface of incidence, decrease in a
decreasing geometrical progression; for it is reasonable to imagine that,
in indefinitely thin portions, proportional to its intensity to that surface, the quantities absorbed will bear nearly a con-
stant ratio to those which enter. With this assumption, let
\( a \) represent the quantity of light which falls on the surface
of a body, and let the quantity absorbed be \( \frac{1}{n} \) of that which
enters; then, \( \frac{1}{n} a \) being absorbed in the first portion, the
quantity which emerges from thence will be represented by
\( a - \frac{1}{n} a = \frac{n-1}{n} a \). Again \( \frac{1}{n} \) of this quantity being ab-
sorbed in the second portion, there will emerge from thence
a quantity represented by
\( \frac{n-1}{n} a - \frac{1}{n} \left( \frac{n-1}{n} a \right) = \frac{n^2 - 1}{n^2} a \)
and so on, the emerging quantities being thus represented by
\( \left( n + 1 \right) \frac{n-1}{n} a \); and this, when \( n \) is made indefinitely
large, represents the quantity of light which is absorbed in the
absenteeism of the media. The rays entering through green
branch become more homogeneous; and those which pass
through glass which, of a certain thickness, is yellow, appear
as the plate is successively thicker, to be green, brown, and
red.

In Polarization of Light, P. C., it has been stated that
when common light passes perpendicularly through a
plate of tourmaline (a doubly refracting crystal) whose sur-
faccs are parallel, the emergent light, which is represented
by one of its refracted pencils is partly and the other almost
wholly absorbed; and it follows that the emergent pencil has
less than half the intensity of that which is incident on the
plate. Dr. Wollaston was probably the first who discovered
this effect (Phil. Trans. 1775) although he states, that a wedge in
which the edge is parallel to the axis of the crystal had a colour different
from that of the light which was transmitted perpendicularly to
that axis; and: M. Biot (Traité de Physique, tom. iv. 1818),
having inferred from the ordinary image of a white object,
transmitted through the thinner part of a prism of tourmaline,
observed green, while the extraordinary image is white, that
the difference of colour did not arise from the different
coloured rays being unequally divided between the two pencils,
since the colours of the two images should be comple-
mentary to one another, concluded that the blue and violet
rays which are wanting in the ordinary image are more easily
absorbed in the crystal when they are polarized parallel to its
axis than when polarized perpendicularly to it. Previously
however to the publication of Biot's work, Dr. (Sir David)
Brewster had discovered like phenomena in plates of quartz,
in mica, and in carbonate of barytes. (Phil. Trans. 1814.)

The quantity of light absorbed in tourmaline depends upon
the thickness of the plate, and it is found that the absorption
takes place gradually, as the pencil passes through; for if
a plate of tourmaline be ground to the form of a wedge, whose
sides make with each other a very acute angle, and whose
edge is parallel to the axis of the crystal, then looking
through the sides of the wedge at a candle it is observed that,
neat the edge, the images produced, both by the ordinary and the
extraordinary refraction, have nearly the same degree of bright-
ness and tint; then, on moving the wedge so as gradually
to bring the thicker part between the eye and the candle, the
ordinary image diminishes as gradually in intensity, and at

C 2
roughness allow it to pass off more abundantly than those which are smooth or polished; and the experiments of M. Biot show that the propagation of caloric along a rod of iron does not extend to a distance from the heated body greater than about one thousandth of an inch, and a half that is indetectable by the thermometer. The conducting power differs however in different substances; and, among metals, that which possesses it in the highest degree is silver: below this, in order, are copper, brass, platinum, iron, tin, zinc, and lead. Among non-conducting bodies, such as wood, bitumen, horn, ivory, mother-of-pearl, ivory, hard rubber, bone, ivory, and glass. The conducting power of gold is not well known: by Franklin it was found to be less than that of silver and copper; while, from the experiments of Despretz and De la Grange, for the metals of similar density, that of gold is less than that of any other metal. Count Rumford has proved that the imperfection of the power in solid bodies depends in a great measure on the quantities of air contained within their interstices. He moreover ascertained by experiment that lint, sheep's wool, raw silk, beaver's fur, and hare's fur, were successively lower than each other in conducting power.

Liquids are very imperfect conductors, yet heat passes through them with considerable rapidity. This arises from the freedom with which the particles of a liquid move among one another, and from their expansion by heat, in consequence of which they become lighter; thus, being easily displaced by the colder particles about them, they rapidly carry with them the caloric which they have received from their surroundings. It was shown by Count Rumford that, on mixing with water different substances by which its fluidity, or the freedom of motion among its particles, was diminished, the velocity with which the heat was propagated was increased. For the same reason, when the fluid is regarded as the motion of the particles of liquid was more impeded. For reasons similar to those which have been mentioned, heat is rapidly transmitted through the atmosphere and other aéiriform fluids, though these, as conductors, are probably less perfect than liquids, and are situated in a critical position.

The experiments of Sir David Leslie established the fact that surfaces from which heat radiates with the greatest freedom absorb it most readily; but the late Dr. Ritchie contrived, by means of differential thermometers, the admission by this experiment, of a thermometer enabled to prove that the power of radiation from any surface is exactly equal to that of absorption at the same surface. A hollow air-tight cylinder of tin, having one half of its exterior surface bright and the other covered with lampblack, was fixed in a vertical position at each extremity of a bent glass tube containing a coloured spirit; and midway between these was placed a vessel similar to the others, and like them coated on half its surface. The vessels were then filled with boiling water; then the bright side of one of the first-mentioned cylinders was turned towards the coated side of that which contained the water, while the coated side of the other was turned towards the bright side of the latter, and the two were ratched in caesium or other kindred bodies. Subsequent to the difference in the brightness of the tube, in consequence of the heat absorbed by them, was proved to be equal to the coloured spirit remaining stationary in the tube. (Journal of the R. Inst. No. V. December, 1831.)

It is evident, here, that if the quantity of heat which radiated from the bright side of the middle cylinder were represented by \( n \)th of that which issued from the coated side; the bright side of the cylinder at one extremity of the tube absorbed \( n \)th of the latter quantity, while the coated side of the cylinder at the other extremity absorbed the former quantity, which was the result of the first experiment.

ABUTMENT, in machinery, is a term applied to a fixed point from which resistance or re-action is obtained. In an ordinary steam-engine, for example, each end of the cylinder acts alternately as an abutment for the force of the steam, and it is against this, being kept fixed, that the pistons of the rigid, fixed obstacle, i.e., the end of the cylinder, expands the whole of its elastic force in the opposite direction, against the movable obstacle, or piston. In like way the breech of a gun forms an abutment for the expansive force of the ignited powder; although in this case, the abutment not being absolutely a fixed point, its recoil occasions some loss of power.

Even a rotary steam-engine, with a continuous circular action, must have an abutment to render the force of the steam effective, though in the primitive rotary steam-engine of Hero of Alexandria, which is described by Lardner and most
writers on the history of the steam-engine, especially by Staudinger, who in the 'Histoire de la Machine a Vapeur et des Travaux de la Machine a Vapeur,' p. 12, quotes the original account from 'Heronis Spiritualium Librae Commandioso,' Amst. 1680, p. 66), and in some modern machines on the same principle, the air is made to supply the necessary resistance; as also must all mechanical combinations in which power is transmitted by means of screws, in which it is sufficient to cite as an example the nut in the fixed head of an ordinary screw-press. [Screw-Press, P. C., p. 51. In all these cases an angle may be traced with the use of the term in architecture, explained under ARTICULT, P. C., p. 51. With a similar meaning it is applied in carpentry to a joint in which two pieces of timber meet so that the fibres of one piece run in a direction oblique or perpendicular to the joint, and those of the other parallel with it.]

ABDYNEUS ('Ἀβδυνεύος'), also called Athienus by Eusebius, a Greek historian who is known to us only as the author of the table-land on the Red sea of Assyria ('Ἀσσυρία'), which is lost, with the exception of some fragments preserved in Eusichius, Cyriillus, Synceclus, and Moses of Chorene. From the manner in which these writers mention Abydineus there appears to have been considerable authority. The time at which he lived is not certain: he must however belong to a later period than Beoruss, who lived about a.c. 250; for in one of the fragments still extant, Abydineus mentions Beoruss among his authorities. For an account of his works and of the sources on which he bases his information, see C. Bär's work, 'De Edemotandiae Temporum,' and more completely in J. D. G. Richter, 'Beroii Chaldæi Historiae quae superstunt,' &c., Leipzig, 1826, 8vo, p. 38, &c. and P. C.

ABYSINIA. Since this article was written in the P. C. of Abyssinia has been visited by many Europeans, who have entered it partly by the road previously known, which leads from the Red Sea at Massow to the table-land of Tigré, and partly over the land of Tigré, on the Gulf of Aden. From the gulf of Aden the route has been to Sh Oslo, which route was pointed out in this work twelve years ago as that by which the southern ports of Abyssinia might be reached without much risk [Abyssinia, P. C., p. 57]; and so it has turned out. The accounts of these travellers have thrown a new light on the physical geography of this country, and though there are some large portions which have not been visited, we can now form a tolerably correct idea of the great natural features of Abyssinia.

The eastern part of Abyssinia is a large tract in Eastern Africa. The greater part of it is drained by the principal branches of the Nile. It lies between 8° 30' and 15° 40' N. lat. and between 35° and 40° E. long.

Abyssinia is an elevated table-land. The greater part of it is more elevated above the sea than the general level of the table-land of Anahace in Mexico. The north-eastern edge of the table-land is directed towards the Red Sea, and is from 30 to 60 miles from its shores. Those who navigate that sea observe an apparently uninterrupted chain of high mountains from the harbour of Massow (15° 40' N. lat.) to Cape Rackmeh (15° 40' N. lat.). These mountains form the dividing line of the table-land on the Red Sea. Isolated peaks are also seen from Cape Rackmeh to the Straits of Bab-el-mandeh, but they appear to belong to a ridge which descends on both sides to a low country. From Cape Rackmeh to the edge of the table-land runs westward, but we are not acquainted with its actual position, as the countries through which it runs are inhabited by tribes which are among the most inhospitable in Northern Africa. In the vicinity of Lake Halik (near 11° 25' N. lat. and 40° E. long.) the edge of the table-land descends rapidly, but over it is not so steep as along the Red Sea, but rises with a gentle acclivity or a considerable tract until it reaches the watershed between the rivers that flow eastward to the Red Sea, and those that run westward to the Abil. From the Lake Halik it runs into the sea, divided into a dextral and sinistral river, neither of which has a channel for the discharge of its waters. This tract is very unhealthy, and uninhabited. The country between this swampy country and the edge of the table-land is called Hamasien, and constitutes the most northern and the narrowest portion of Tigré.

Abyssinia may be considered as lying at the base of the table-land on the south. At the north the table-land is crossed by the road leading from Tadjourah to Ankōsar, its level is about 2200 feet above the sea. As its course is not rapid, it is probable that the swamps in which the Hawash originates are not more than 5000 feet above the sea. From the Hawash to the western coast of Abyssinia there are many watercourses. The narrowest of these, which is called the Great Hawash, is a very remarkable length in Abyssinia, since it rises above the Red Sea, and falls to the sea, as an ordinary river, without overflowing any considerable distance.
South of 15° N. lat., the hills which are on the edge of the table-land occupy a much greater extent in width, or rather they form two ranges, which enclose a longitudinal valley. The western range, which runs from north-west to south-east, may be called the Debra Dome range, from a similarity of its general form to the western recesses of this mountain and most inaccessible summits. This range does not appear to rise in general more than 500 feet above its eastern base, though a few summits may attain even 1000 feet, but it consists principally of the sandstone, and Antalo, which indicate that it is more the product of a series of long and rather steep descents by which it is entered from the south. This descent is known as the Pass of Atbara, and lies near 17° 8. lat. and 40° 25' E. long. The difference between the level of this pass and that of Antalo is probably more than 1000 feet, for Rüppel estimates the elevation of the summit of Kikirri, which lies on a hill of some elevation, at 6348 feet above the sea; and he observes that the Harramat Mountains are at least 1200 feet above the level of the plain. Fevers also observes that the natives, in ascending this Pass to say that they pass from the warm into the cold country. This plain, which, from the name of one of the provinces it contains, may be called the Plain of Temben, extends from the base of the Harramat Mountains to the Takkazie, from past by north to west by south, more than 60 miles, and continues along the northern banks of the river for at least 30 miles farther, so that the whole length is about 100 miles. It is narrower at the base of the mountains, and grows broader towards the north, and it is so at its highest, so that it may cover a surface of 3000 square miles. It occupies the whole space between the Pass of Atbara and the towns of Asum and Adowa. This large plain is in general not fertile. At the base of the Harramat Mountains is a tract of land which is entirely covered with sandstone; and nearly the whole of it is under cultivation. There is another rich agricultural tract near the heights over which the Pass of Atbara passes, where wheat and barley are extensively cultivated; and two or three small rivers, which can be irrigated; but these tracts are not extensive. The greater part of the plain consists of low sandstone hills, and the soil is sandy and unfit for cultivation. In other places there is clay slate, usually in perpendicular strata, and these strata are less well covered, and appear to rise and fall with the strata. Trees do not occur, and in most places only shrubs and bushes of stunted growth are found, among which the Ephorbia canariensis is common. In the middle of the plain there is an extensive annually which constitutes a fine pastoral country, and is interspersed with trees. Here and in some lower depressions cultivation is also carried on to some extent. The beds of the rivers, which generally contain water even in the dry season, are considerably depressed below the surface of the land, and even the bottoms are wooded, but these bottoms are very narrow. In approaching the river Takkazie the level of the plain lowers by steep and long descents, which constitute several terraces. These are particularly low at the village of Cali, situated near at the most southern part of the plain, Rüppel found the level of the Takkazie 3084 feet above the sea.

North of the Plain of Temben are those of Shiré and Serawé. They are more elevated than the first-mentioned plain, and at the base of the ascent by which they are reached are situated the towns of Asum and Adowa. The first place is 7092 feet and the second 6216 feet above the sea-level. Hence we may conclude that these portions are more than 9000 feet above the sea. The southern-western portion is called the Plain of Shiré, and the north-eastern that of Serawé; but we are not acquainted with the line which separates them from one another, nor with their extent to the north and west. The first appears to extend to the country of Bari, or Shangalla, and the last to the swampy region of Maleb. The Plain of Serawé is celebrated in Tigré for its flowery meadows, shady groves, and rich valleys. That portion of it however which was traversed by Rüppel, and which extends along the banks of the Takkazie, is not more than 10 miles long, and 20 miles wide. From the banks of the river, which is at Shalt 8775 feet above the sea-level, one long and steep ascent brings the traveller to the plain, whose surface is composed of sandstone, and on which a certain portion of the river bed rests. The country, consisting of the decomposed volcanic matter, is partly covered with low bushes, between which there is a fine turf that makes excellent pasture. In some places there are trees, and among these date-trees. One of the volcanic hills, called Alape, rises 200 feet above its base. The western portion of the
Plain of Serawé, or that which is contiguous to that of Shiré, does not differ much from it in aspect. On the plain, which is generally level, and consists of sandstone, several ridges of basaltic hills, and a few isolated cones composed of volcanic matter, give a small mountainous character to it, and render it slightly more interesting to the traveler than the country about. The greatest part of the plain is covered with bushes, between which there are excellent pasture-grounds. The hilly ground along the western coast is composed of bushes and the Euphorbia canariensis. The eastern part of the Plain of Serawé, or that which approaches the mountains with which the edge of the table-land of Tigré is crowned, is somewhat different from the interrupted plain which it replaces. The surface is either bare sandstone or a thin layer of poor soil. Between the table-lands are some valleys, from half a mile to a mile in width, which are partly used as pasture-grounds and partly cultivated.

The Plain of Serawé is separated from the Hararam Mountais by a hilly tract about 50 miles in length by 30 wide. At this tract constitutes the principal part of the province of Tigré, which has given its name to this great division of Abyssinia, it may be called the hilly region of Tigré. The rivers which originate in it run westward, and form by their union the Mareb. This tract presents a great variety of surface and productive powers. Hills and short ridges are numerous; but, except one or two, they are not of great height. Some of them are sparsely wooded by stunted trees, or covered by bushes, and are partly cultivated; but others are composed of sandstone or clay slate, and are nearly bare or only covered with low stunted bushes. Some of the plains extend over a mile in width and are in a state of high cultivation, whilst others suffer from want of water, and are not inhabited except in the rainy season. The valleys resemble the plains.

The southern part of Tigré, or that which is south of the Plain of Antialo, has a mountainous character. Our information respecting these countries however is scanty, as they have only been traversed by a few travellers in haste and under unfavourable circumstances. This part of Tigré comprises the extreme western end of the river Affaru-Abba, one of the affluents of the Tảkázii. Near the source of the Tazzii the watershed between the rivers which flow north and south, and at some distance from it, probably on the watershed, are two large lakes, of which the larger is called Tazdo Bala or, the great lake of Ashangi, and is three days' journey is circuit; the smaller is called Gual Ashangi or Machath. The country surrounding these lakes and the source of the Tazzii must have a great elevation above the sea-level. Peacock and vulture are in evidence in the beginning of October, and Kaffa reports this tract densely forested, with stunted trees, and with some grass, which also occurs in Shoá, but only at an elevation of from 8000 to 10,000 feet. Both travellers complain of the cold that they experienced. The country is a complete wilderness, and there is no use of any wild beast except the fox. It suffers extremely from want of water all the year round, and produces only, at a few places, kolqual (Euphorbia caudata) and thorny acacias. The numerous hills which are dispersed over it are composed of sand. To the east of this central table-land of Abyssinia extends a mountainous country, of which we have no information. It is inhabited by the Raia or Azabo Gallas, who are described as the most savage of all the tribes of Africa. It is certainly a remnant of the ancient Cynocephali of the Yeô and have not the intercourse with them, and were unable to give the least information about them and their country to Kipaf. To the east of the mountains inhabited by the Raia lies a country called Zoló; it is said to be a fine country, well wooded, and producing grapes, olives, limes, cedars, and other fruits and trees; but, in consequence of long wars, it is now uninhabited. It is said to have remained in this state since the time of Mohammed Gragne. In the south of Zoló, a faithful Kaffa, who was sent through Zohul to attack Adal, the soldiers dropped a quantity of durrah, which has since continued to grow without cultivation. Zoló is contiguous to Adal. (Adal, P. C. S.)

The country surrounding this mountainous country may be spoken of as the Tazzii low and its affluents are represented as resembling a sea agitated by a gale, rising in numerous hills like waves, with large spaces of lower ground between them. The hills as well as the depressions are covered with sand and almost without vegetation, except some kolgal-trees and thorny acacias. For the greater part of the year it is almost destitute of water, which is only found in wells, which are dry during the summer. In these wadies there are only a few pasture-grounds and cultivated spots. Dr. Béke is of opinion that this tract is not so high as the basin of the Takkazie, which is also a mountainous country. But this has no foundation. The basin of this plain is between 6500 and 7000 feet above the sea; but as in the northern part of Tigré, Lazia is considered a very cold country, it is probably higher than the Plain of Antialo, it is certainly uninhabited, and constitutes the natural boundary between Northern and Southern Tigré.

The Takkazie is the second river in Abyssinia in size, the Abâi, or Nile, being the first. It originates near 12° N. lat. and 39° E. long., and its upper course in Abyssinia is to the north, until having received the waters of the Tassar from the east, and those of the Béllega from the west, it turns by degrees to the south-west, and then to the south, and the south-eastern portion of the basin of the Nile, and all the volcanic matter brought down by their rapid currents is thus carried to the Nile. Rippeil, who has seen the greatest part of the course of the Nile, is decidedly of opinion that to this volcanic matter mainly, if not entirely, the great fertility of the soil is to be ascribed, the deposits in its lower course during the inundations. If we consider that the countries lower down on both sides of the river have either a sandy or rocky soil of very moderate fertility, and are frequently divided by a dividing ridge which appears to be well founded. The bottom of the Takkazie is very narrow compared with the size of the river, and there is frequently no bottom at all, the rocks rising immediately from the water's edge to a considerable height, and attaining at a distance of a few miles an elevation of from 2000 to 4000 feet above the river.

The western and southern part of the table-land of Abyssinia is called Amhara, from a province of that name situated near in the middle of it. The southwestern portion of this large country bears the name of Shoá. Under the name of Amhara we shall describe the country which is divided by the Takkazie from Tigré, and extends southward on both sides of Lake Tana or Zaâ to the most southern bend of the Nile. It is divided from the last-named river by the Abar leben a great river and a line beginning on its banks at a place called Broken Bridge and terminating at the source of the most southern affluent of the Takkazie.

The Table-land of Tigré contains the highest mountain-range in Abyssinia. This range in the most eastern portion of the country is close to the banks of the river Takkazie in the province of Samen or Simien, whence it is called the Mountains of Samen or Simien. This range begins in the south with Mafi Gagra, a mountain, which runs from north to south and lies near 12° 30' N. lat. and runs nearly due north to near 13° 30', so that in length it extends about 70 miles. The most elevated summits are towards the northern extremity of the range, where the peak called Abba Yaret rises to 10,000 feet and that which bears the name of Bâbâat to 14,364 feet above the sea-level. The two high summits are only a few miles distant from one another, Abba Yaret to the east and Bâbâat to the west. Their northern declivity is usually by a ridge, over which runs a mountain-pas called Sekli. This peak is 12,696 feet above the sea-level. Between the two
summits is a deep depression, in which a river, the Mashada, which rises on the ridge of the Selki pass, runs southward. Another river runs northward, the basin of the Best, and its highest point is only about 450 feet below the summit. Rippl found, in July, the upper part of the summit, to a distance of 1500 feet below the summit, covered with snow. This portion of the range is composed of plutonic rocks, lava, and basalt columns, and the bed of the Best, and the highest portion of the range and the river Takkazie is about 30 miles in width, and is covered with mountains, which grow lower as they approach the river. The greater number of attentions and studies of the more are the plain which are composed of lava. Near the river the sandstone is nearly bare, and only here and there covered with thorn-bushes, but in ascending the steep valleys the sides of the hills are clothed with trees or fine grass, and the bottoms are either meadows or fields in which barley is cultivated and yields good crops. Agriculture is favoured by the climate, which all the year round resembles the spring in Europe, by abundance of rain in every month of the year, and by the absence of locusts, which frequently lay waste the corn-fields in other parts of Abyssinia. In the higher region the mountains, up to the parts which are covered with snow, are pasture-ground equal to the famous Alpine pastures in Switzerland, and the scenery is also very similar, except that in these regions there is almost no cultivated plant is a palm, which resembles the palm: it is called gibara (Rhynchoscopatum montanum), and its peculiar shape makes a very pleasant impression on the observer, when it stands near tracts cultivated. Here are also seen, with the leopard and hyenas, two inhabitants of the European Alps, the mountain-goat (Capra ibex) and the lammergeier (Gypaetus barbatus).

The western declivity of the mountains of Semien is less broken, and terminates about ten miles from Mount Bushat at the Plain of Entetquab, which is about 10,000 feet above the level of the sea. This plain extends for seven miles westward, where it is interrupted by the valley of Shoda, which is at least 4000 feet below its surface, and is traversed by a river called Bellega. The plain has an undulating surface, and is entirely destitute of wood, except those clumps of trees which surround every church in Abyssinia. The soil however is good, the pastures abundant, and the barley yields rich crops. The whole plain is available for some of these purposes. Rippl passed the months of July, August, and September, 1852, in Entetquab, and observed the thermometer four times every day. The results of his observations are—

The temperature of Entetquab was therefore in July and August eight degrees lower than in London, but in September only a little less than two degrees. The weather was very foggy and rainy. The wind blew in the evening and mornings, from south-west, or south-west-south, and during the day from west-south-west, or from the plains.

The small table-land of Entetquab is separated from the large table-land of Woggghera by the Vale of Shoda, which is at least 4000 feet, as already observed, lower than Entetquab. It is from three to four miles wide at the top, and more than a mile wide at the bottom. The bottom is partly swampy, and only used as pasture-ground, but on the gentle ascent much barley and some fias are cultivated. The table-land of Woggghera extends 15 miles from south to north, and nearly as much from north to south. The greater part of it is about 8500 feet above the sea-level. Near the vale of Shoda its surface presents low hills and depressions; but farther on it is almost a dead level, with a few isolated hills dispersed over it. They are all of volcanic origin and of conical shapes. The highest of them, called Waaken, has only an elevation of about 800 feet above its base. There are many watercourses, but they are deeply depressed below the general level, and in summer they are totally dried up. As the body of the table-land are of volcanic origin, the soil is rather fertile, and produces good crops of barley, which however is only cultivated in a few places. The incessant civil wars from which this country has suffered for ages has driven away the husbandman, and his place is supplied by wandering herdsmen, who go with their herds and flocks during the dry season to the low country on the lake Zana. The pasture-grounds are very good: the descent from the table-land to Gondar and the country surrounding Lake Zana is gradual, and passes through several valleys, whose declivi-
great extent from east to west. Though only about 400 feet lower than the 5th mentioned pass north of Gondar, or 5000 feet above the sea-level. Its soil is somewhat swampy, partly covered with canes more than ten feet high and partly with fine trees. Several rivulets pass through it, though the flow is the head of the small lakes. This low country is uninhabited on account of the bad air. Through want of vegetation the vapours rising from the surface, which is covered with water during the rainy season, are less damp, so that it is inhabited by persons without contracting a malignant fever. It is the haunt of numerous wild animals of the largest size. Buffaloes (Boo caffer) and elephants are met with in herds and flocks.

There are also rhinoceroses with two horns, and various species of reptiles and doer of very large size, especially Antilope defassa, Rippel.

We come now to that depression of the table-land of Ambara, the lowest part of which is occupied by Lake Zano, called also the Lake of Dembas. The surface of the lake is 6110 feet above the sea-level, and from its shores a flat country extends on all sides to the high lands which surround it at different distances from the lake. From the mountains including the plain of the Upper Teke, there are several lower ridges run westward and approach the shores of the lake: the northern, on its north-eastern bay, opposite the island of Mraxa; and the southern, north and south of the efflux of the Abdi from the lake. These two offsets separate from the plain of Dembas, the eastern, western, and southern sides of the lake. These plains derive their names from the provinces in which they are situated. The northern is called the Plain of Dembas, the eastern the Plain of Dinka, and the western the Plain of Gondar. The Plain of Dinka, which is also called the Plain of Gondar, from the capital of Amhara, which is built on hilly ground at the north-eastern extremity of the plain, extends about 20 miles from north to south, and 40 from east to west. Its surface at Gondar is 7420 feet above the sea, so that its descent is rather rapid: for in 20 miles it sinks 1300 feet lower. Near the surrounding hills are numerous low volcanic hills, mostly overgrown with bushes; and in their vicinity the soil is fertile, and part of the country is under cultivation. At a distance of three or four miles from the heights the hills disappear, and are replaced by an undulating surface, whose soil, being composed of disintegrated volcanic matter, is a black mould of great fertility, but very little of it is under cultivation. There are no trees, except round the churches. Bushes are frequent, but occur only in patches. In the dry season, from October to April, the country is almost covered with herds of cattle, which, when the rains begin, enter the forest, and the intervening plain is then nearly converted into a swamp. Even in the dry season those tracts which are near the lake are marshy, and only inhabited by fishermen. The plain is drained by many small streams, the course of which is destroyed, and the exception of the largest, named the Aby, which passed six months and a half at Gondar, and made meteorological observations four times every day. The result of these observations follows:

It would be very interesting to compare those observations with those made at Mexico, especially as the difference of elevation is small, Mexico being 7476 feet and Gondar 7420 feet above the sea, but the difference of climate is less than seven degrees. Mexico being situated in 19° 26' and Gondar in 12° 36' N. lat. The meteorological observations however respecting Mexico, which have been published, do not hold over, but contain the months of January, February, and March, because the extreme season of climate had not been ascertained. For October it was 61° 52', for November 59° 52', for December 56° 56', and for April 57° 54'. From these data we may conclude that the temperature of Gondar is from two/thirds to two-thirds of that of Mexico, which appears to be more than could be expected from the difference in latitude. The annual quantity of rain at Gondar is very great, which is not generally the case on elevated table-lands and perhaps it is due to the circumference of the town being built in a wide depression of the table-land, and partly surrounded by heights which rise a thousand feet above its level. The annual quantity in 1770 was 35-5 inches, and in 1771 it was 41-9 inches. In January the height is nearly six inches; in February and March, in April and May there is more rain, but the rainy season properly commences in June and lasts to October. In July and August the rains are very heavy, and the height of the rain in a month sometimes attains a value in two months. In September the rains become moderate, and in October they cease, with the exception of a few short showers which fall in November and December. During the day from the morning from north-east, but it turns before nine o'clock to the east, and at noon it blows from the south-west. In the afternoon it turns to north-west, where it remains until it becomes calm after sunset.

The narrow strip of low country which lies west of Lake Zano is a part of the Plain of Dambas, and is included in the province of that name. The adjacent heights do not rise to a great elevation above the level of the lake. Their declivity is very slight, and their surface is covered with a fine soil, from which a considerable quantity of gum-arabic might be collected. At the base of these heights the country is fruitful, and a considerable portion of it is under cultivation; much durra is grown. This tract is considered one of the granaries of Gondar. In the south and west of it there is a tract of country, which is watered by the Abdi, and is covered, the whole being used as pasture-ground and meadows. The deep black soil is very favourable to vegetation, and is usually covered with high grass. Cattle are very numerous. In the north, the slopes of the low hills are covered with little terraces, which, with the exception of the great plain of Dambas, which have a sluggish current. The village of Dingelabar stands on a rock which forms the extremity of a ridge that projects from the heights on the west, and which the river runs through. In the south, there remains only a narrow place on its shores, through which the great road passes which leads from Gondar to Miecha and Gojum. The table-land which is west of the tract just now noticed is that of Kuasa and Ras-el-Feel, of which the first-named province forms the southern and Ras-el-Feel the northern part. Kuasa has never been visited by a European, but Bruce passed through Ras-el-Feel, which he describes as a fertile and level country with a rich black soil. The surrounding surface is mostly covered with marshy tracts, where the hay is cut in the spring, and spelt is grown. A grove of trees. Cattle and horses are numerous; but honey, horses, and gold, which is here found in larger quantities than in any other part of Abyssinia, are the principal articles which are sent from Ras-el-Feel to the other provinces and to Sennar.

The Plain of Bignemider, which lies on the eastern side of Lake Zano, extends from near Ethos on the north to the banks of the Abdi or Nile, nearly forty miles in length. Its width, from the low shores of the lake to the high mountains-masses which inclose the upper basin of the Takkazie on the west, is nearly thirty miles. The mountain-masses rise from the plain with a steep ascent, except where their edges are broken down by the torrents and rivers, which originate in the higher land and tumble in cascades to the lower plain. The elevation of these mountains of Bignemider is estimated by Dr. Beke at between 7000 and 8000 feet above the sea, and the last-mentioned elevation being assigned to the heights of Châmana Marigna. As the level of Lake Zano is 6110 feet above the sea, the mountains of Bignemider rise only from 1500 to 2000 feet above their bases, or rather less, as the plain has a gradual rise from the shores of the lake to the foot of the mountains. The western part of this region, called the Reb, where the plain is not so wide, consists of two tracts of different characters, a lower one skirting the shores of the lake for several miles, which in the rainy season is inundated and in the dry season covered with a sand or fine grained soil, and a more elevated part which has an undulating surface, and is covered with low bushes. No part of this district is under cultivation, but both supply pasture. On the declivity of the sandy country there are extensive orchards which produce fine grapes. From the river Reb to that of Fogata, and even farther to the south, the country is a dead level, and the soil
This consists of a fine black mould of great fertility, which is the deposit of the earthy matter brought down by the rivers Reb and Gumara. There are no springs, but good water may be found by digging to the depth of a few feet. There are also a few springs near the river-bed. Only a small portion of this fine tract is at present cultivated; but the numerous traces of the canals for irrigation show that formerly it was a corn country, which has been reduced to its present low state by the want of water. Numerous herds of cattle find pasture during the dry season, but when the rains have converted the whole into a swamp, the cattle are taken to the high land on the east. Near the banks of the rivers are extensive fields, in which lupines and vetches are cultivated. The river canals in the plains have been raised more than five feet below the level of the plain. This country is better peopled than the adjacent provinces of Abyssinia. The most southern district of the plain of Bonga, or that belt of land between the Abai (Nile), at its efflux from Lake Zana, has a very broken surface, being traversed by several ridges of rocky hills which detach themselves from Mount Chamma Manfarga, and run westward to the lake and south-westward to the Abai. These ridges are covered with fine forest-trees, and as the depressions are extensive and wide and watered and have a fertile soil, cultivation is carried on to a great extent. As in approaching the banks of the Abai the country becomes more broken and the ground rises higher; and though only five miles from the river, is at least a thousand feet above its level at the bridge which is here thrown over the Abai. The hills which skirt the banks of the river are composed of volcanic rocks, and show great fertility in the vicinity of the Abai, which is three times as wide as the Tana. The lake is covered. From the efflux of the Abai from Lake Zana to the vicinity of the cataract of Alasa, the river runs through a wide bottom which is covered with the finest grass.

The Plain of Mischka is a part of the Peninsula of the Abai. This peninsula forms a part of Amhara, but as it is naturally separated from the other divisions of the country, and constitutes by itself a well defined system, it ought to be noticed here. The river Abai extends from the lake, on the north, west, and south, and its western limits may be tolerably well defined by a line drawn from the banks of the Abai where it is joined by the Jamna to the village of Dingolbor on the shores of Lake Zana. Thus limited, the peninsula extends from east-south-east to west-north-west 150 miles, with an average width of about 100 miles, so that it covers an area of 15,000 square miles, or more than half of Ireland.

This great branch of the Nile is uniformly called by the inhabitants of Abyssinia, rises near 11° N. lat. and 37° E. long., at the foot of Mount Gish, in a swampy tract. The source of the river is 8700 feet above the sea level, and the summit of Mount Gish about 9700 feet. After running about 20 miles, or about 60 miles from the Abai descends from 8700 feet to the level of Lake Zana (6111 feet), or about 2500 feet, or more than 43 feet a mile; the current is of course extremely swift, and forms a kind of continuous cascade, as the falls are innumerable. This has been visited by Bruce, who found its perpendicular height 16 feet, and he heard of another. The Abai enters Lake Zana on the south-west side and leaves it on the south-east side. Accordingly to Bruce this lake is 56 miles broad in the widest part, from east to west, but it decreases in width towards the extremities, where it is sometimes not above 10 miles wide.

Its greatest length, according to the same authority, is 94 miles. Bruce and Rüppel, the two travellers who have had an opportunity of viewing this lake in the same shape on their maps. That on the map of Rüppel is much more regular. The number of rivers which the lake receives from all sides is very great, those which join it from the north and west are dry during a great part of the year, but that from the east contains water all the year round. The immense supply of water which the lake receives during the rains, raises its level sufficiently to lay under water the low country on its banks to the distance of two miles. There are many islands in this lake; Rüppel has laid down eighteen in his map. The greater number of them are inhabited. The largest, called Dock, is low, but of considerable size. To the east of it is the lake of the same name, which is a continuation of the one. Fish is abundant and of various kinds, most of which are of the family of the Cyprinidae, and are taken in great quantity. The hippopotamus is common in the lake, but the crocodile is not found there. The Abai river leaves Lake Zana north of its south-eastern corner, and after running south-east for about 15 miles it forms the cataract of Alasa or Tis Eset, where the river descends about 100 feet perpendicularly. Below the cataract, the river is constricted, and leaves a great flat rock, which at one place is hardly more than two yards wide. We may form a notion of the rapidity of this part of the Abai, from the fact that at the Broken Bridge, which is about 40 miles from the mouth, the current sends down in two hours more than 3852 feet above the sea. In 40 miles therefore the river has fallen 2259 feet, or about 66 feet per mile. From the Broken Bridge the current abates. North of the Mietta Ford, which is north of the place where the Abai is joined by the Abab, and which is one of the most severe on the river, the river is still 2936 feet above the sea. In this space therefore the Abai has fallen not much more than nine feet per mile. At the Mietta Ford the river begins to turn westward, and by degrees numerous gibbous spurs of the central Kilimandzaro. From forth, 60 miles lower down, the elevation of the Abai above the sea-level is 2815 feet. In 60 miles therefore it has fallen 111 feet, or not quite two feet per mile. Where the Abai leaves Abyssinia it is joined by the river Durm.

The interior of the peninsula of the Abai is traversed by a mountain-range whose general direction is from west-north-west to east-south-east. It may be called the Talha Waha mountains, though that name is properly applied only to the section of the range from the most westerly point of the Abai to the 37° 50' E. long. This range begins on the western border of Abyssinia with Mount Esbit, and runs eastward to Mount Bari, Mount Atazab, and Mount Gisch, where the sources of the Abai are. Mount Gisch, as already observed, rises to 7700 feet above the sea, and is the highest of the eastern group. Mount Lichema, which is still higher. East of Mount Lichema there is a depression in the range of a considerable extent, but then the range attains its greatest elevation, as it is supposed, for the elevation of no part has been accurately measured or in any other way. This portion is called Talha Waha. Where it begins to decrease in elevation east of 37° 50' it is crossed by the great commercial road leading across Mount Yakan. North of this the Abai descends from 7700 to 4575 feet, and is therefore no longer a mountain pass through which the road runs is about 11,000 feet above the sea-level; and Mount Geola, which is near and on the northern side of the range, is 8751 feet high. East of the mountain-pass just mentioned, the range subsides and has only a moderate elevation above the general level of the country; at the same time it changes its direction, and runs to the north-east. As it approaches the banks of the Abai it rises again to a considerable elevation in the mountain mass of Mount Yakan. A considerable portion of this range may be included in the system of the Talha Waha mountains. It does not appear that any summit of this range is always covered with snow, but the higher portion is cold from November to March. This range is in general covered with forests of large trees, but there are also a number of extensive fields or agricultural grains that are cultivated in Europe. The higher region is dotted with heaths and fenns, and the most elevated is an extensive level producing stunted grass, interspersed with numerous small river beds. One of these is the base of the Talha Waha mountains lie the Plains of Mischka and Gojam. The first extends northwards from their base to the shores of Lake Zana and the Plain of Gojam from their southern foot to the banks of the Abai. The descent towards the lake terminates at 611 feet above the sea-level, but that towards the Abai at 2815 feet, this being the elevation of the river at Melka Kuki.

The country which extends from the northern base of the Talha Waha mountains, and extends to the range of the Abai, is the district of Mischka (Maisha, Matche), from a province of that name, but this name properly applies only to the low country which extends from the Pass of Dingolbor along the south-western shore of the lake to its most-southern corner. Between these two districts is a plain of about 20 miles in extent, and which when the Abai river it is 20 miles wide, extending from the lake to the confluence of the Abai and of the Kelti. A line drawn from this point to the village of Karaguna, on the river of that name, which is about 50 miles distant, appears to indicate the low plain of Mischka from the hilly tract that lies south of it and extends to the base of the Talha Waha range. This plain is very fruitful, the soil being an alluvium composed of
the 'detritus' brought by the rivers from the higher country, but as it is entirely flat, it is not well drained; the currents of the rivers are stagnant at the close of the dry season, especially in January and February, and many pools are left by the inundations. This renders the country unhealthy; as bowels distemper and small pox are prevalent, and there is now no cultivation. Almost everything is well cultivated, and produces abundant crops of every kind of grain. A narrow tract near the lake is too swampy for cultivation, and is partly used as pasture-ground, but the greater part is covered by bushes, especially a large kind of rushes, which are for want of wood are used for the construction of small boats by which the lake is navigated. There are no trees or bushes on the plain, except near the base of the more elevated tract south of it, where there are some low stands of Johnson grass. The banks of the rivers are usually more than 25 miles in width along the banks of the Abdi to its confluence with the river Jamma. Its surface is diversified with several low and rocky ridges, between which are small plains. The courses of the rivers, which are rather rapid, show that the descent of this tract is considerable, and this prevents stagnation, and renders the country healthy. The soil is chiefly composed of decomposed volcanic matter, and is fertile. Those tracts which are not cultivated are generally covered with woods of acacia, which attain a considerable size, and those tracts which are destitute of trees and bushes are overgrown with wild oats and wild lupines. This tract contains abundance of water, and is very healthy. Between it and the mountain range of Abyssinia lie two churches, which may be owed to Lijamberra and Amidambit, rise to a great elevation, but between these and other ridges are many tracts of more level ground, which are partly cultivated notwithstanding the gullies and beds of torrents which intersect it and sink deep below the surface. The northern slope is generally gentle and the mountains are covered with berbega and acacias, and higher up are forests of different kinds of trees. The pastures on these mountains are excellent. Even in the vicinity of the source of the Abdi large quantities of barley are raised. Along the eastern bank of the Abdi is a marshy plain, several miles in length and bounded by high hills, which is partly used as pasture-ground. The eastern part of the Plain of Mileasa, or that which borders on the banks of the Abdi below its efflux from the Lake, is covered with a rich growth of melia, which has a somewhat different character. Its general level is much higher than the low part of the plain before mentioned, but it is tolerably even, except that it is furrowed by numerous deep valleys, in which the watercourses lie; towards the Abdi its descent is generally steep and difficult. The soil of the level grounds is of moderate fertility, and partly cultivated and partly used as pasture-ground.

The Plain of Gojam is surrounded by the Abdi in the form of a crescent, and the east begins at Mount Yekandach, and terminates on the west at the mouth of the river Zingini. The middle region is a table-land from 2000 to 3000 feet above the level of the river. This table-land is also a marshy plain, and the continuation of the broken country which lies between the plain and the river. Between the plain and the highest part of the Talba Waha Mountains is a mountaneous tract somewhat less than 20 miles in width. Thus the average width of the whole region is about 60 miles. The ascent from the river from the Ford of Miotta (some miles north of the mouth of the Jamma) is formed by a succession of bluffs which rise in terraces. Near the river the whole is thickly covered with jungle, and no part of it attains a considerable size; but higher up the jungle is less dense, and occasionally intermixed with cultivation. Towards the level country the ascent is more regular, the country rising with a slight and continual slope. Here the jungle alternates with grassy tracts, but even here cultivation is rare. The watercourses run in beds deeply depressed below the surface, and with great rapidity. The ascent from the south from the ford called Melka Kuki and Melka Furi is more irregular and steep. About seven or eight miles north of the ford, the river has a large and almost perpendicular wall, which in the lowest part is from 500 to 800 feet high, but in some places crowned with peaks that rise several hundred feet higher. Between this wall and the river, but nearer the river, is another terrace, whose descent is very steep. It is formed by the river, which from the higher terrace occasionally advance nearer to the river, where they appear like bills. The banks of the river are rocky and precipitous. Above the highest of the terraces is a level tract several miles in extent, which rises regularly but slowly to the north. This tract contains the large towns of Yejidjib and Yaush, and the market-town of Bado; and the country is almost entirely under tillage, except towards the north, where it approaches the last steppe or terrace, and is there used as pasture-ground. The last steppe, which is more than 20 miles from the river, is formed by a slope of moderate acclivity, and reaches an elevation of about 2000 feet. This extremity of this region is the ford called Melka Abro, and the ascent occupies only about 12 miles in width, and is more moderate as it rises gradually and is only interrupted by solitary hills. On this slope the country is cultivated, but only to a small extent. All the watercourses that traverse these ascents run in very deep beds, and the sides of the heights which border them are clothed with jungle or trees. The table-land continues across the south-eastern part of the western districts. The eastern district is the plain of Gojam and the western that of Danom. The Plain of Gojam extends westward to the banks of the river Godibe, an affluent of the Bir, and comprehends somewhat more than one-half of the table-land. Towards the mountains of Talba Waha it is almost a perfect level, through which the rivers run with a sluggish current; but while where it approaches the descent to the Abdi the rivers sink much deeper below the general level of the country, the current is quick, and at some places interrupted by rapids and cataracts. In these parts there are also a few hills on the high grounds between the watercourses. No trees are found in this plain, except the plantations round the encampments which are sometimes clothed with shrubs covered with grass, and are very little cultivated and inhabited; but where the ground is somewhat broken, cultivation is carried on to a greater extent. The Plain of Danom, between the river Godibe and the Zingini, rises and sinks alternately with the surrounding ridge on which it is situated. This is a perfect level, overgrown with gigantic grass: as we approach the descent to the Abdi, it exhibits some signs of cultivation. In some places the grassy plain is interspersed with swamps. It is stated that this part of the plain could be cultivated with advantage, but for the frequent inroads of the Galla tribes which inhabit the southern banks of the Abdi.

The country which extends from the bank of the Zingini to the western boundary of Abyssinia, may be called the Volcanic Region of Abyssinia. The name derives from the fact, that it is connected by continuous chains of volcanic rocks and extinct volcanos. The name is also derived from a nation, the Agos, who differ from the other inhabitants of the country. The river Zingini runs in a bed of volcanic rocks, and the adjacent country exhibits unconvoluted signs of volcanic action. The surface is generally formed by the disintegration of volcanic rocks, which in some places protrude through it. The surface is much broken. Such is the country between the river Zingini and a continuous ridge of high hills which, on the north, is connected with the western and lower continuation of the Talba Waha Mountains at Mount Barf, and thence runs in a south-west direction towards the banks of the Abdi. This ridge consists of a mass of volcanic cones or high-pointed domes; the Peak Fut, which stands nearly in the middle of them, rises to a considerable elevation above its base. From the west of this elevated mass several lower ridges run off to the westward to the distance of several miles, when they terminate with bluffs in the adjacent plain. This tract has a heavy argillaceous soil, which is cultivated, and by means of irrigation yields abundant crops. In some places the volcanic rocks peep through the soil. The plain, which extends farther westward, is of indifferent quality, and chiefly covered with brushwood, with here and there some patches of open grassland, which originate at the foot of the volcanic ridge run westward and fall into the Durra, an affluent of the Abdi, which constitutes the boundary-line between Abyssinia and the country of the Shangallas, a tribe of negroes. Where this volcanic ridge approaches to the Talba Waha Mountains it is less fertile, though there are some fine plains between the high hills and mountains, which are largely cultivated, and covered with numerous villages: there are other tracts which are only used as pasture-ground, but they are covered with excellent grass, and filled with herds of cattle.
Dr. Besse, who in 1841 and 1842 passed a whole year in the region, gives an account of the seasons. The rains are more heavy and continual in the peninsula of the Abdi than in the Plain of Gondar. It was only during the month of January that no rain fell. In February slight rains only were experienced on ten days, and in March on nine days. In April the weather became more regular, and the rainy season commenced in June. Rain fell more or less every day, with the exception of five days, and continued through July and August. On the 11th of July the Abdi had risen so much as to be no longer passable. The rains continued to be heavy till the 19th of September, and then began to decline, this being the end of night and sometimes in the day. Heavy rains were experienced up to the 7th of October, when for the first time none fell. It was stated that the rainy season had commenced sooner and continued longer than usual. So, notwithstanding this duration of the rain, the rivers had fallen considerably, and in the middle of September the Abdi was crossed by the Gallas, who brought cloth and cotton to Basso market. The rain fell for several days in October, but in November it fell only on six days, and slightly. In the beginning of December only showers were experienced, but after the middle of that month heavy rains fell on several days.

4. Shoa, as a political division, extends only over the southern part of Abyssinia. It is bounded on the north by the tributary of the Hawash, which divides it from the independent Galla tribes, to the Berko, which falls into the Hawash (near 12° N. lat.), and the Wanchet, an affluent of the Jamma, which joins the Abdi near the town of Takkazie. To the south it is bordered by the Takkazie and the central table-land of Wolfa, though they are in possession of independent tribes. The Jamma is the largest tributary which the Abdi receives on the table-land of Abyssinia. It drains a great extent of country, which extends to the eastern edge of the table-land, and brings a great volume of water to the Abdi. Where it falls into this river its surface is less than 3000 feet above the sea-level. From this place the country descends to the south to the extent that it attains an elevation of between 5000 and 10,000 feet above the sea. On the south the table-land slopes gradually down to the wide plain, which is drained by the Hawash river. But on the east, at the upper branches of the Jamma, it descends with a steep declivity, similar to that with which the table-land of Tigre terminates towards the Red Sea at the back of the harbour of Massawa and Annesley Bay.

The valley of the Jamma appears to be enclosed on the north as well as on the south by high mountains, which rise from 4000 to 5000 feet above its level. These heights however are only the bluffs with which the table-land of Shoa terminates on both sides. The ascent is steep, but there is uncommonly little difference between them. These two terraces on the southern side of the river has a slight slope towards the river, and is generally fertile, and studded with numerous villages which contain a considerable population. The number of rivers which join the Jamma from the south is very great. Though their course towards the interior of the table-land is not rapid, they run with great velocity as they approach its northern edge, and most of them fall precipitously several hundred feet into a ravine, in which they continue to flow till they reach the sea. Thus the rivers are cut by narrow valleys into a great number of comparatively narrow ridges, which give it the appearance of a very mountainous country. This is particularly the case in the western district, where the extent of the villages and of agriculture is not diminished by the account of the Abdi, where the affluents join the principal river at right angles. Towards the eastern edge of the table-land they run nearly parallel to one another, and here the ridges between the valleys are more extensive, at least when compared with the sides of the narrower rivers. These ridges are generally level at the top, except towards their termination between the two rivers, where they approach their junction, and in these parts they gradually grow lower. Though the soil is chiefly rocky, it is of good quality, and produces pulao, tobacco, cotton, maize, and other grains. There are trees about the numerous villages. There are other tracts which are without villages or trees, but they supply pasture to numerous herds of cattle, except towards the west, where the country is overgrown with jungle; some tracts produce only shews and stunted acacias. The steep sides of the valleys are usually covered with jungle, and the banks of the Jamma the table-land takes that form which is expressed by this term. There are a few hills dispersed over it, but in general it stretches away to the water-bed between the Hawash and the Jamma either in a level plain or with an insignificant declivity, which is intersected by several isolated high hills and short ridges again make their appearance, but they do not rise to a great elevation, except the Garra Gorpha ridge and Mount Fintini. But towards the country on the south and south-east the table-land of the Jamma the country is more broken. The greater part of the eastern district of the table-land is destitute of trees and bushes. Some tracts are partly cultivated and partly used as pasture-ground, but others are entirely left to the herds and tribes to graze on. There are several large tribes which have strongholds or enclosures in the table-lands, which are surrounded by their own tracts of land.

The river itself has a length of 2200 miles, and is generally about 30 feet across. It ascends the Drava to the source, and then descends to the river of the same name, which it joins near the town of Takkazie. It then descends towards the sea, and in the course of the year it is fed by the rains, which fall in July and August, and from the rains the country is well watered, and the rivers flow all the year round. These districts are covered alternately with forests of high trees and by grassy plains without bushes. In approaching the sources of the Hawash the whole country is almost one forest, the haunt of elephants and buffaloes.

Our information respecting the southern declivity of the table-land of Southern Shoa is very scanty. But it is known that near the watershed between the Jamma and the Hawash rivers it descends with a gentle slope resembling a slightly rounded hill, with the usual declivity of between 800 and 1000 feet, and the streams in these parts are generally fed by rains only. These rivers descend steeply and furiously till they meet the Hawash stream. But the banks of the Hawash a steep descent may exist, when it is considered that the river at Melka Kuya, where it is traversed by the caravans and mountains, is about 2000 feet above the sea-level, and the current to the sea, and possibly even to 5000 to 6000 feet below that point, or one westward. There are a few high hills or mountains dispersed over the coast, which in the most elevated are Mount Enloto, Mount Sekuia, and Mount Ferrer. Considerable tracts are well cultivated and cultivated with villages, but more detailed information is still wanting, as this part of the table-land has hardly been seen by Europeans. We do not even know if the mountains which extend southward from Ankobar into the province of Bulga constitute only the edge of the table-land, or are a range which on both shores, or one westward, is bounded by a low country along its base. The course of the rivers favour the first supposition.

The eastern edge of the table-land of Shoa, from the town of Ankobar northward to the coast, is about 45 miles wide; it rises with a steep ascent from the low country west of the Hawash river, which is only about 2000 feet above the sea-level, to an elevation of from 8000 to 9000 feet. The ascent is so steep that a happy man must climb ten miles in width; to the west of it the country continues for a considerable distance at the same elevation. The town of Angollala, which is several miles from the edge, is 8564 feet above the sea-level, and surrounded by a plain intersected by several streams. The town of Melka Kuya and Ankobar, which on the straight line is about 30 miles. In the first ten miles from the river the country contains several plains of moderate extent, divided from one another by low hills; the level tracts are generally destitute of grass and water, and the higher parts clothed with jungle, in which sheep and goats find pasture. At Atkonti the country begins to rise, but in the next ten miles it hardly attains an elevation of more than 3000 feet above the sea. These tracts are thickly wooded, and between the two towns the savanna also completely covers the ground. The lower tracts between the hills are cultivated to a small extent. In the last ten miles the country rises to more than 9000 feet above the sea, the town of Ankobar is 400 feet above it; or about 700 feet higher than the city of Mexico, which is 7468 feet above the sea; but Ankobar is on the declivity, and the table-land is 400 feet above it. This steeper part of the ascent consists of a succession of hills and steep hills, which in the dry season are covered with snow. The soil must be rich considering the vigorous vegetation which it shows. The villages are small, but numerous; they consist of a few houses, which have a circular form, with a coral roof, and are produced with little difficulty.

In proceeding northward along the ascent, it preserves the same features, except that from time to time a valley is met with of moderate width, and of superior fertility to the adjacent tracts. There are also extensive tracts which are more wastes; they are generally more level than the other parts of
The ascent, and covered with bushes and herbaceous plants or woods of acacia; in some places there are forests of acacias, kokoulos, and euphorbias. Where these level tracts are at a considerable elevation, or where the soil is stony, in the ascent, they suffer from want of water; and where they are much lower, they are intersected by numerous water-courses and interspersed with swamp. The edge of the table-land is stony and cobbled. It lies almost flat, the depressions the ground is swampy or springy, and here are the sources of the rivers which descend to the east and west. In many places this edge is much higher than the town of Ankobar. It is preceded by the difference in the degree of vegetation, and by the vegetation itself. The southern end of the table-land, opposite to the rock of Massia, consists only of fire, heath, and fern. Some high mountains rise above the ascent, among which Mount Emnuren, a few miles north-north-east of Ankobar, rises to a considerable elevation, but probably not above the general mean level of the table-land, which is about 11,000 feet above the sea-level.

It is not known how far this steep ascent of the table-land continues to the north. It certainly extends from Ankobar to Kok Fare, a distance of about 50 miles, and probably to Antiockia. 35 miles farther, but in the parallel of Lake Haik (10° 22' N. lat.) it appears that the country lowers on both sides of the watershed by a long and gentle slope. Krapf, who passed over this country, does not speak of any difficulties encountered. The watershed lies on the table-land, and that the descent from it is at a considerable distance from it farther to the east; for Krapf expressly states that the climate grew much warmer as he proceeded northward. But he found that several lofty isolated mountains were observed on or near the watershed, among which Mount Sakio rises above the rest.

The country which lies contiguous to the steep ascent of the table-land (from 9° 30' to 11° N. lat.) on the west continues for a short distance to preserve the elevation of the edge, and then slopes gently to the west. The surface is generally level, forming plains interspersed with small hills or short low ridges; these plains however rise in elevation as they proceed northward, and as they approach Antiockia their surface is rather hilly than undulating. The most remarkable feature of this Northern table-land of Shoa is the deep depressions in which the rivers run; for a distance of several miles from the watershed they run in deep valleys, but farther on they fall down in cataracts several hundred feet high into deep basins, and below these basins they continue to flow between steeper and loftier banks; the descent to them is frequently 500 or even 1000 feet. The valley through which the Kachena, an affluent of the Wanchit, runs, is 3000 feet below the upper edge of its banks and the general level of the country, according to the estimate of Krapf. How far this peculiarity of the river-valleys continues westward is not known, although the country to the banks of the Abdi river, which is about 80 miles above the town of Abdi, has never been visited by any European; but as the country near the banks of the Abdi is also several thousand feet above its bed, it is probable that these deep valleys continue through the whole extent of it. Its surface is in the main very well wooded; but the table-lands between them are destitute of trees and bushes, and are only used as pasture-ground, though they have a deep black soil of great fertility, which is proved by the abundant crops which are obtained from the fields at the base and on the declivities of the small hills which occur everywhere, and in some places in considerable numbers. The grains and pulse which are principally cultivated are wheat, barley, pea, and hogs' beans. Cotton, maize, and rice are also grown. The water is very scarce, being in the main supplied by a few springs and shallow wells, which prove the great elevation of this part of the table-land. No domestic animals are so well suited to this country as a kind of black sheep, of which there are numerous flocks.

North of 11° N. lat. the table-land, as already observed, slopes down to the east and west. The scanty information which we possess about this country is not sufficient to give us a general idea of its character. It was traversed by Krapf in the early part of May, who states that the whole country informs us that several high mountains rise on the watershed, but where he crossed it there were two valleys separated at their upper extremities by a ridge of no great elevation. The western valley, called Tobola, from a celebrated market-place there, is intersected by the river Gheredo, an affluent of the Bashi, and on both sides enclosed by a range of hills partly covered with juniper-trees. On these hills there are many hamlets and villages. The valley is wide and well cul-
the greater part of their course in valleys many hundred and even thousand feet below the general level of the country: others are not much depressed in the interior of the high parts of the country, and in the middle of some large rivers they begin to sink deeper: and where they leave it their level is many hundred feet below the contiguous plains. It is probable, from the formation of the valleys, that the waters themselves have scooped out these deep and narrow depressions. We find in other and smaller valleys of the plains the same phenomenon in their quick rise and fall. After a heavy fall of rain the Tatkazie rises five feet in one hour; and when the rains continue, it rises to 20 feet above its common level. But in one or two days the water has run off, and the river fallen to its common level. In June, 1849, the Abdi suddenly rose three feet, in consequence of a violent storm which had happened the previous night; but the following day it fell again to its level. When travellers come to a large river, and find that it has risen so as to be unfearable, they are sometimes puzzled by this circumstance, and are afraid to wait twenty-four hours, or a little longer, when it becomes again fordable. The Abdi is passed at two places by bridges, but there are no other bridges in the country.

The Abyssinian climate varies between the tropics, its productions rather resemble those of the temperate zone, to which its climate, with the exception of the rainy season, bears a great resemblance, on account of the elevation above the sea-level. This is especially the case with the vegetable products. None of the grains of India are found here, with the exception of the negu (Sesamum orientale), a small grain which resembles the raggy of the table-land of Dekkan; but it is scarce. The other grains are wheat and barley, the latter grown most extensively, as it is the only corn given to horses and mules: oats are not cultivated, though large tracts in the Plain of Miécha are covered with wild oats. Indian-corn is grown in many places, especially on the lower parts of the table-land, as in the Plain of Gondar and in the country of the Yejoos; and in some places derrha (Holcus sorghum) and tobutsu, a kind of Eleusine. From this grain two crops are annually obtained as a general rule, especially where the fields can be irrigated. The leguminous vegetables which are most extensively grown are the French beans, the broad and the black leopards, and the skin of which fetches a high price in the country, and is worn by the governors of provinces. There are also lycias, liones, cats, leopard-cats, and the wild cats. There are also hyenas (Herpestes), a species of small cats, and the sable, a species of fox on the table-land of Wofla, and the jacks.

The larger quadrupeds are only found in the wildernesses which lie along the northern and southern boundary of the country. Elephants and buffaloes are very numerous; the two-horned rhinoceros is not so common; and giraffes appear only along the northern border. Shelducks and white pelicans are very numerous on the lakes. There is only one species of antelopes, among which the most abundant is the antelope saltana, the smallest of the horned animals, not larger than an English hare, and the Antilope Summerringii. Two species of hares and several kinds of small animals are common in some of the woods. There are various kinds of quadrupeds, as Cynocephalus baphusus, the Cynocephalus boni, and the Conus Ducoen, Rippet. Of smaller animals there are porcupines, rock-rabbits, ground-squirrels, and weasels, polecats, and beavers.

Fowls are generally kept. There are several species of eagles, the Gypaetus barbatus, and also several kinds of vultures. On the high mountains of Semien are Alpine ravens (Pyrrhocorax graculus). Rippet unites three kinds of parrots, Picaeetus Levallianti, P. Taranta, and P. Meyeri. In Tigré there are herons and hawks. The Egyptian goose and a species of duck, with several other kinds of water-fowl, frequent the swamps and lakes. Guinean-fowls, red-legged partridges, and pheasants are seen in many places, and are raised in the country; among the latter is the Colubma Abyssinica, whose beautiful yellow colour shades off into purple. There is also a beautiful species of muselaps. Horses are reared in the large rivers, where many are killed annually for their flesh and hides. Crocodiles are probably not found in the waters of Abyssinia. Bees are so common that honey is very abundant, and this prevents the importation of sugar. Locusts frequently lay waste the fields, and they are most frequently seen on the table-land of Tigré; other parts of the country do not seem to suffer much from them.

Abyssinia is poor in minerals. Gold has occasionally been found. There is a crop of a grain called woss (Dactyliosperma), which is worked, and appears to be of good quality. The great salt plain which lies between the Red Sea and the table-land of Tigré belongs partly to the sovereignity of Tigré, and immense quantities of rock-salt are annually taken from it and imported to all parts of the country, as it is not only used for culinary purposes, but also as currency. (Adal, F. C. S.) Large quantities of salt, taken from the salt lake Assal, are annually imported from Shoa, as salt is not found on the table-land. Sulphur is worked at Assir (Pop. and Inhabitants.)—Rippet estimates the area of Abyssinia, exclusive of the countries which form the kingdom of Shoa, at about 270,000 square miles, or more than double the area of the British Islands, and assigns to Tigré half a million of inhabitants. The population of this country, however, extends far beyond the Wollo Ghallas and the Yejoos, a million of inhabitants. But this estimate is certainly underrated. He had not an opportunity of seeing the best cultivated and most populous part of Tigré, the Plain of Antelo, nor the most densely peopled portion of Amhara, namely, the peninsula which is surrounded by the Abdi. Looking at the accounts of Dr. Beke, who traversed the last-named country repeatedly and in almost every direction, one would suppose that this part of Amhara alone must contain at least a million of inhabitants. The countries which at present constitute the kingdom of Shoa have an area of about 12,000 square miles. They are tolerably well peopled, owing to the peaceful state in which they live, and a well governed country. They are neither more nor less than those of Europeans, their eyes are lively, their teeth well set, and their black hair is either smooth or slightly curled. They are of a middling stature. They inhabit almost exclusively the high table-land, and are to be found in Amhara, Tigre, and in the south of the western districts of Shoa. The Fali, Jews, Christians, and Agows belong to this race, notwithstanding the different dialects which they speak. An-
other race is found mingled with them: it is more closely allied to the inhabitants of the interior of Afrixa, and is distinguished by a somewhat curved but not pointed nose, thick lips, and lengthened eyes, which are not lively, and by black but curly, and somewhat lost as a whole body. 

They are most numerous in the northern districts of Tigré, especially in Hamazien and the adjacent countries. The third race are the Gallas. Their face is round, their nose straight and short, but not pointed, and divided from the mouth by a deep furrow. Their eyes are very thick, but do not resemble those of the negroes. They have small eyes, which are very lively, but deeply set in the sockets, and their body is rather stout and large. These Gallas constitute the greatest part of the two eight population of Shoah, and the countries west of the Lake Zana and the river Abdi; they are also numerous in the armies of the other divisions of the country. There are no negroes in Abyssinia, except the slaves which are brought from the countries of the Shanggall, who inhabit the border countries to the west of the peninsula of the Abdi. These negroes are the only blacks in the country. The colour of the other inhabitants varies from the darkest black-brown to the clearest light brown, and does not appear to be peculiar to any of the races.

The Abyssinians have a dead language, the Geez or Ethio-
pian language. [ETHIOPIAN LANGUAGES, F.C.] The spoken languages are derived from it, and constitute, as it appears, four dialects, namely, the languages of Amhara, Tigré, Shoah, and Galla. All are written in a alphabet called Amharic, and differ considerably from one another; but the people understand one another and do not need an interpreter. The language of Gondar is considered to be the purest; it is also more rapidly different, and is spoken by the northern Gallas, who inhabit the elevated region which extends from the river Wasshilt, an affluent of the Jamma, on the south, to the Bashele river and farther on the north, and by the southern Gallas, who live on the highest part of the southern table-land of Shoah and other plains contiguous to the Hawsh river. There are also three other languages spoken in Abyssinia, which however are limited to a small number of people. There are two tribes called Falasha and by the Gomant, two tribes inhabiting the Semien mountains and the hilly country west of the table-land of Shoah, and the plains contiguous from the Amhara and Galla languages, according to the statement of Bünjel. He adds to these languages that of the Shanggall Takkaze, who inhabit the wilderness north of Shiré and Waldaqba, and who according to his statement are not the proper language by which is spoken the second race noticed above. But the Shanggalls, who live along the western border of Agoumarid, are true negroes, and speak a different language.

The Abyssinians are Christians, but their tenets differ materially from those of the Roman and Greek churches, so that their religion must be set down as the fourth great section of the Christian community. They are called Coptic Christians, and the heads of their churches, named Abuna, are ordained and set out by the archbishop of Alexandria. Respecting their rites and manners see P.C. vol. i. p. 57 and 58.

A great number of the Gallas, as well along the Wollo as among the southern tribes as far as they are subject to the king of Abdi, are called Wawi, and it appears that in part of Abyssinia there are many Mohammedians. They are numerous among the Yipioos and Wollo Gallas, and their number is on the increase. The Falasah in the Semien Mountains live in the Simen Dors, of which the Simen Mountains and the Simen table-land of Woggabores are a set of hewre, who have adopted a few ceremonies of the Christian community. Many Falasahs are settled at Gondar, where they inhabit a separate quarter of the town called Falashabad. The Gallas who inhabit the banks of the Hawsh are called heiminths, and almost all the Shanggalls. On the shores of Lake Zana live the Waits, who are considered heiminths, but they conform to most of the rites of the Abyssinian Church, except that they do not observe the fast of the Shanggalls, which amount to 129 days in the year, and some other observances of that community.

Political State and Towns.—For more than a century

Abyswinia has been in a state bordering on anarchy. An emperor, or as he is called a Negus, is the sovereign of the whole country, but his authority is only nominal, and his revenues consist of an annual pension of three hundred dollars, and the proceeds of a share of the trade of the market of Gondar. The governors of the provinces usurped his authority in their respective districts and transmitted it to their children. They are almost continually in a state of war with one another, and the stronger expels his predecessor and gets the chief of his rival, who are most in favour with him. The governor in possession of the town of Gondar creates the emperor. How rapid the political changes are, appears from the fact, that a few years ago the town of Falashabad, on which the capital had been transferred, was given to the village of Abdi, and some for only a few weeks or months. The country and population suffer greatly by these wars, to which is owing the destitute state of the greatest part of the country, but especially those parts of Amhara which lie north of Lake Zana, and are usually the theatre of protracted wars.

Under such circumstances it would be useless to attempt to give any account of the political divisions of the country. What was true three or four years ago, is probably not true now. It will also be conceived, that there is hardly a place which deserves to be called a town in our signification of the word. The manufacturing industry is too small to collect a number of individuals in one place, and each usurper chooses a new residence, according to his political views or his business interests. When the dominion of a chief, it acquires importance, but its ruin begins with his death. Thus the town of Antalo in Tigré, under the wire and energetic government of Ras Wellel Selassa, had so many inhabitants, that it was called Falashabad. But it had a population of 8000 inhabitants, but since his death (1810) it has fallen to decay; even Adowa, though a commercial place, is going to ruin. The town of Gondar alone still retains some importance, though it has greatly declined from its condition when the emperors had not yet lost their authority. The most important town in the Peninsula of the Abdi is Burie, the capital of Damot, but as the governor of the province has lately transferred his residence to Gonder, it probably so loses some of its greatness. Other towns of Abyssinia. The towns of Yawash and Yebuji, also in the Peninsula of the Abdi, appear to be considerable places. They are inhabited by merchants, who have acquired some wealth by their business in the neighbouring market-place of Bado.

The kingdom of Shoah forms an exception. Though this state is of modern date, its internal organization appears to have acquired a considerable degree of stability. It has also acquired a powerful authority, and it is able to maintain a numerous and powerful body of slaves, and of their chiefs, and enables it to keep them in check. The authority of the king of Shoah extends over the country north of the Hawsh from its source to its junction with the river Kassam (40° E. long.). From the last-mentioned place the boundary extends, being the western boundary of the empire, to 16 miles from the ascent of the table-land, until it reaches the river Berkona, an affluent of the Hawsh. The Berkona runs along the northern boundary on the east of the table-land. On the table-land itself the boundary is formed by the river Wast, an affluent of the Wasshilt, by the last-mentioned river and its recipient the Jamma. The western border runs along a line drawn from the point where the Jamma falls into the Abdi on the south of the Hawsh. Among the Galla tribes who inhabit the plains along the banks of the Hawsh, and who reside the western boundary, the authority of the king of Shoah has not yet been firmly established, but the other parts of the country are completely subject to his power.

The capital of Shoah is Ankobor. It is situated on the ascent of the table-land, not far from its upper edge, and 8198 feet above the sea-level. This town is built on two wooded hills, which are nearly north and south, the upper poles connected by branches of trees, like palisades, and on the summit is the king’s residence, built of stone, with a thatched roof and numerous outbuildings. The southern hill is cumbered with houses, chiefly of wood with thatched roofs, and they are generally surrounded by a gason, and wind round the cone in a spiral form. The population may amount to between 8000 and 10,000, exclusive of the king’s household, which consists of more than 1000 persons. The climate of this place is compared with a fine spring or autumn in England; the thermometer during August and September never rises above 63° or falls below 45°.
Manufactures.—When it is considered that the elevated table-land of Abyssinia is very difficult of access from the sea-side, and that therefore the intercourse between its inhabitants and foreigners has been very great, we must admit that they have made considerable progress in manufactures. They do not indeed excel in the fabrication of any article, as they have had no instruction from other nations, to which circumstance the manufactures of Europe in a great part owe their perfection. The best articles, or finished skins, and razors are only made at Gondar and at Kirata, a town situated on the eastern shore of Lake Zana, which contains 5000 inhabitants, and is used by the clergy, which circumstance profited it effectually against the evils of war. At Gondar there are guns made, but only by some Greeks, not by the natives. Large quantities of coarse cotton-cloth are made in several parts of the country by women, especially by the Falasabas, and a finer kind with a red or blue border for the more wealthy classes of society. The silk manufactures are limited to some embroidery, made by Mohammedans and worn by their women, and to blue strings, which are worn on the heads of all Christians, a mark of distinction from Mohammedans or heathens. Only a coarse stuff is made from the wool and hair of the black sheep and goats, which is also employed in making a kind of counterpanes. Coarse black pottery is made in every part of the country. Printing has been introduced into Abyssinia, and many scripts of manuscripts forms a distinct branch of manufacturing industry. Rüppel states that they have brought it to considerable perfection. Their handwriting is very fine. They use a kind of pen, and always copy on parchment. These manuscripts are embellished with pictures, which at present are indifferent; but Rüppel saw some which were made eighty years ago, which were much superior. He praises also the tasteful manner in which the binding of these manuscripts is executed.

Commerce.—As Abyssinia does not border on the sea, but is separated from it by the countries of the Danakil and Adal, it has no immediate intercourse with sea-faring nations, but its products are carried either to Massawa (15° 40' N. lat.) on the Red Sea or to Tajurnah (11° 50' N. lat.) built on an inlet of the Gulf of Aden. Massawa is about forty miles from the eastern boundary of Abyssinia, and through this place the maritime commerce between Tigre and Amhara and other nations is carried on. It is accordingly the harbour of these two great divisions of the country. Tajurnah is more than 200 miles from the nearest boundary-line of Shoa, and 372 miles from Kishwar, by the caravan road. The kingdom of Shoa has the shortest and the cheapest road. The unsettled state of the country obliges them to travel in caravans, and they always keep to the same routes. Gondar may be considered as the centre of this commerce, and with the exception of ivory and slaves it has long been engaged in this trade. Two caravans-roads lead from Gondar to Massawa. One traverses the table-land of Weggbera, and the pass of Lulambon crosses the Takkazie in Shiré, and continues through Axum and Adowa to the desert of the table-land. The other, having traversed Wasseha, turns eastward and passes over the Semien mountains by the Selki pass. It crosses the Takkazie at Ber Agow, and continues to Adowa, where it falls into the road before mentioned. Two caravan-roads from Gondar to Babo, which runs along the eastern shores of Lake Zana, crosses the Abá at the bridge which is below the cataract of Alá, traverses the plain of Miecha and the western portion of the Talla Walle range, passes through Dimebha in Danaza, and thence continues to Béa. The other more northerly, which goes through the commercial town of Dérita, which has not yet been visited by Europeans, and the market-place of Bada, whence it continues over the broken Bridge on the Abá to Mota and then to Pasaba. From these several others which by the interior commerce is carried on. There are a certain number of Austrian dollars circulating in Abyssinia. Rüppel thinks that they do not amount to a hundred thousand. The Abyssinians carry casks of pieces of coffee, weighing between 19 and 20 ounces. They are taken from the great salt plain, which properly lies in Adár, but partly belongs to Tigré (Adal, P. C. S.), and are carried by the merchants of Antidó to Sóctoa in Wæg, whence they find raw cotton and pepper, blue red and cotton-cloth, the threads of which are unrevelled and woven into the borders of the cloths of native manufacture, raw silk dyed blue, white camels, and some quantities of carded wool and common Turkish carpets. From Béa are imported bottles of a peculiar shape, of which large numbers are used in Abyssinia, and a large quantity of Persian tobacco.

The Abyssinia manufacturers have probably consumed there, but some of them find their way into the interior of Africa to supply countries and nations with whose names we are hardly acquainted. They are exchanged for the products of these countries. Béa is a market-place (a town) situated in Gojan, 15 or 18 miles from the most southern bend of the Abá river and a few miles from the towns of Yejñibi and Yauh, where many merchants reside. Dr. Beke has given some account of this trade. The market is held weekly during the harvest season, from April to October, during the other four months the river cannot be forded. The merchants bring from the southern countries slaves, ivory, coffee, civet, gold, cloth, iron, and cattle. While Dr. Beke does not mention the spice called "khito," which Rüppel enumerates among the articles of export from Massawa: Rüppel states that it is imported from Enarea. On comparing the imports from these southern countries with the export trade of Abyssinia, it is evident that most of the exported articles and also most of the imported are not of Abyssinian growth, and that this country produces very few articles for foreign commerce. Nearly all the merchants who come from these countries are engaged in slaves. Lord Valentia and Rüppel have given some account of the trade of Massawa. Rüppel stayed there nearly eight months, and got the following information about the exports:

All articles imported into Massawa go to Abyssinia, with the exception of a large quantity of rice from India, d’bours (Holcus sorghum) from Yemen, and dates from Béa, which are consumed in the town. The articles sent to Abyssinia are...
their way to the southern provinces of Abyssinia. These pieces of rock-salt are called zemole.

**History.**—There is a tradition in Abyssinia, generally credited, that one Lihime, a king of the country, in the 27th century before the Christian era, was converted to the Jewish faith, and that the founder of the first dynasty of their kings was Menilek, a son of Solomon and a queen of Saba. The Abyssinian tradition seems to be based on the fact that, at one time, the Emperor Constantine by some missionaries sent from Alexandria. At that time the capital of Axum was the seat of the empire, and most of the antiquities which still exist at that place must be ascribed to that period. The power of the empire seems to have been fast declining, and they got possession of the low country which divides the table-land from the Red Sea, and at present forms the country of Adal. In the sixth century they had so increased their power that they were able to send an army to Arabia and to conquer a part of Yemen. This was the period of the greatest political power of Abyssinia. Seventy years afterwards the Abyssinians were deprived of Yemen, probably by the Arabs, whom Mohammed had inspired with the zeal of propagating his doctrines, and who soon attacked Abyssinia itself, and though they did not succeed in conquering it, they took possession of Adal, and converted it into their own possession. They then retired for many years and doubtless crept into the internal affairs of the empire, for in the year 925 a Jewess, called Sague, overthrew the reigning dynasty and destroyed Axum. The descendants of the royal family fled to Sho. For more than three centuries that country remained a distracted state, until the Emperor Iqon Amlaq recovered the whole kingdom, about 1255, aided by the abilities of an ecclesiastic named Tecla Haimanot. In the following three centuries the power of her principal phases, of an improving state, and even to have acquired a part of its former power, as in the thirteenth century it is said to have again possessed the southern part of Adal, which however it lost soon afterwards. Towards the end of the fifteenth century Pedro Covimenes, an agent of the court of Lisbon, visited the country, and this circumstance saved the empire from destruction; for in the beginning of the sixteenth century, or perhaps even earlier, a salam of Hurur, or Adal, had, like Gengis Khan, succeeded in gathering under his banners the nomadic tribes of Dankali and the Gallas, and made frequent incursions into Abyssinia. The emperor sent an ambassador to Lisbon to get aid from the king of Portugal, at the same time promising unqualified submission to the pope. Four hundred soldiers, a considerable supply of arms, and some gold were sent to aid, but the emperor and the ecclesiastics opposed this innovation. For some time the matter was managed with prudence, but the ill-timed zeal of some Roman Catholic missionaries brought about a crisis: the people rose in rebellion, and the empire was transferred from Sho to Gonder. The mission of the Portuguese ecclesiastics however appears to have laid the foundation of that unsettled state of the country into which Abyssinia has sunk, and the intervals of its recovery are but the phases of a country which we have already noticed. It has been stated that after the defeat and the death of Granie, the southern provinces were not recovered; but it seems that in the eighteenth century, Ayine, and the region south of it, formed a possession of the Emperor of Ethiopia. All the most interesting and most ancient sites, such as the table-land, are in the elevated regions that border on the steep ascent from the table-land, and that these chiefs considered themselves dependent on the emperors. One of them, however, called Negosa, obtaining authority, and became the founder of the kingdom of Sho. It was not till the fourteenth century that it is stated the country had not yet had time to acquaint us with the history of its dynasty. Kraef however states that the present sovereign is the seventh king from Negasi. It would therefore appear that Nagasi lived at the end of the seventeenth or the beginning of the eighteenth century. His successors began to enlarge their territories; and the second of them took the name of Kraef, and expanded his dominions by a little more than a hundred years, and they have extended their authority over a country covering at least 12,000 square miles, and the order which they have introduced into the administration and the army, and the spirit of enterprise and energy which have been shown in their wars with the neighbouring Galla tribes.

**ACANTHODEPSMA.** A fossil genus of fishes from Glaros. (Agassiz.)

**ACANTHO'DES.** A genus of fossil Gnathostome fishes, established by M. Agassiz. The species occur in the carboniferous strata near Edinburgh. (Agassiz.)

**ACANUS.** A fossil genus of fishes, from Glaros. (Agassiz.)

**ACCELERATION AND RETARDATION OF HIGH-WATER.** The high-water at any place from which would be observed if the tides occurred after the lapse of a mean interval. The interval between the culmination of the moon, or the occurrence of high-water, and the time of high-water, is also called the retardation of the tide.

The tides are caused by the attractions exercised both by the sun and moon on the waters of the earth; but the effect produced by the moon exceeds that which is produced by the sun, and the difference is such that the phenomena of the tides depend principally on the former. The mean interval between two consecutive returns of the moon, above and below the pole, to the meridian of any place, is 24h. 50m. 28s. 22; and since, neglecting all causes of irregularity, two lunar high-tides occur in that time, the mean interval between two consecutive lunar tides should be 12h. 25m. 14' 16s.; while the mean interval between two consecutive solar high tides should be 12h. Hence, if at the time of a high-water, or at the highest point of the sun and moon, the high tide which is produced by the actions of the luminaries separately were coincident, the next lunar tide would be retarded with respect to the next solar tide, by 25m. 14' 16s., that is, by the excess of half a lunar high-water above half a solar high-water. Now, if the sun and moon are in conjunction, or in opposition, at the summer or winter solstice, the retardation is equal to 40m. 51' 59s., and at the time of the equinoxes 37m. 35' 15s. Again, when the sun and moon are in quadrature, the retardation is 24h. 27' 49s., and at the time of the equinoxes 1h. 25m. 16' 34s.

If the earth were a solid of revolution, and were covered by the sea, the high-tides produced by the sun and moon separately would, at any place, occur at the instants when those celestial bodies were at the meridian of the place; but such is not the fact in the actual condition of the earth; and local circumstances produce, at different ports, great differences in the intervals between the culmination of the sun or moon and the time of high-water. Even these, however, are not in conjunction or opposition. The interval between the instant that the sun passes the meridian of a place and the occurrence of the solar high-tide, is found to be greater than the interval between the transit of the moon and the occurrence of the lunar high-tide. The latter is called, of the lunar tide, with much probability ascribed by Dr. Young to a difference in the resistances experienced by the waters on account of the different velocities which are

**P. C. S., No. 4.**

**ACC.**

**VOL. I—E**
communicated to them by the separate actions of the sun and moon.

It should be observed however that at Greenwich the time of high water above that of the morning for the day varies slightly as the moon passes the meridian of that port; and both at Glasgow and Greenock the high-tide generally precedes the transit (Mr. Mackie's Report, at the seventh meeting of the British Association); but such phenomena are of rare occurrence, and in some particular cases the high-tide occurs some time after the moon has culminated.

From a series of observations continued during sixteen years, at Brest, La Place, taking the excesses of the height of the evening tides above that of the morning for the day, is directed to the high-syzygy, for the day preceding it, and for four days following it, has ascertained that at the syzygies which occur about the vernal and autumnal equinox the highest tides at that port take place 1490 minutes after the conjunction or opposition of the syzygies; and at the syzygies which occur about the summer and winter solstices they take place 150684 days after conjunction or opposition. Again, taking the excesses of the height of the morning tides above that of the evening for six days, as above, he ascertained that at the quadratures which occur about the equinoxes the highest tides take place 150964 days after the instant of quadrature, and at the solstitial quadratures 151299 days after such instant.

H. C. Frayer ('Tides and Waves, etc.' Metro.' observeth that these retardations cannot be accounted for by delays in the transmission of the tide-waves, since no cause for such delay can be imagined to exist in the Southern Ocean, where the waves are formed; and it is known that the time of high-water is retarded by from fifteen hours at 57º South to 1h. 1m. at the Cape of Good Hope: he conceives therefore that the retardation must be ascribed to friction. By taking the means of the daily retardations of the morning and evening tides at Brest, La Place found that at the equinoctial syzygies the mean retardation was equal to 37m. 38s.; at the solstitial syzygies, 40m. 52s.; at the equinoctial quadratures, 83m. 16s.; and at the solstitial quadratures, 76m. 27s.

From a series of observed heights of the tides, Sir John Lohum was first to determine that the highest tides occur at London on the 3rd of March after the conjunction or opposition of the sun and moon; and at Liverpool, 1h. 66h. (Phil. Trans. 1831, 1835). Also, from the observed heights, Dr. Whewell has found that the highest tides occur at Bristol 1h. 66h. days after the syzygy; and at Dundon 1h. 69h. days. (Phil. Trans. 1838, 1839.) On the assumption that the mean retardation of the tide at London at the times of syzygy is 2h. 45h. days, Mr. Airy has computed the moon's true hour angle west of the meridian at the time of high-water, for every half hour's difference in the time of her transit; and from the table it appears, that when the moon passes the meridian of London at noon, the angle is, at the time of conjunction, that angle, in time, is the highest; and if it passes at the angle of 10m. 45s.; at 6 h. m., or at quadrature, oh. 41m. 17s.; and at 9 h. m., 1h. 55m. 29s. The hour angle is the greatest at 10h. 35h. when it is equal to 2h. 9m. 56s.; and at 1h. 59h. m., or nearly at the time of opposition, it is 3h. 3m. 6s.; all these times are found to agree very nearly with the results of observation. From such results it is ascertained that, on the days following the times of syzygy and quadrature, the intervals between the time of the moon's transit and the instant of high-water are nearly equal; but from conjunction to the first quarter, and from opposition to the third quarter, the intervals are less than on the days of syzygy and quadrature, or the time of high-water is accelerated; while from the time of the first quarter to that of full moon, and from the third quarter to the time of low-water, the interval is less, and of high-water is retarded. The time first mentioned (1h. 57m. 17s.), is that which is called the Establishment, at London; but Dr. Whewell recommends that the mean of the times (1h. 58m. 32s.), which is only to be deduced from the observation of the moon's transit, or, when that is not possible, from the establishment, should be used in preference, because it differs less, on any day, from the vulgar establishment.

From Dr. Whewell's paper in the 'Philosophical Transactions' for 1836, we find that at Liverpool, when the moon passes the meridian the time of high-water is 11h. 18m. 16s.; when the hour of transit is 6h. 3m. 10h. 40m. 52s.; and when it is 11h. 35m. 30s. The mean, or correct establishment, is 1h. 58m. 35s.

The acceleration and retardation of the times of high-water must evidently depend on the distance of the moon from the earth, and they are presumed to be proportional to the difference between the actual and the mean horizontal parallax of the luminaries: this is called the parallax inequality of the tides; and La Place has determined, for the lunar tides, that the error in this respect is about 0.0112 of the mean value of the parallax, and in perigee, is nearly 0.0279 to 0.099. He estimates the variation at 9m. 26h. 4s. for a change equal to one minute in the moon's apparent semidiameter at the times of conjunction and opposition, and at one-third of this quantity at the time of quadrature. Correlation is in this case, but less amount, take place with respect to the solar tides.

ACIDENTAL COLOUR is a name given to that which an object appears to have when seen by an eye which, at the time, is in a state of excitement caused by incapable sensations, or by the loss of one or more of the pure colours. In this case, there is a passage in one of the chapters of the 'Trattato delle Pitture' by Da Vinci, in which, as a reason why, on a white wall, the shadows produced by the setting sun appear to be blue, it is stated that the reflection of the azure tint of the sky is on the walls, and that the light of the sun, on which it falls does not receive the red light of the luminary. The variations produced by causing the colours observed in the shadows of small objects to fall upon one another were noticed by Buffon, and Dr. Jurin (Tractatus de indirecte vision, in Smith's Optics) described the apparent images produced by looking intently, for a time, at a black object on a white ground and at a white object on a black ground.

But Buffon was the first who made a series of observations on the accidental colours of various objects, and the object which he acquired a perception when the eye had been for some time directed to an object of some particular colour; and it is he who gave the name of accidental colours to those which we so perceived. In a 'Mémoire' presented to the Académie des Sciences in 1743 he gives an account of his observations, the substance of which is, that when the eye had been, for a certain time, directed steadily to a square spot of one of the following colours, red, yellow, green, blue, black, the object being placed on a white ground, there was seen about the spot a fringe or border of one of the colours in the following series: green, blue, pale purple, pale red, white, which, in order of the circle of the colours, were visible, one after another, in the former series. Immediately afterwards, on directing the eye to a different part of the white ground, there appeared upon it a square spot of the same accidental colour, the white spot being considerably brighter than the ground.

The subject of accidental colours was pursued by the Jesuit Scherffer ('Institutionum Opticarum partes quatuor,' 1775), and he recommended that, except when the object viewed was black, that object should be placed on a black ground; in order that, with less fatigue to the eye, the accidental colours might be more vivid when the eye was directed to the white ground on which they were to be perceived. Scherffer made observations with coloured spots on grounds of different colours, from which he ascertained, at the same time, the accidental colour of the eye. He observed, in direct contemplation of a red square placed on yellow paper, and then turning the eye to white paper, he found that the latter was of a blue colour, and that on it appeared a square coloured green. But Buffon subsequently observed that, if the eye during a longer time than was necessary to produce the border above mentioned, observed that the colour of the spot itself became less vivid, that the spot subsequently took the form of a cross, and, finally, that of a narrow rectangle, which was directed parallel to the long axis of the eye, and in perigee, is nearly 0.0279 to 0.099. He estimates the variation at 9m. 26h. 4s. for a change equal to one minute in the moon's apparent semidiameter at the times of conjunction and opposition, and at one-third of this quantity at the time of quadrature. Correlation is in this case, but less amount, take place with respect to the solar tides.
or springs, fixed in tubes, and acted on by the breath of the performer, which is in common use with the people of that extraordinary country. An engraving of it is given in the 

**ACCOUNT STATED.** This is the title of the common count in an action at law for the amount due upon a balanced account between the parties, the form of which is that the plaintiff shall, the plaintiff or his agent, a certain sum of money found to be due from the defendant to the plaintiff upon an account then stated between them, and in consideration thereof promised payment. This form should always be taken by the defendant upon a simple contract for the recovery of a pecuniary demand.

It is not essential in support of this count that there should be reciprocal demands between the parties, or that the account should relate to more than a single debt or transaction. The original demand need not have been one recoverable at law. It may have been equitable, as in the case of a claim against an executor to recover a legacy to which he has assigned, or in that of a member of a copartnership, who, though he cannot in general sue his copartner at law for his share of the profits, may do so after an account has been stated between them and a balance struck in his favour. It is necessary however that there should have existed some claim against the defendant, or some previous transactions in respect whereof, for which the account is stated, the defendant thereby made. This is in form upon a mere agreement to pay a sum of money.

It is usual in support of this count to give evidence of an original demand or a prior transaction, and of a balance struck thereupon, which may be sufficient to prove an admission by the defendant to his agent, that a certain sum was then due, without showing the origin or nature of the claim, or proving the specific items constituting the account. The account must have been stated before the action is brought. The defendant, in order to charge a defendant upon an account stated, must be positive, unconditional, and contemporaneous, and must not merely the admission of a debt, but either expressly or by reference thereto, have provided a sum by which he is liable in cases in a representative character, as in that of executor or assignee, he must show that the admission was made to him in that character. The statement of an account is it seems only presumptive evidence against the party who admits the balance to be against him, and does not prevent him from showing by clear evidence the existence of error in the account; unless in the case of an account actually settled by payment, which cannot be opened except upon proof of fraud. (Chitty on Contracts, 5th ed., c. 18, p. 466.)

In order to support this plea the statement of the account must be shown to have been final, and to have been in writing; but it is not essential that it should have been signed by the parties, and it will be sufficient if the account has been compiled for any purpose, and demonstrated to afford legal presumption of a settlement. A general release not under seal may be pleaded as a stated account. A plea of this kind must aver that the account is just and fair, whether error or fraud is charged by the one or other party.

In answer to a plea of a stated account the plaintiff may show either the existence of fraud, which will be a sufficient ground for opening the whole account, or that the account contains specific errors, which will enable him to surmount the objections on the ground of error. The plaintiff is entitled to show that a demand has been made, or other accommodation for the account, and that the demand was refused. The plaintiff may be called in by a trader to investigate his accounts and to ascertain the state of his affairs. The collection of debts or rents, and the winding-up of affairs of persons deceased, or who have given up business, are matters often put into their hands, and auctioneers and auctioneers frequently act as accountants. An accountant has no legal status, like a notary or an attorney or appraiser, who perform certain duties which none but they are allowed by charter to perform; but in the Chapter Act (5 & 6 Vict. c. 129) official assignees must be selected from persons in trade, or who have or have been 'merchants, brokers, or accountants.' The
The simplest case in which there is such an accumulation of power is that of a heavy body, like the rammer of a pile-driving machine, which descends by the action of gravity during a certain time and impinges upon some object. At the moment of contact the body might be supposed to move, the velocities of all the particles, which had gone on continually increasing during the descent, are destroyed, and thus a shock is produced immensely greater than that which would result equally from the instantaneous exertion of a master ram of the antients, when, being suspended from some fixed point, it was allowed to swing by the action of gravity till one of its extremities struck the face of a wall, produced its effect in like manner by the power accumulated in it during its motion. In all such cases the effect, if measured by the magnitude of an impression or indentation produced in the object struck, is, by mechanics, directly proportional to the mass in motion and to the square of the velocity at the instant of impact. The acceleration produced by the suddenly exerted action of gravity, when a body has not far to fall, is commonly increased by that of a quantity of motion obtained by an exertion of muscular power. Thus a smith, when he would strike on an anvil with the greatest force, adds to the power of gravity on the hammer the accumulation of velocity arising from a whirling motion, in a vertical plane, which he gives above his head to the hammer before he allows it to descend.

In the old coining-machines, which, like those that present the most perfect and closest analogy to the mechanism of a screw, a great accumulation of force was obtained by causing a number of men to turn the horizontal bars attached to the vertical shaft which carried the screw: by the pressure of the men against the bars, while several revolving cylinders were in motion, there was an accumulation of motion during that time took place; and the accumulation was instantaneously spent upon the metal, in aid of the power arising from the power of the screw alone. The like accumulation of force is obtained, but far more efficiently, in this coining-machines, and a present day by means of its fly-wheel: the reciprocating motion of a piston connected with a steam-engine communicates, by means of a crank, a continuous circular movement to the fly, and at the same time a rapid digging movement to the fly-wheel, a cylindrical shaft (the stamper) on which the screw is formed. With half a revolution of the fly-wheel the stamper is lifted up, and with the other half it is forced down upon the metal. When a fly-wheel is set on by any prime mover, as wind, water, or steam, its motion continually accelerates, and a corresponding acceleration is induced in the wheel-work, in rollers, or in the stampers with which it is connected: the resistance to be overcome at what is called the working point destroys however this acceleration, and when the movement is uniform, if it were not for the temporary accelerations or retardations which are caused by variations in the intensity of the moving power, or in the amount of the resistance; and these are almost wholly counteracted by the accumulated power, which is produced by the former and is exerted in a radius, and W the weight of the wheel; the effect at a working point, when the latter is connected with the axis of revolution at a distance from it represented by r', being, to the effect at the circumference of the wheel, as r to r', we should have \(\frac{r'}{r}\) to represent the effect at such working point.

Consequently, the place of the working point being given, it should follow that it is more advantageous to increase the diameter of the wheel, or its velocity, than its weight: but in practice, there are certain limits both to the magnitude and the velocity of the wheel, which must not be exceeded, lest the centrifugal force arising from the revolution should destroy the cohesion of its parts.

ACERATHE'RIUM. Some fossil Rhinoceratae have been thus named by Kaup.

ACELIUM, A, a genus of fossil Madyrphyllia.

ACHILLEUM, a genus of fossil Spondiophiæ, of which two species occur in the cretaceous strata of England. (Goldfuss.)

ACIDASPIS, a genus of fossil Crustacea, of the group of the Trilobites, found in the Wenlock limestone. (Murchison.)

ACONITUM (Monshahod, or Wolfehne), Medical Properties of—The botanical characters of this genus of Ranunculaeae plants have been already given. [F. C. vol. i. p. 88.]
The species merits the preference as a medicinal agent, is a greatly controverted point. The London and Dublin Pharmacopoeias, following the notions of Decandolle as to the identification of his Achomine, the Aconitum Napellus officinalis, figured by Steck in his 'Libellus de Stramonio, Hysocyamino, Aconitó,' Vindobon. 1762, have given that as the official one, while the Edinburgh College has retained the common A. Napellus. The preponderance of evidence in most cases, however, precludes the opinion of the former, and the almost impossibility of procuring the plant indicated by the two former, since it is only a rare inmate of botanical gardens, it is substituting a considerably less potent for a more potent plant. The Aconitum varieties are of the glands in the root of the plant possessed of great acrimony, while A. paniculatum has scarcely a perceptibly acid taste. The official parts are the root and leaves, but the seeds might be added with propriety. Every part of the plant has a narcotic-acrid property. The live plant, when crushed, produces a fluid resembling that of the pot-herb, while the dried plant is only a tar of an astringent nature. The great difference is that while the root of A. Napellus has bitherto been published, though Pallas analyzed the root of A. Lycocyatum, and Bucholz the leaves of A. Medium, Schrad. It is probable that all the species contain similar constituents, differing only in degree, the most powerful being the A. Ferox (Wallich, Fl. Asiatic, Rariores, i. t. 41) or Blask of Northern India. The most important are the alkaloid aconitine, aconitic acid, a fatty oil, and perhaps a volatile acid principle. The latter probably results from the decomposition of aconitic acid by the action of heat. Almost all ranunculous plants have an acrid principle, which is very easily driven off by heat. Much care is therefore requisite in drying the root or leaves of aconitine, as the volatile tincture is volatile. The essential oil is required in forming the extract or in aspirating the juice. A knowledge of this fact leads to the most convenient and effectual antidote in cases of poisoning by these plants, viz., causing the patient to drink very warm water till vomiting is excited, or washing the eye with warm water, by which it could be used as a pot-herb, by merely boiling it, and adding a little fat or butter. (Linnaeus, Flora Leopponica, p. 187, ed. Lond. 1792.)

The evil oil is destructive of the sensibility of any part to which it is applied, but whether from inherent powers or from having aconitine dissolved in it is yet unknown. The alkaloid is regarded as the efficient principle when aconite is used medicinally. The forms of administration are various. Powder, Roots, Leaves, Oil, and sometimes in solution. This further varies with the period when the leaves are collected. The best time to gather them is immediately before the flowers wither, when the seeds advance to maturity the sooner. It is also probable that the more juicy and fresh the plant is when the seeds are intended to be collected, this should be done just before they are perfectly ripe. The root should be taken up before the flowers expand; it must be carefully, yet speedily, dried. It is sometimes dried in the sun, but this is not the best mode and its activity is impaired, while a high temperature quite dissipates its valuable properties. The watery extract is a worthless preparation; and the infusium of the London Pharmacopoeia, improperly termed an extract, is also objectionable, being a mixture of the leaves, or an alcoholic tincture of the root made by distillation. The insufficiency of the watery extract and infusium has led to statements in some popular treatises that it may be given in the dose of twenty grains, a quantity which would probably foul when the extract is prepared with alcohol. Of this latter it is rare that two grains can be given with safety: a quarter of a grain is serviceable to begin with. Possessing a toxic-acrid property, the action of aconitine on the human frame is different according to the quantity used. In small medicinal doses its most obvious action is purely local; in larger, its action is both local and remote. Thus a small portion of it is absorbed by the local effect of its power by numbness of the lips and tongue; increased secretion of saliva also occurs. Minute doses taken into the stomach cause augmented secretion both of the mucus membrane and saliva, and if taken in sufficient quantity, the appetite is often markedly increased; while tingling of the extremities, with heat, is often felt, and either perspiration or increased action of the kidneys. The effect on the pupil is variously stated. Geiger affirms that aconitine produces dilatation of the pupil. Dr. Feit, in his German article on 'Aconitum officinale' in the Materia Medica, that the external application of it produces contraction; while in his experiments with the extract of the Aconitum ferox (recorded in 'Edinb. Journ. of Natural and Geographic Science,' July 1830, p. 255) he distinctly affirms that while the animal continued alive the pupils were 'much dilated,' contraction taking place only after the animal was apparently dead. Large doses cause redness and inflammation of the parts brought in contact with it; but the intellectual and emotional effects are voluntary, or it becomes an overstimulation. Sir B. Brodie thinks that it occasions death by destroying the functions of the brain. ('Phil. Trans.' 1818, p. 186.) For this effect do not consider absorption necessary; there is separated from it an alkaloid which, by increasing the intensity of its remote action on the nervous system is in proportion to the absorbing powers of the part to which it is applied (loc. cit. p. 242). The susceptibility of the heart to aconitine is greatly increased by it. When first introduced into medical practice it was recommended in many diseases; but it is now almost entirely restricted to painful affections of the nerves, and to rheumatic complaints, particularly when they are complicated with fever. For these effects it is not injurious. The stomach is affected more externally than internally, but this last mode is to be commended at the same time. An ointment is formed with one or two grains of the aconitine to one drachm of linseed. A small portion of this is to be applied frequently to the part affected. An eruption sometimes appears, especially if the ointment be strong. The internal use of aconitine is scarcely to be advised, one-fiftieth of a grain having endangered the life of an adult. The very high price of this article is an obstacle to its extensive employment; but ingenious chemists are endeavoring to simplify the process of extracting it. To obtain it perfectly pure it is almost essential to use sulphure ether in the preparation of it, which necessarily increases the expense. The incidence of chronic rheumatism, and even in some cases of acute rheumatism, should poisoning occur, attempts must immediately be made to empty the stomach by emetics or the stomach-pump. No brandy or other form of alcohol should be given, nor vinegar, till all the benefit removed from the, in Materia Medica, which coffee with vinegar is very useful: venesection sometimes may be required.
properties of some of the Aracem. The Acoruc calamus is a British plant, and has slightly aromatic properties. (Lindley, _Nouveau._) [Acorus, P. C.]

ACQU, the name of one of an administrative division of the Sardinian States, situated on the northern side of the Ligurian Apennines, the ramifications of which run northwards until they slope down into the great valley of the Po. The Bor- nida, the Po, the Tanaro, and other rivers, or torrentes, which rise in the main ridge of the Apennines, flow between these offsets until they all join the Tanaro, which is the greatest affluent of the Po on this side. The province of Acqui is called the Piglio or Upper Monferrato, being part of the Montferrato of that name which was annexed to the dominions of the House of Savoy. The country produces some corn and much fruit. The lower hills are planted with vineyards, from which good wine is made, known and sought after by the name of Monferrato wine. The mountains are partly covered with chestnut-trees, which supply an article of common food for the peasantry. The rearing of silkworms is an important branch of industry. A considerable quantity of cattle, especially borred cattle, is bred in the province.

The province of Acqui is bounded on the north by Alessandria, east by Novi, south by Savona, and west by Alba. Its length is about 40 miles north to south, and its greatest breadth is about 30 miles. The population is distributed among 73 communes. The head town of the province is called Acqui, and is a bishop's see. It is built partly at the foot and partly on the slope of a hill on the left of which stands the castle of Borinda, with a handsome façade, several other churches and convents, a royal college, a clerical seminary, and a town-hall, some other remarkable buildings, and about 7,800 inhabitants. The old walls of the town have been pulled down since the last peace of 1815. The old castle stands on a hill outside the town, and is used as a prison. The town has some manufactories of linen and some tanyards. Acqui is much frequented by invalids from Lombardy and from Geneva for its hot sulphur springs; the establishment for bathing is about a quarter of a mile out of the town, on the opposite or right bank of the Borinda. The buildings have been restored and enlarged by the late king, Charles Felix. The 'fangio,' or mud formed by the sediment of the water, is applied in many cases of local complaints or old wounds, and is considered very efficacious. The town derives its name from its springs, which were known to the Romans by the name of Aquae Statii, Statiiell being the name of a tribe of Ligurians who inhabited this region, and who being joined by other tribes were defeated in a great battle near Carthage by the consul M. Popilus Licinius, 173 a.c. The consul raised Carthage to the ground, devastated the whole country, and sold many of the inhabitants. His severity was considered excessive even at the time. In the 18th century, Borinda was born a second time against the Romans until the other Ligurian tribes made a gathering in their territory, where they were attacked by the consul. The senate ordered the captives to be restored to liberty and the land was ceded to the Romans in so-called, 'the chase;' gracing its resolution by the well-sounding moral, 'that the splendour of victory consists in subduing an enemy in arms, and not in oppressing those who have submitted.'

The decree however was eluded for a time, and Popilus in the face of it again attacked the Statiiell in the following year, and killed ten thousand of them. At last the senate and the people joined in reproving the conduct of Popilus, who was summoned to Rome to answer for his conduct, and his brother C. Licinius, consul for the year, was ordered to execute the former decree and liberate the surviving Statiiell, several thousand of whom were released from slavery, and settled on some grounds which were assigned to them north of the Po. M. Popilus Licinius applied before the priest, C. Licinius, who being taunted with it by the friends of the accused, put off the matter to the Ides of March, when the new magistrates came into office, and Licinius retired into private life, by which means Popilus came off unpunished. "The cause," says Livy, "by an old saying, tricked the rogation concerning the Ligurians was eluded." Afterwards the mineral springs above mentioned having attracted the attention of the Romans, the place became known by the name of Aquae Statiiell, and there are inscriptions remaining which relate to the caro taken of the thermal, or warm baths, by the local officers.

In the early part of the middle ages Acqui was a countship, one of the early counts of which was a certain Alermannus, whose history has been interspersed with wonderful tales by the chroniclers; be fought valiantly against the Moors or the Saracens, and invaded Liguria. He married a daughter of Berengarini II, son of Otto I, and made a marquis, and died a.d. 993. He was the progenitor of the Marquises of Monferrato and of the Marquises of Saluzzo, who figured for centuries afterwards in the vicissitudes of the Sardinian States.

The other towns of the province of Acqui are—1. Nizza della Paglia, called also Nizza di Monferrato, situated in a pleasant district on the banks of the Belbo, with about 3,500 inhabitants, situated between the provinces of Alessandria, and Genoa, from which it is divided by the torrent Monferrato and a small town, known for its good wine. A number of small villages, or hamlets, from 200 to 2,000 inhabitants, are scattered throughout the province.

(Casali, _Dizionario Geografico, Storico, Commercial, degli Stati di S. M. il Re di Sardegna; Demania, Quadro dell'Alto Italia; Calendario Sardo._)

ACRE, SAINT JEAN D', the celebrated fortress on the coast of Syria, was taken by the united English and Aus- trian squadrons in 1840, after a bombardment which was short, but so effective as to form one of the most memorable events in the career of Napoleon. It was the first attack on Syria, Prussia, Russia, and Turkey, having concluded a treaty at London on the 15th of July, 1840, for the purpose of driv- ing the Egyptian troops out of Syria, and restoring this coun- try to the Moslem inhabitants, the sultan wishing to have an Austrian fleet attacked and took the Syrian seaports. On the 2nd of November, 1840, this fleet arrived off Acre: it con- sisted of seven English line-of-battle ships, four war-steamers for throwing shells, and some smaller vessels, commanded by Admiral Sir Robert Steph, who was commander-in-chief of the united fleet, and under whom Sir Charles Napier acted as commodore of the English squadron; and two Austrian frigates, the Medes, on board of which the Austrian admiral, the Marquis de Bans, had hoisted his flag, and the Guntz, commanded by Captain the Archduke Frederick of Austria. The attack began on the following day, the 3rd of November. The ships had some difficulty in taking their positions, as the officers had no good chart of the coast nor plan of the fortress, which, through the care of the pasha of Egypt, Mehemet Ali, had been made almost impregnable, except to troops and officers who combined the most consum- mate skill with the utmost bravery. After a heavy firing of two hours, which was well answered by the Egyptians, the grand magazine blow up with a tremendous explosion, pro- bably ignited by a shell from one of the steamers. Two entire regiments of infantry, which were standing in battle array near it, were annihilated, as well as all vessels crowded with marines and other troops, and beams of the building was thrown into the sea. The whole command nevertheless continued to defend the town, but the fire of the ships was so effective that it was discontinued at sunset, and the admiral prepared for a storm on the following day. This lasted three days, and the Austrians and Turks had not disturbed the fort during the night of the 3rd of November with the feeble remnant of his garrison, the force of which was from 4,500 to 6,000 men before the action. On the 4th the Anglo-Austrian force took possession of Acre: they met some men by a second explosion, the blowing up of a magazine of loaded shells which had been covered by the rubbish of the grand magazine, under which fire was smouldering. The allies lost eighteen killed and forty-one wounded. Lieutenant-General Sir B. H. Disraeli, commanded the British forces. After the fall of this bulwark of Syria, Ibrahim Pasha evacu- ated that country and retired to Egypt. Acre has since been restored to the Turks, and some care has been taken by them in rebuilding the fortifications, but the whole is still but little more than an indefensible heap of ruins. (Sir Charles Napier, _The War in Syria._)

ACRO'CLULIA, a fossil genus of Gasteropoda, allied to the Neritacea. It occurs in Paleozoic strata. (Philipson, _Dict. Nat._) [Acroclulius,] is a species discovered and described by M. Agassiz. The species occur almost exclusively in the liss and oolite. One British species (A. minima) is referred to the keuper series by M. Agassiz. It occurs at Aust Cliff in the Wiltshire Down. The others abound at Lyme Regis, Bath, and Stonefield.

ACRO'GASTER, a fossil genus of fishes. (Agassiz.)

ACRO'GNATHUS, a genus of fossil Cylindoids fishes, found in the chalk of Sussex. (Agassiz.)
ACROPLEIS, a genus of fossil Gondwanian fishes, found in the magnesian limestone of Durham. (Agassiz.)

ACROSALENIA, a genus of fossil Echinoderms. (Agassiz.)

ACROTEMNUS, a genus of fossil Gondwanian fishes. A fiba is found in the chalk of Sussex. (Agassiz.)

ACTA SANCTORUM. [Bollandists, P. C.]

ACTING: [Phil. Trans. 1842, p. 175.]

 ACTIONS must be made at stations differently elevated above the general surface of the earth or sea. It may also be employed to determine the diminution of heat which takes place during eclipse of the sun.

ACTION (at Law). [See P. C. vol. I. p. 106, for Actor, definition of; general object of; general principle respecting: three kinds of; general outline of proceedings in.]

ACRITARCH. [Baj. and Lyc. Ph. 1865.]

On this head there were many remarkable discoveries proposed by the late Mr. Miller of Bristol, upon the supposition that the species which he ranked in it had true alveolar cavity or phragmacone. The correctness of this view is doubtful. The space shown to be the crestaceous strata. [Delem. E. P. C.]

ACTINOCERAS, a genus of Cephalopoda, recently discovered by the vessel Siman, off the coast of Brazil. It is noticed under the word THERAPODIA.

ACTINOMETER (from deriv, a sunbeam; and pipos, a measure) is an instrument employed for the purpose of ascertaining the intensity of heat in the direct rays of the sun.

ACTINOMETER (from deriv, a sunbeam; and pipos, a measure) is an instrument employed for the purpose of ascertaining the intensity of heat in the direct rays of the sun. It is a highly delicate thermometer, having a large cylindrical bulb filled with ammoniac-sulphate of copper (a deep blue fluid), and a capillary tube, to which a graduated scale is applied. It was invented by Sir John Herschel, who gave a description of it, which was read before the Royal Society, on the 9th of June, 1835 (vol. iii.). The construction of the instrument and the manner of using it are noticed under the word THERMOGRAPH, P. C., p. 350.

The indications of heat afforded by the actinometer depend evidently upon the magnitude of the beam of light which falls upon the bulb and upon the bore of the tube, within which the heat rises from the effect of the beam. The area of a longitudinal section through the axis of the cylindrical bulb, which is also the area of a transverse section of the beam of light incident on the bulb, is taken for the former; such sections, in different instruments, being proportional to the semi-cylindrical surfaces which receive the beams; and the volume in the interior of the capillary tube, of one of the spaces corresponding to the length of the tube, measures the expansion of the fluid produced by a portion of the heat. This volume is found by measuring the volume of mercury which would fill a given length of the tube, and it should be determined by the maker of the instrument before its parts are put together.

The length of a degree on the theromometric scale is at present arbitrary, and the relative values of the degrees on the scales of different instruments are determined by comparing together the indications made in like circumstances. For this purpose, different persons may make observations simultaneously with the instruments, or the same person may make several observations with two instruments, exposing them alternately to the sun, in order to see if any difference in the results obtained by the different instruments is to be observed. The indications given by two instruments may therefore be adjusted by means of a comparison of their indications, or by means of the corrections to be applied to their indications. The indications given by two instruments may therefore be adjusted by means of a comparison of their indications, or by means of the corrections to be applied to their indications.

APPARENTLY "ADCA", ACTINOCERAS, a genus of Cephalopoda, recently discovered by the vessel Siman, off the coast of Brazil. It is noticed under the word THERMOSTIC.
operation of law. Thus the rights of action of a bankrupt or insolvent pass (with certain exceptions) to their assignees; and upon the death of a number of the parties between whom a cause of action has arisen, the right of maintaining such action survives in general to or against his executors or administrators. But in respect to suits which are founded on the violation of person or property, in case of an action that is that they die with the person, and by the common law this extended to every case of tort; but it is now no longer the rule as regards torts committed in respect of property. (4 Edward III. c. 7, and 3 & 4 William IV. c. 49, s. 2.)

7. The report of acts of an action at law are:—1, the process, or those proceedings which have for their object the compelling the defendant to appear, that is, to admit that he has a general intimation of the suit, and is ready to receive more particular informations of ground and cause; 2, the pleadings, 3, the trial and evidence; 4, the judgment; 5, the writ of error (where the judgment is supposed to be erroneous); 6, the execution. 8. By the stat. 2 Will. IV. c. 39, and the rules of court founded upon it, and by statutes 3 & 4 Will. IV. c. 67, and 1 & 2 Vict. c. 110, it is now provided that all personal actions shall be commenced by writ of summons, which is a writ issued out of the court in which the action is brought, directed to the intended defendant himself, and which, without setting forth the particular cause of action, but merely describing the action as one of debt, trespass, or the like, commands him to cause an appearance to be entered therein within eight days after the writ shall have been served upon him; 9. As to the passing of the above-mentioned statute a plaintiff might commence an action of debt by arresting the defendant where the alleged subject of dispute was a debt to the amount of 20l. at the least. Arrest on mesne process, that is, the first stage of the action, is now abolished.

(Army. P. C. S.)

(For further particulars see references in P. C. Vol. i. Action; and Blackstone, Comm.; Stephen, Comm.; Stephen, On Pleading: Chitty, On Pleading.)

CASE UPON THE CASE. [CASE, ACTION UPON P. C.]

ACTION AND REACTION. [MOTION, LAWS OF P. C.]

ACTION, LEAST, PRINCIPLE OF, is a name given by Lagrange to a law of motion which he has thus enunciated:—In a system of moving bodies, the sum of the products of the masses of the bodies by the integral of the products of the velocities and the elements of the spaces passed over, is always a maximum or a minimum.

The principle, in a limited sense, originated with Mauertus, who, in his Mémoires de l'Académie des Sciences de Paris, for 1749, designating it the Law of Rest, states that when bodies in motion act upon one another, the sum of the products of the forces by the velocities described, is a minimum; and from this principle he deduced the laws of the reflection and refraction of light, and of the collision of bodies. Euler also, in his Traités des Irémpériables Aimables, (1741), showed how to describe curves and lines by means of central forces, the integral of the product arising from the multiplication of the element of the curve by the velocity is always a maximum or a minimum. But the generality of the principle was established by Lagrange, who has extended it to a system of a motion of bodies acting upon one another in any manner whatever; and his first applications of it to the solution of dynamical propositions are contained in the second volume of his Mémoires de l'Académie, S. de France.

The analytical expression of the principle is, that 
\[ f(x) = \sum \frac{d^2}{dx^2} \]

or \[ f'(x) = \sum \frac{d^2}{dx^2} \]

is a maximum or a minimum, or that the infinitely small variation of that quantity is zero. (Here is the case of the velocity of a moving body.)

\[ d^2 = \sum \frac{d^2}{dx^2} \]

is the expression for the active or living force of a finite number of bodies or molecules [Vis Viva, P. C.]; and it follows that the principle of least action is the equivalent of the expression that the integral of the product of the living force of a system of active and passive forces of time, is always a minimum.

The truth of the principle of least action may be readily proved by several general dynamical expressions of velocity, P. C., p. 380, col. 1, the sum of the terms containing \( X, X, X, X \), being made equivalent to \( \sum x^2 \), or to \( \sum x^2 \), conformably to what is shown in the article just quoted; and

the whole being transformed agreeably to the process used in the Mécanique Analytique (sect. iii. No. 30), the use of the principle is only to serve as a rule for forming the differential equations of motion, and these may be obtained at once from the General Equation to which is reduced the whole system.
customary of the debtor. Within a quarter of a year the chattels and lands were to be delivered to the creditor for sale in payment of his debt. If within the second quarter he did not make terms, all his goods and lands were to be delivered, the latter as if a gift of freedom, to the creditor, to hold to the use of the debt, as a substitute for sand, bread and water by the merchant. Precautions were taken against the debtor fraudulently making over his property. Lands given away by feu-fait subsequently to the recognizance were to be void. It is probable that the heirs did not bar the debt; for though the body of the heir could not be taken, his lands were answerable as much as during the lifetime of the debtor. The Jews were excluded from the benefits of the statute. (Stat. of Realm, i. 98.)

But there is another view of the case, which apparently shows that the above statute may be 'considered as contributing to extend the power of alienating land.' Any common creditor by judgment was empowered in the same session to take half the debtor's land in execution, 'but a merchant who had resorted to this security might have the whole.' He adds that 'a recognition acknowledged with the formalities [here] described was in after times called a statute merchant;' and 'a person who held lands in execution for payment of his debt, as hereby directed, was called only occasionally a creditor, or rather Adail. (Obs. on the More Ancient Statutes, p. 119) states that in 1536 an ordinance of Francis I. was issued, which very much resembled the statutes merchant, and shows, he says, 'the more ancient statute merchant.'

ADAIL is the Arabic name of a part of the eastern coast of Africa, and has been adopted by European geographers. Until lately it was applied to the country that surrounds the Bay of Tadjourah, which constitutes the most western corner of the Red Sea, in the month of Sept. 1500 S. lat. 9° 20', from the Bay of Tadjourah to the Strait of Bab-el-mandeb, but of late years it has been ascertained that it is applied to all the countries inhabited by a nation called by the Arabs Danidik: they call themselves Afaan. The name Adail, or rather Adai, is derived from Ad Alli, which is the name of one of the most famous tribes of the Danidik.

The Danidik tribes inhabit the coast from the Bay of Tadjourah to Cape Bab-el-mandeb, and from Bab-el-mandeb along the coast of the Abyssinian territory, for a distance of about 120 miles from the sea. As the highlands of Abyssinia gradually approach nearer to the shores of the Red Sea as they run further north, the territories possessed by the Danidik grow narrower and narrower.

Coast and Islands.—The length of the coast along the Red Sea is above 300 miles. In several places it is studded with rocky islands. With some few exceptions they belong to the same formation. Their surface consists of large fragments of coraline rocks mixed with sand, shells, and the indurated parts of mollusces. These islands do not in general rise more than 12 feet above the sea. In the dry season they appear to be quite bare of vegetation, but in the wet season, which lasts from June to April, the shrubs and trees are covered with leaves, and a scanty grass springs up in some tracts: a few mangroves preserve the moisture longer. No agriculture is carried on. Only a few of these islands are inhabited, and those only by the fishermen who live by their fisheries: many of them are used as pastures for goats, and some antelopes are met with. The largest of these islands is Dhalak. Between these islands and the mainland are several small harbours, but few of them are good; it is however remarkable that the island of Tadjourah, which is the most distant from the coast, has several harbours, even boisterous weather may be in the middle of the sea or along the coast of Arabia: thus the harbours generally afford shelter, especially to small vessels.

The adjacent coast resembles the islands in its formation. It consists of coral rocks rising abruptly 10 or 12 feet above the sea, but on the top it extends in a dead level. Opposite Massowah Bay this level is about two miles wide, but farther south somewhat wider. It is furrowed by numerous watercourses, in which during the rains an immense volume of water rushes down from the adjacent mountains; but when the rains have ceased the beds become dry, and in that state they remain for eight months. There are no springs, and the rain-water is preserved in tanks; but water may also be obtained by digging in the dry beds of the watercourses, where it is generally met with at a depth of 12 feet. The soil consists of some rocky fragments, and of sand and pebbles, and of a sort of soil which has no name, but is so sterile that the whole is left in its natural state, cultivation being limited to a few gardens in which hens (Lusonia inermis) is grown. Full-grown trees are only found along the rivers: in other parts there are only a few isolated mimosa and acacias, a coarse kind of saline plants, and aloe trees. Along the sea are isolated bushes of avicennia (Avicennia alba, Blum.) and tamariskas. Between the Bay of Massowah and Annesley Bay is Mount Takorah, which extends from 5000 to 10,000 feet above the sea. It is isolated, and its upper part is covered with large trees, but there are no springs at its base.

South of this mountain the level plain grows wider, being three miles across. There are dispersed over it a considerable number of conical hills, which rise from 200 to 300 feet above their base. In their vicinity the soil chiefly consists of decomposed lava, and is much more fertile than the other parts of the plain: trees however are wanting, and low bushes appear. A hot and dry season (from July to September) the temperature ranges between 86° and 92°, and in the afternoon it generally ranges five degrees higher. In this season the sky is rarely overcast; but in the beginning of October, when the rainy season on the table-land of Abyssinia is near its termination, the cloudy sky sometimes retards this season of the year, and makes fine grass. Camels, goats, and sheep are comparatively numerous. Cattle are not so common. Antelopes are numerous. Water is generally got by digging a few shallow holes in the surface.

It is a general opinion that the low tracts along both sides of the Red Sea are the hottest countries on the globe. This is also confirmed by the meteorological observations which were made by Rüppell at Massowah during eight months of the year 1831 (from December to April) the temperature ranged between 72°5 and 80° before sunrise, and between 82° and 88°5 at three o'clock in the afternoon. In the hot and dry season (from July to September) the temperature ranged between 86° and 92°, and in the afternoon it generally ranges five degrees higher. In this season the sky is rarely overcast; but in the beginning of October, when the rainy season on the table-land of Abyssinia is near its termination, the cloudy sky sometimes retards this season of the year, and makes fine grass. Camels, goats, and sheep are comparatively numerous. Cattle are not so common. Antelopes are numerous. Water is generally got by digging a few shallow holes in the surface.

Though this low tract produces hardly anything fit for use except fire-wood, the sea supplies substance and articles of commerce to many families. Pearls are found in some places, especially in the vicinity of Dhalak, and also turtle. Among the fishes are whales, probably the Physeter: three kinds of dolphins, of which the largest is a Phoecena; and the dugong, which last three hundred are annually taken by the fishermen of Dhalak.

Physical Geography.—The interior of Adail is only known along the routes which European travellers have followed in ascending from the table-land of Abyssinia. Those who have visited Tadjourah traversed the country south of the harbour of Massowah, and those who visited Shoa deplored from Tadjourah, and reached Ankobar by a southwestern road.

The acclivity by which the table-land of Tigris is ascended occupies a space varying between 30 and 40 miles in width. Its direction is nearly parallel to the sea-coast. The depressions, valleys, or ravines by which it is furrowed generally present the edge to the direction of the mountain mass, but at others they cut that edge obliquely, running from north to south. Near the low tract along the coast the rise is gradual, and the country at a distance of 25 to 35 miles altitude is green and covered with trees above the sea-level; but as it approaches the edge of the table-land the ascent is very steep, for within six or eight miles the rise of the rocky mass generally amounts to between 6000 and 7000 feet.

At the back of the low tract along the sea the rise of the country is very gradual, and the table-land is covered with depressions, in which the watercourses lie. The surface of this tract is sandy, and nearly without grass, but sprinkled with acacias and low bushes; it occupies about three miles in width, and is not inhabited. The junction of the low tract: its surface consists of low hills composed of black rock, and supplies tolerably good pasture in the rainy season. The depressions between them may be called valleys. In winter they are traversed by large torrents, and in summer there is always excellent water a few feet below the surface in the heads of the streams. These valleys are covered with

Vol. I. — F
bushes and a few trees, of which the acacia is most common. There are many small villages, which are inhabited by herdsmen. In approaching the base of the steeper declivity the rocky masses that enclose the valleys become much more elevated, but the same is not the case with the valleys themselves. The more elevated part of this tract is an inclined plain with a strongly undulating surface. In general the eminences are composed of volcanic matter: in some places lava is found, and at others the surface is covered with a salt efflorescence. The surface is stony; and in many parts there are groves of trees, and the upper country is covered with low and stunted thorn-trees. In the valleys there are acymares of considerable size and nalac bushes (Rhamnus nabal), which are of medicinal and pleasant use. Near the base of the steep ascent some of the valleys are contracted to ravines, but others widen into plains: such is the Valley of Modot, about 25 miles due west of Massowah, which is nearly three miles wide, and extends to a considerable distance from south-east to north-west along the base of the mountain-masses. In this valley, as in other parts of this region, a few spots are cultivated with durra (Holcus sorghum). Cattle are kept; and large quantities of butter are made and sent to Massowah, and thence to Arabia. Between the end of the dry season (from June to November), when the grass in the valleys is dried up, the cattle ascend the higher acclivities of the mountains, and even to the table-land of Tigré. Camael, mules, asses, sheep, and goats are abundant. This tract is the haunt of numerous wild animals: elephants are sometimes met with, which have descended from the table-land. Lions also sometimes make their appearance. There are numerous wolves, hyenas, lyncxes, leopards, foxes, wild hogs, several kinds of snakes among which are the cobras and the gazelle, and harriet. Among the birds are several kinds of parrots (Frimgilla paradisae) and pearl-fowls (Numida peloronoryncha).

The upper declivity of these rocky masses presents a succession of long and steep ascents and sloping terraces of moderate extent. The ravines by which they are intersected contain large trees. Some on of the terraces a little cultivation is carried on, and durra and barley are grown. In this region the crops of barley and durra are increased in abundance and size with the elevation of the mountains. Camael, cattle, and goats find abundant pasture. This region is inhabited by nomadic tribes.

This description applies to the caravan-road from Massowah to the village of Halai, situated on the top of the ascent on the table-land of Tigré, and this road has been followed until lately by all travellers to Abyssinia. It is called the road by the Pass of Tarasa, which name is applied to the highest pass in the Acclivity of the road. The Pass of Halai is 8628 feet above the sea-level; and a resting-place at the base of the steeper ascent, called Mahlo, is only about 2130 feet; but of later years it has been ascertained that there are in some places the two other passes are preferable, because the ascent is less steep. One lies north of the Tarasa Pass, and connects the village of Gara on the table-land with Massowah; and the other is south of the Tarasa Pass, and leads from the village of Tekunda (Degonta) down the declivity to Arboga and Massowah.

We pass to the southern extremity of Adal, to the caravan road which leads from Tashurah to Ankobar, the capital of Shoa. The country through which this road runs is a table-land of moderate elevation, and it may be considered as an intermediate terrace by which the highlands of Shoa are ascended. The surface exhibits a considerable variety. No portion of it is under cultivation; but, with the exception of a few parts, it is not arable. It supplies pasture all the year round; and at the end of the dry season, however, in May and June, it suffers from want of water.

A short distance from the shore on which the town of Tashurah is built, there is a cluster of hills of trachyte formation, the surface of which is covered with basalt. The base of Tashurah is 2000 feet above the sea. This group of hills is traversed by glens, through which a considerable volume of water runs during the rains, but very little is found at the end of the dry season. Between Tashurah and the summit of the hill the ascent is by sandy, deposits covering a stony substratum. Water is obtained from wells: it is pure, but has an unpleasant taste. Grass is scarce, and only goats are kept. There are only shrubs and shrub mimosas, with a few date-trees, near the villages. Of shrubs, melacca, juncus, and leopards are numerous, and various kinds of birds.

The Bay of Tashurah terminates in a shallow lagoon called Gubbat-el-Kharab. This lagoon approaches the base of a table-land covered with lava, which extends westward to the vicinity of Lake Assal. The road lies north of this table-land. It passes through low undulating hills covered with sparse vegetation, and is intersected by several branches of the river Killelu, which runs from the north-east, and about three miles wide. About one-third of its surface is covered with a sheet of salt, about half a foot thick, which resembles ice. The lake is shut in on the northern, western, and southern shores by ranges of high hills, among which is Mount Sivay, which is probably 1500 feet above the sea. On the eastern side is a bed of lava, which, as before mentioned, extends to the Gubbat-el-Kharab, and which contains several deep craters. It is supposed that at this point the lake was, at some remote period, connected with the bay of Tajurrah.

On the south-west of Bahr Assal is a hilly tract. The hills near the lake are precipitous and high, but farther on they are lower and rounded. This region, from Bahr Assal to the town of Gadage, more than 20 miles distant from the lake, is only 270 feet above the sea. The water in this tract is plentiful, but has a brackish taste. Grass is only found at a few spots at the end of the dry season. A few groves of doom palm-trees are found, with small cones, each in a distinct triangle. In the vicinity of Gadage, and lies between high hills running from south-east to north-west. The surface is partly composed of a hardened and cracked alluvial deposit, which is quite bare, and is partly covered with a thin soil overgrown with a jungle of acacia and a species of auburn.

After leaving this plain the country rises more rapidly. A few miles farther to the south-east it is 1200 feet above the sea-level. Further on the country preserves in general the same character as above, with a few changes. The table-land of the eastern part is described as the Tigré, and the western part is the semi-arid table-land of Tigre, which is situated about 670 feet above the sea. The climate at the eastern part of this table-land is generally of a warmer nature, and is distinguished by a peculiar kind of haze, which rises higher than the cloud and is always covered with grass. It terminates at the Wady Kullen, a large ravine bounded by basaltic cliffs from 800 to 900 feet high. At the end of the dry season water is only found in pools, but during the rains it is a large river, which receives the drainage of an extensive tract, and carries it to the Hawash river. The ravine is covered with bushes which are not found in other parts of the table-land, where the soil is very dry.

West of the Wady Kullen the table-land rises gradually till it attains an elevation of 2000 feet above the sea. The soil is here more volcanic, and improves in fertility; but the surface is more broken, and level plains are rarer and of less extent. The vegetation is composed of many kinds of wild plants, and is always covered with a thin layer of soil, which however is covered with a thick turf. But this region is almost destitute of water. On the west of this tract two lofty peaks rise from the plain. These are Mount Maita, which rises to 7054 feet above the sea, and Mount Asal, which attains 6589 feet, and is about 4000 feet above its base and Azolo still higher. They appear to stand in the centre of a volcanic tract, with which sheets of lava have descended on all sides to the plain, forming a field of volcanic matter about 30 miles in diameter. Mr. Kirk counted 21 of such cones. The surface of the lava appeared fresh and glossy. The vast plain adjacent to the
tract is covered with low shrub, and during the greater part of the year it is a sheet of water; but at the end of the dry season not a drop is found on it. As this region contains more wood than those nearer the sea, wild animals and game are more numerous here than in the plains of Ass, asses, wild hogs, zebras, guinea-fowls, quails, and spar-fowls.

South-west of this region the general level of the country is about 2500 feet above the sea. This is the most fertile portion of the country. The inhabitants of this region, being surrounded by all types of country, with the exception of the sea and the river, are far more numerous than the inhabitants of any other part of the country, and it is the centre of communication. The river Dawahi, which is supposed to have been navigated by the ancient Persians, is the most important stream in the country. The river is divided into two main branches, the western and the eastern, which are separated by a range of hills.

The country descends by several short terraces to the banks of the Dawahi river. The average level of the river is about 2500 feet above the sea. This river is divided into two main branches, the western and the eastern, which are separated by a range of hills.

tag it, but they knew little of any part, except the tract through which the caravan road from Massowah to Tigré lies. This road was also described by Bruce and Salt. In 1839 the English took possession of Aden in Arabia, to facilitate the passage of trade between Bombay and Suez, and this event soon led to a closer connection with the surrounding countries. In the same year the missionaries Isenberg and Krapf, having been obliged to leave Tigré, where they had resided for several years, went from Tadjoura to Ankobar, and, after passing through a desert, returned to Aden as European travellers. In 1841 Major Harris was sent by the British government to Shoa and succeeded in concluding a treaty of amity.

ADDITION. [SIDMOUTH, LORD.] ADEN, moss, AUSTRALIA, P. C. S.] ADELOCRINUS, a fossil genus of Crinoidea, from North Devon. (Phillips.)

ADELSBERG, a town not far from Lübeck, in the duchy of Holstein, consisting of five streets, and celebrated for the great caverns which are in its environs. There are two principal caverns, the cavern of Adelsberg, which is 1250 Vienna klafter, or about 7500 feet long, and the Magdalenä cavern, which has been explored for a length of 200 klafter, or about a third of a mile, of which three layers of the cavern are broken into huge square fragments, which in some places are heaped up by nature so as to resemble a Roman bridge. The most remarkable is the cavern of Adelsberg, the entrance of which, near the ruined castle of Adelsberg, is very narrow, but the cavern soon becomes wider, and forms several spacious grottoes which are from 60 to 80 feet high. Splendid stalactites hang down from the roofs and cover the walls, and present a beautiful appearance when seen by the light of torches. The Pink or Pinka, a little river, throws itself into the cavern, and as it forms several cascades the interior resounds with the uninterrupted noise of the waters. In the innermost corner of the cavern this river disappears through a narrow fissure in the rock, but continues its subterranean course for nearly eighty miles, till it appears again near Mallingrad-Kleinheisél, where it is called Unez. After having flowed through the valley of Planina it disappears once more in the caverns of Laoso, and comes again to the surface near the town of Laoso, which is called the Laibach. In those parts of this river which are subterranean, and especially in the cavern of Adelsberg, the Proteus is found. The Slavonian inhabitants of the country call it Bela Ribá, the Germans Weischen, both of which mean White Fish. It was first noticed by Laurenti in 1768, in his 'Synopsis Reptilium,' and was called the Proteus Anguìlius; but we owe the first and best scientific description of it to the learned Scapoli, a naturalist who paid particular attention to the various animal, botanical, and mineral phenomena of his native country Krajin. Sometimes the Proteus is found in the open parts of the river, though only when the water is high in consequence of heavy rains. [Proxerus, P. C.] Engravings on stone of the fish as it occurs in and near the mouth of the river, as well as of the Laibach, have been drawn and published by A. Schäfer and M. Schäferring, Leibach, 1839, fol.

(Count F. v. Hohenwart, Wegweiser für die Wanderer in den berühmten Adelsberges Grotte, Leibach, 1832; Neueste Conversations-Lexicon; Hamilton, Research in Ain Minor, vol. i. ch. 1.)

ADEN, a town and harbour on the southern shores of Arabia, in 12° 40' 10" N. lat. and 48° 10' 20" E. long. Being the principal port of the coast of Arabia, it was the most remarkable place, consisting of a small number of mud huts covered with mats, and containing about 600 inhabitants. Good water could be procured, but fire-wood, fruit, and vegetables were scarce, and fish was the staple food. In the year 1839 the English took possession of Aden, and burned the town and all its buildings. In recent years they have built a small fort upon it, and the place is now a British naval station. The town is situated at the extreme south of the island, and is surrounded by a mountainous tract, and in the environs of Aden, a village in Bohemia, on the frontier of this country and the silesian county of Graz, in a valley of the Riesen-Gebirge, or Giant Mountains; it lies in the circle of Königrätz. About twelve miles north-west of the town of Graz the traveller reaches the mountain of Reu-
scheuer, which forms the beginning of the rocky labyrinth. The summit of this mountain, or rather winding ridge, is cut perpendicularly like a wall to the depth of from six hundred to twelve hundred feet, and there are only a few paths by which a def. can ascend to the labyrinth below, which consists of masses of rock detached and laid one over another in all directions. Some are as large as moderate houses, and others have the size and shape of churches, pyramids, and similar buildings, or at least appear so to a lively imagination. One spring in particular and a day or two after heavy rain, when the centre of the labyrinth, the traveller passes by means of small crevices through a wall of sandstone of stupendous height, and he then enters a chaos of isolated columns, walls, towers, and other fragments of stone, that it may be said nothing has been left but the description, varying in height from 100 to 200 feet. Some of these rocks are rounded at the top by irregular curve-lines, but the lower parts of their sides are as perpendicular and straight as if they had been cut artificially. The most remarkable is that which is called 'Der Umgangskreuzstock,' or 'The inverted Sugarloaf,' which is surrounded by a great number of pillars, which, though most of them are only three or four feet in diameter at their bases, are as high as the most massive rocks, and appear like a group of lofty chimneys. The width of the paths or winding crevices between the rocks varies from two to twenty feet; they are in many places covered with deep and light sand produced by the fragments of the rocks which have been operated on by the atmosphere and rains; for this sandstone is very friable, and is often an unconsolidated agglomerate of quartzose sand. In the middle of the labyrinth there is a large opening, overhung by the surrounding rocks, covered with plants and grass; and here a great fall in the river, by a chain of cataracts, falls in a cascade from a fissure in the principal hill, on the top of which there stands a ruined Gothic castle. This remarkable spot is annually visited by many travellers, and has especially attracted the attention of geologists. It is generally supposed that the whole, which extends over many square miles, was originally one solid mass of sandstone, which has been split by volcanic action, and afterwards washed out by the waters. Similar groups, though comparatively little important, we would wish to mention, are found in the district of the Middle Weser, and especially in the district of Saxony Switzerland, where volcanic action has left many traces.

(From Langhans, *Das Adersbachische Steingebirge: Neuererer Mittheilungen—Lexicon; The European Magazine, August, 1822, contains an account which seems to be translated from the German of either Zöllner or Weisse; Erich und Graber, *Die Gebirge;* see also, *Geographic.*)

**ADJUDICATE.**—In the law of debtor and creditor in Scotland, is a process for attaching heritable or real property. It is applicable not merely to land and its accessories, but to all rights ' bearing a tract of future time,' as annuities, penalties, and fines; and in general has been extended to all such property as is the subject of bankruptcy or adjudication, as not attachable by the simpler process of arrest. The origin of this process of adjudication is to be found in a very ancient practice called Appraising, by which the debtor who refused to satisfy his creditor, either with money or land, might be compelled to part with so much of the land as the award of a jury found commensurate with the debt. This form was the object of legislation so early as the year 1660, when provision was made for compelling feuars to give the proper inducements to those who had acquired lands by such a title. The debtor who is compelled to part with his lands under the old appraising might redeem them within ten years; but it is said that this privilege was often defeated by delays, and, in order to obviate this abuse, by an act against judicial oppression, the genuine creditor being often defeated by the collusive proceedings of the debtor's friends and, on the other hand, a creditor to a mere nominal amount was enabled to compel the orifice of the orifice itself, that is, to make over to the creditor what had been adjudged to him by the court, to be redeemed within ten years, on payment of the debt, interest, &c. The latter is the alternative universally adopted in Scotland, and is adherent to the absolute property of the orifice at the end of the ten years without judicial interference, in an action of declarator of expiry of the legal,
in the Court of Session or in that of the Sheriff, in the same way as ordinary civil cases. The inferior Admiralty jurisdictions of Scotland were not abolished by the above act.

The constitution of the Court of Admiralty has been affected by two recent acts, the 3 & 4 Vict. c. 65 and c. 66. The first of these acts empowers the Dean of Arches to sit as assistant to in place of the Judge of the High Court of Admiralty, and admits to this court advocates, attorneys, and procurators. The second act vests the Court of Admiralty in all matters and proceedings with the right to make rules of court, and to enjoy all the privileges which pertain to the judges of the superior courts. The Court has power to adjudicate on claims for services and damages, to grant letters of administration to the next of kin of deceased but within the body of a county at the time when such services were rendered. It is empowered to direct issues on questions of fact arising in any suit to be tried before a judge of the superior court of common law, and to direct new trials, or grant or refuse them, subject to an appeal. The 3 & 4 Vict. c. 66, is an act for regulating the salaries and in some respects the duties of the judge and officers of the court. It fixes the salary of the judge at 4000L., with a retiring pension of 2000L. after fifteen years' service, or on becoming permanently disabled. It also prohibits the judge from sitting in parliament. The salary of the registrar is 1400L., without fees. In time of war, or in case of a great increase of business, the registrar's salary may be increased to 2000L. He performs his duties personally; but, if he is out of office, ill or absence, he neglects for two days to appoint a deputy, the judge is empowered to appoint one, and to fix his salary, which is to be paid out of the salary of the registrar. The Acts of 1782 and 1783 changed the commission of the judge. The temporary officers of the court are now separately to be appointed and paid. The fee for accounting to the Privy Council, for the payment of judgments, is 100L. The salary of the principal registrar is 250L., and that of the assistant, 100L. The fees for the court are carried to an account called the fee-fund, out of which all the officers are paid except the judge.

The business and fees of the Court of Admiralty are always much greater in time of war. From 1778 to 1792 Judge Marriott received 4600L. a year, the salary being 800L., and the fees averaging 3700L. a year. On the return of peace his salary was increased to 800L.; and his total income during the peace averaged 1800L. a year. In 1794 the salary of the principal registrar was raised to 250L. for all cases. But in the first ten years of the French revolutionary war, the income of Sir W. Scott averaged 5700L. a year, the salary being 2500L. and the fees 3200L. About a thousand cases a year were determined by the court during the war. (Evidence of Dr. Trench, Admiralty ibid. 1793; and of Sir David Atlay, ibid. 1833; reprinted in 1843, by order of the House of Commons.)

The Prerogative and Admiralty Courts were presided over by one judge on two occasions in the last century, from 1710 to 1714, and from 1722 to 1778. The Parliament Committee of 1833 recommended that the two judges of these courts should sit interchangeably, when occasion may require, either in one court or the other.

ADMISSIONS IN A SUIT are those facts or matters necessary to form a cause of action. They may be in the case of the plaintiff, or of the defend¬ant, in a suit in equity, the necessity of proving which is removed by the opposite party admitting them. Admissions are either, I. Upon the record, or II. By agreement between the parties.

1. The statements in a bill in equity, the truth or correctness of which is distinctly admitted in the answer, become thereby evidence for the plaintiff, and may be used by him to show the extent of the admissions made by the defendant. But when the defendant contains a statement or an instrument of a defeasance, will, and the defendant, while he admits it to be to the tenant and effect act forth in the bill, refers to the document itself for greater certainty, he has a right to insist upon the document itself be read in court. When a bill has been taken pro confesso against the defendant, under the stat. 1 Wm. IV. c. 36, it may be read in
ADMITTANCE. [Corypil, P.C.]

ADULTERATION (from the Latin Adulteratio) is the use of ingredients in the production of any article, which are cheaper and not so good, or which are not considered so desirable for which they are substituted. The sense of the Latin word is the same. (Flax, Act, xxi. 40.) This offence does not consider adulteration generally as an offence, but relies apparently on an evil of this nature being corrected by the discrimination and good sense of the public. The selling of articles most or partly adulterated under most local acts; and is also an offence at common law. In Paris, malpractices connected with the adulteration of food are investigated by the Conseil de Salut public, at the urging of the authority of the prefect of police. In this country, where the pecuniary interests of the manufacturer have been resorted to in order to prevent adulteration. It is not, however, heavy customs or excise-duites alone which encourage adulteration, for the difference in price between the genuine and the spurious article, when both are free from taxation, presents great inducement to the practice. The following is an abstract of the law respecting the adulteration of some of the principal articles of revenue:

Tobacco-manufacturers are liable to a penalty of 500l. for having in their possession sugar, treacle, molasses, honey, commings or roots of malt, ground or unground roasted grain, ground or unground chicory, lime, umbre, oche, or other earths, sea-weed, ground or powdered wood, moss or weeds, and any manures, or mixtures of manures, or grains (manures or plants), respectively, or any substance or material, syrup, liquid, or preparation, matter, or thing, to be used or capable of being used as a substitute for, or to increase the weight of, tobacco or snuff; or to preach counterfeit tobacco or snuff, or who shall sell or deliver such articles to any tobacco-manufacturer, is also liable to a penalty of 500l. (§ 8). The penalty for actually adulterating tobacco or snuff is 500l. (§ 18), and for suffering, knowingly, or by neglect, or connivance, or otherwise, an adulteration which resembles tobacco or snuff, or who shall sell or deliver such articles to any tobacco-manufacturer, is also liable to a penalty of 500l. (§ 8). The penalty for actually adulterating tobacco or snuff is 500l. (§ 18), and for suffering, knowingly, or by neglect, or connivance, or otherwise, an adulteration which resembles tobacco or snuff, or who shall sell or deliver such articles to any tobacco-manufacturer, is also liable to a penalty of 500l. (§ 8).

The ingredients used in the adulteration of beer are enumerated in the following list of articles which brewers or dealers and retailers in ale and beer are prohibited from having in their possession under a penalty of 500l. (66 Geo. III. c. 58, § 2). These articles—molasses, bran, mustard, quassia, cocculus Indica, grains of Paradise, Guinea pepper, and opium—are prohibited. They are used either as substitutes for hops or to give a colour to the liquor in imitation of that which it would receive from the use of the genuine article. The householder is guilty of the same act a penalty of 500l. is imposed upon any chemist, druggist, or other person, who shall sell the articles mentioned in § 2 to any brewer or dealer in beer. The penalties against the former applies in all cases where dealers in beer or other drinks are found in possession. Under 1 Wm. IV. c. 64, and 4 & 5 Wm. IV. c. 85, which acts also contain special provisions against adulteration applicable to this particular class of dealers; and the licence also prohibits the sale of ale, beer, and porter, made otherwise than from malt and hops; or adulterated with drugs; or fraudulently diluted, adulterated, or deteriorated.

Tea, another important article of revenue, is protected from adulteration by several statutes. The act 11 Geo. I. c. 30, § 6, renders a person dealing to a penalty of 100l. who shall counterfeit, adulterate, alter, fabricate, or manufacture any tea, or shall mix with tea any leaves other than leaves of tea (§ 5). Under 4 Geo. IV. c. 14, tea-dealers who dye, fabricate, or manufacture, licenee-leaves, the leaves of tea that have been used, or any other leaves in imitation of tea; or shall use terra japonica, sugar, molasses, clay, wood, or other ingredients, to colour or dye such leaves; or shall sell or have in their possession such adulterated tea, is liable to a penalty of 500l. for every pound of such adulterated tea found in their possession (§ 11). The 17 Geo. III. c. 29, also prohibits adulteration of tea (§ 1).

The adulteration of coffee and cocoa is punished with heavy penalties under 48 Geo. III. c. 20, who deal in, or manufacture, or has in his possession, or who shall sell or give, sensitized, scorch'd, or roasted peas, beans, grains, or other grain or vegetable substance prepared as substitutes for coffee or cocoa, is liable to a penalty of 100l. (§ 5). The object of § 5 of 11 Geo. IV. c. 30, is similar. Chicory has been very extensively used in the adulteration of coffee in this country. This root,
which possesses a bitter and aromatic flavour, came into use on the Continent in consequence of Bonaparte's decrees excluding colonial produce. Coffee with which a fourth or a fifth part of chicory has been mixed is by some persons preferred as a beverage to coffee alone; but in England it is used to adulterate coffee in the proportion of one-half. The Excise has for some time permitted the mixture of chicory with coffee. In 1829 a duty was laid on chicory, and this duty has been increased. But this has also alliterated that the importation of chicory into England is also grown in England, and to prevent fraud it will be necessary to place the cultivation under some restriction, or perhaps, as in the case of tobacco, to prohibit its being done together.

The manufacturer, possessor, or seller of adulterated pepper is liable to a penalty of 100l. (59 Geo. III. c. 53, § 22). The act 9 Geo. IV. c. 44, § 4, extends this provision to Ireland.

The important article of bread there are prohibitions against adulteration, though they are probably of very little practical importance. The act 6 & 7 Wm. IV. c. 37, which repealed the several acts then in force relating to bread sold beyond the city and liberties of London, and ten miles of the Royal Exchange, was also intended to prevent the adulteration of flour, meal, and bread beyond these limits. No other ingredient is to be used in making bread for sale except flour or meal of wheat, barley, rye, oats, buckwheat, Indian corn, or potatoes, and not exceeding in weight one-half of the flour or meal by which they are calculated. There is a penalty for a period not exceeding six months; and the names of the offenders are to be published in a local newspaper (§ 8). Adulterating corn, meal, or flour, or selling flour of one sort of corn as flour of another sort, subjects the offender to a penalty not exceeding 20l. and not less than 5l. (§ 9). The premises of bakers may be searched, and if ingredients for adulterating meal or flour be found, the penalty for the first offence is 10l. and not less than 40s.; for the second offence 5l., and for every subsequent offence half the amount of the fines of the offenders are to be published in the newspapers (§ 12). There are penalties for obstructing search (§ 13).

Any miller, mealman, or baker acting as a justice under this statute incurs a penalty of 100l. (§ 15).

The above act did not apply to Ireland, where the baking trade was regulated by an act (2 Wm. IV. c. 31), the first clause of which, relating to the ingredients to be used, was similar to the English act just quoted. In 1836 another act was passed (1 Vict. c. 28), which repealed all former acts relating to the sale of bread in Ireland. The preamble recited that the act 6 & 7 Wm. IV. c. 37, had been found beneficial in Great Britain; and the clauses respecting adulteration are practically the same in the English act.

The several acts for regulating the making of bread within ten miles of the Royal Exchange (which district is excluded from the operation of 6 & 7 Wm. IV.) were consolidated by the act 9 Geo. IV. c. 106. Under this act any baker who uses alum, or any other unhomogeneous ingredient, is liable to the penalties mentioned in § 12 of 6 & 7 Wm. IV. c. 37. Any ingredient or mixture found within the house, mill, stall, shop, &c. of any miller, mealman, or baker, and which shall appear to have been placed there for the purpose of adulteration, renders him liable to similar penalties.

Other articles besides those which have been mentioned are adulterated to a great extent, and there is scarcely an article, from arrow-root to guano, which escapes; but perhaps the result is not so great as it might have been had it not escaped the notice of those who profit by it, who are less likely to be imposed upon when depending on the exercise of their own discrimination, than if a commission of public functionaries were appointed, whose duty it would be to investigate and detect the presumption of adulteration. The interference of the government in this country with the practice of adulteration, except in the case of bread and drugs [Apotheics' Company, P. 33], has hitherto had no other object than the improvement of the revenue.

Adulteration and the deceitful making up of commodities appear to have frequently attracted the attention of the legislature in the sixteenth century, and several acts were passed for the prevention of it. Thus the act 20 Eliz. c. 8, prohibits under penalties the practice of mixing bees-wax with resin, tallow, tarpine, or other spurious ingredient. The following acts have reference chiefly to frauds in the making up of various manufactured products:—3 Hen. VIII. c. 6; 21 Hen. VIII. c. 17; 1 Eliz. c. 12; 3 & 4 Edw. VI. c. 2; 5 & 6 Edw. VI. c. 6; 5 & 6 Edw. VI. c. 28.
AETH

published by M. Havy in 1787, under the title 'Exposition de la Théorie de l'Electricité.'

Aetius discovered the means of changing a plate of air with electricity, when it is confined between two boards. He appears to have directed his attention to mechanical subjects; for he discovered that the hands and feet, when pressed against the poles of a Leyden jar, in electrifying them, the sum of the forces, decomposed in the direction of the arms, is a maximum.

(Biographie Universelle. The brief notices of the discoveries of Aetius are taken from the works named above.)

Aethanol. A very valuable liquid, as it is a non-poisonous ester of alcohol. The methods of preparing alcohol are there described. Its offensive odour is caused by the concentration of reflected or refracted rays at the angles where they appear to be suspended in the air.

The images which are caused by the reflection of light in the strata of a mirror, are merely third grade, having no objectives. When these strata of the mirror, or other objects, differ considerably in density from the strata above them, have been described under MIRAGE, P. C., and it is intended here to mention only those which are perceived on looking in or towards a concave mirror.

If an object be placed, or if a spectator place himself, directly in front of such a mirror, at a greater distance from it than the centre of its curvature, the penulous light diverging from points on the surface of the object, or from that part of the spectator's person which is turned towards the mirror and is not very far from its axis, will, after reflection, converge to corresponding points between the object and spectator and the mirror, and will constitute an inverted image of either. Now, let the spectator be himself the object; then the rays in each pencil constituting the image are refracted, and if directed inwards in a divergent state on his eye, will produce vision of the image; but those which enter the eye being in this situation few in number, and the eye not being capable of making the reflection, this impression if that which we usually perceive faint and indistinct: in those circumstances also it usually appears to be within or behind the mirror.

But, as the spectator approaches the mirror, the reflected rays which form the image converge less rapidly, and meet at a greater distance from the mirror in its front; the eye at the same time, being nearer the image, receives pencils which are reflected from parts of the mirror at greater distances from the axis, so that the image appears both greater and more distinctly. The observer, and the diameter of the image of the spectator will be seen hanging in the air, in an inverted position, between himself and the mirror.

If, while the spectator is yet farther from the mirror than the centre of curvature, he advance his hand towards the mirror, the hand of the image will seem to advance to meet it; and at a certain place, which is the centre of the mirror's curvature, since there the rays in the pencils which proceed from the hand will be reflected back in a certain line, the hand will seem to be held there. In this position the inverted image of the spectator will be very distinctly seen between the mirror and his hand.

The spectator now advances towards the centre, the image will advance to meet him, but it will become indistinct, and at the greater distance, and on the concave side of the mirror towards the mirror, the reflected pencils will converge to points beyond the centre in the opposite direction, that is, behind the spectator, and the rays of the pencils will enter the eye before they can unite to form a distinct image; the spectator will perceive the reflection of himself in the mirror in an erect position; and the figure will become more distinct as he approaches nearer to the mirror, since the reflected rays in each pencil approach nearer to parallelism, and become equal to the rays from the pencils, or midway between the mirror and its centre of curvature.

AETHERS. The most common of those, with the methods of preparing them, have been previously described in P. C. vol. I. and those, which, though perhaps now unknown, are useful to those who desire to have them, the first to be treated of, taking a general view of the modes of action on the human system, is sulphur ether, which is always understood to be the one intended. It is prepared by the German chemists and therapists designate them sensatia, a term liable to cause them to be confounded with bitumen. Others present the most perfect examples of volatile stimulants, being unequalled for rapidity of action, when immediately after the administration, the effects are immediate, and must be imparted to the muscular system, especially the involuntary muscles, by augmenting the nervous power, and by quickening its development. Whether they effect this by a direct impression on the nerves, or by previous absorption into the circulation, it is very difficult to determine, since most of them are absorbed so rapidly, as almost instantly to mix with the circulating mass. There are two greatest resemblance to alcoholic stimulants; but are distinguished by more instantaneous effects. These however are more transient, and a more frequent repetition of the dose is therefore required. Fatal results are less likely to follow from large doses of ethers of alcohol, than from spirits, which may be accounted for by the excess being more specially thrown out of the system, especially by pulmonary and in some degree by cutaneous exhalations; for the more highly carbonized spirits is the more readily converted. It furnishes the proper guide for the treatment of cases of poisoning by them, viz. placing the patient where he may respire as pure air as possible, and in the light, carrying on the administration of a needful, occasionally dashing cold water on the face and temples, and stopping of respiration or cupping. Transmitting a galvanic current of a moderate force along the eighth pair of nerves is often beneficial. Perseverance in the use of these means for hours is frequently successful. Sulphuric ether is the most powerful of atherial preparations, and therefore of diffusible stimulants. It is distinguished from the others likewise by having less secondary effects upon the system. Hence it is more employed for its primary effects than for both primary and secondary effects. It is of a peculiar, strong, penetrating, rather agreeable odour; the taste is at first cool, afterwards hot, leaving a feeling of dryness in the mouth and throat. Its volatility is very great, and though it does not excite redness of the face, it produces a similar effect; the respiration, which is being quickly changed into vapour by the heat of that organ, causes contraction of its muscular coat, and expulsion of gas, thus acting as a carminative, or it produces most painful discomfiture from the effort of the muscles of respiration, and is followed by slight cerebral excitement, and even a feeling similar to intoxication may be experienced, which however soon passes off, without leaving any marked depression; though a disposition to sleep, and sometimes tendency to give way to delirium. If the patient be placed in a very cool and air free common channel by which it is eliminated; this ether having less influence on the kidneys than other than the other. If spasm, irregular action, or debility of the organs of digestion, which usually follow, is treated by antispasmodic, digestion, and consideration, these generally disappear speedily, or are alleviated by its use. Hence it ranks as an antispasmodic of the highest kind. It is therefore resorted to in all cases of imminent danger, from difficulty of breathing, colic, delirium, and deep depression, such as occur in cholera, tetanus, or the later stages of fever. In relieving paroxysms of asthma it is unrivalled, and may be inhaled along with the vapour of warm water, or by being dropped on a portion of the skin and held between the fingers. Its very effect on the system, that the dose required greatly to be increased. So much as two ounces have been taken by an adult in twenty-four hours. This is hazardous, and the necessity for it may be diminished by administering the sulphuric ether with the aid of the other stimulants. Little known or used in this country, are found very effectual by the German, French, and American practitioners. An increase of our atherial preparations would be a valuable accession to our curative agents. Economy and physiology alike recommend this proceeding. The great solvent power of sulphuric ether renders it an eligible menstruum for the administration of a variety of articles; by these its own powers are heightened. It has also been attempted to take advantage of its power in this respect, by employing it in cases of bilious calculi, not merely to alleviate the agonizing pain, but from a belief that it would dissolve the calculus, and so lessen its bulk. Oil of turpentine is a good addition. It has also been employed for the purpose of discharging the notion that the volatilized ether would greatly annoy the worm, and allow it to be easily removed by a dose of castor oil or other purgative. This is not free from inconvenience and even danger to the feebile persons with whom it is employed. The use of ethers of power is much increased by adding tincture of opium, or a solution of the hydrochlorate of morphia. This combination furnishes the most effectual means of warding off a paroxysm of hysteric fits or epilepsy, if administered promptly. This is especially the object of great moment, as every fit, if allowed to take place, predisposes to a recurrence of them. Externally, ether is applied to the temples to relieve nervous headaches; and also over hernial tumours, in order that by the local application on its evaporation the hernia may contract and be reduced: a

P. C. S. No. 6
ortion of thin oiled silk should lie interposed between the aether and the skin.

The marvellous copaiba tree is a rare tree found in the tropics, prized for its chemical properties as a solvent of various substances than with its medicinal properties. Timo however resolves it, particularly if kept in the light, into acetic acid and alcohol. It is found in the semi-tropical region of the earth, often in an obscure place. The spirit of sulphuric ether is only a weaker form, with some aetherial oil, of the pure ether.

Chloric ether is also markedly diuretic. It is a most valuable analgesic in the sinking stages of fevers, and much commended by Dr. Copland (see his Dictionary, vol. i. p. 927) and Charcot, physican.

Acetic ether is a very agreeable stimulant, possessing a grateful odour, resembling Rhine-wine, and a cooling, aromatic, somewhat bittersweet taste. Its action is similar to that of the other aethers, and though not so potent, it is more agreeable to take. Its long continued use however oppresses the digestive organs. Nevertheless it deserves to be employed in acme fevers, its action on the skin renders it very useful for its anti-septic and antiperspirant properties. In very serviceable; also in aphryxia. In some local affections it is of great utility applied in the form of vapour, such as some forms of deafness. (See Fletcher On the Ear.)

Sulphuric ether is a valuable restorative in the paralytic stage of fever.

AESHINA. In this recent genus of Libellulide Mr. Strickland ranks a fossil insect from the lias of Warwickshire.

AETHYPHILUM, a fossil genus of plants from the keuper. (Brongniart.)

AETION (Aetion), a celebrated Greek painter, and, according to Lucian, one of the best ancient colourists; that writer mentions Aetion, Apelles, Euphranor, and Polygnotus as the most successful of the ancient Greek painters in the mixing and laying on of colours. Aetion's exact time is uncertain, although from the manner in which he is mentioned by Lucian, notwithstanding the names he is associated with, he lived probably in Lucian's own time, or at most very shortly before him. He speaks of him as the most distinguished painter of his time. Ilyas, a second-rate painter, once pleaded him in the marriage of Alexander and Roxana, which the painter exhibited at the Olympic games, and which pleased Proxenida, one of the judges, so much, that he gave Aetion his daughter in marriage. 'It cannot be asked,' says Lucian, 'what was there so marvellous in that painting, as should induce a man of such high rank to reward the painter, who was for a stranger, by bestowing on him his daughter?' The picture is still in Italy, and I am able to speak of it from personal inspection. It is a picture of extremely magnificent size, in a noble hall-chamber with a nuptial bed. In it is seen sitting Roxana, the most beautiful virgin that can be conceived. Her eyes are modestly fixed on the ground before Alexander, standing near her. The picture is of such a size, that one cannot at a distance make out all of her, which, above of her behind her lift up the bridal veil from her forehead, and shows it to the bridegroom. Another, in the attitude of a slave, is officiously employed in drawing off her shoes, that she may no longer be detained from lying down. A third, called of Alexander's race, paints him with all his weight towards Roxana. The king presents the maiden with a crown, and beside him stands Hephæstus as a bridegroom, holding a lighted torch in his hand, supported by a wonderfully fine youth, whom I guess to represent the god of marriage, for the work of it is well performed: the two figures are drawn as several more Cupids, playing with the arms of Alexander.

Two of them carry his spear, and seem almost overburdened with the weight of it. Another couple take his mantle, which he spreads upon it, tracing it along by the handles. Another creeps backwards into the coat of mail, where he seems to lurk in order to frighten the two little porters as they come on. 'These collateral incidents,' continues Lucian, 'are by no means the mere wantonness of the artist's fancy, but a wantonness in the means of the marriage, which is on the ground of the marriage of the goddess, and the marital disposition of the bridegroom, and that his love for Roxana had not effaced his passion for arms and military glory.' (Tooke's Translation.)

From this description Raphael is said to have made a design, of which there are duplicates or copies, and it was executed in fresco, in the so-called Villa of Raphael, in the garden of the Villa Borghese at Rome; but the composition is puerile, and does not at all merit the praises which Lucian has given it. It was given several times engraved and etched, or by J. Caraglio, Volpato, and others.

Lucian in the above description remarks, that he resembles a fine youth to represent the god of marriage, as the sacred ostensores. It is a kind ofcombe, which was prevalent among the Greeks, of attaching the names in their pictures to the figures represented; the names in most cases were probably written below the feet of the figure. In the pictures on canvas we find the name sometimes written on the figure, but the practice was not universal. In this case, from Lucian's remark, it would seem that some of the figures had names attached to them, as he speaks of the other characters with certainty, and guesses only at the god of marriage, because the name was not attached. It was a practice, however, seldom if at all had recourse to in later times, and in care of its employment the name was probably so placed as not to disturb the pictorial effect. Sometimes sentences were inscribed on pictures, as for instance Zeno wrote upon his picture of Helen three lines from Homer, celebrating her extraordinary beauty. (Ibid, iii. 156-158; Valerius Maximus, iii. 7, § 3.) There are similar examples on works of the middle ages, and also of much later times: inscriptions below names are frequent.

The circumstance that Pliny has not mentioned Aetion is an additional reason for concluding that he lived about Lucian's own time, or in the early half of the second century of our era, subsequent to Pliny. Another circumstance that the Echion of Pliny and Cicero is the Aetion of Lucian, especially as the former was celebrated for a picture of a bride distinguished for the modesty of her expression; but this implies a great blunder in Lucian, who speaks of him as a painter of his own time, and there is no sufficient reason for such a supposition.

(Lucian, Herodotus or Aetion, De Mercede Conducatis, 42, and Imag. 7; Pliny, Hist. Nat. xxv. 10. 36; Cicero, Brucius, 18; Parad. v. 2.)

AETHIUS (Aetius), of Amida in Mesopotamia, a Greek writer on medicine, who probably lived about the end of the fifth and the beginning of the sixth century of our era, as we may infer from the persons whom he mentions in his work. He studied medicine at Alexandria, then the seat of the most celebrated practitioners in that city, and he exhibited pieces in the form of a treatise on the marriage of Alexander and Roxana, which the painter exhibited at the Olympic games, and which pleased Proxenida, one of the judges, so much, that he gave Aetion his daughter in marriage. 'It cannot be asked,' says Lucian, 'what was there so marvellous in that painting, as should induce a man of such high rank to reward the painter, who was for a stranger, by bestowing on him his daughter?' The picture is still in Italy, and I am able to speak of it from personal inspection. It is a picture of extremely magnificent size, in a noble hall-chamber with a nuptial bed. In it is seen sitting Roxana, the most beautiful virgin that can be conceived. Her eyes are modestly fixed on the ground before Alexander, standing near her. The picture is of such a size, that one cannot at a distance make out all of her, which, above of her behind her lift up the bridal veil from her forehead, and shows it to the bridegroom. Another, in the attitude of
Hindoo-coooh do not run parallel, but converge, they unite in one mountain-mass between 70° and 68° E. long. The country included by these two ranges is called Kafiristan. It includes the northern declivity of the Western Himalaya mountains, the southern portion of the Pamir. What is seen from the plains at their base, these mountains rise in terraces; the northern and higher mountain overtopping the southern and lower, and thus at some places four ridges are parallel. The valley of the Indus joins the Pamir. A considerable portion of these declivities is under cultivation, and the term used to an elevation of 10,000 feet above the sea-level, is overgrown with high forest-trees; near the base and to an elevation of 4500 feet above the sea the forests consist of balouit, a species of oak, but above that line they are mixed with saltoon, a species of olive. The last-mentioned species forms the chief if not the only forest-tree as high as 6500 feet, where it is gradually replaced by the deodars, a species of fir. The Himalaya mountains are the most extensive in Afghanistan.

Near 70° 12° E. long. and 37° 55' N. lat., where the Himalaya already seem to be connected with the Hindoo-coooh, the nature of the mountains changes suddenly. The higher ranges indeed do not end in a plain, but divide into a large number of detached peaks, and the sides of the mountains are destitute of trees. They are almost entirely devoid of soil, and the rocks project in every direction, and the intervening places are strewn with angular débris, very little covered. Some of these are not cultivated, and sustain nothing but arid and thorny bushes, which almost invariably stand alone. Such is the nature of the Hindoo-coooh as far west as 68° E. long., where that high summit or rather mountain-pass occurs which properly and has given its name to the range, and rises to more than 15,000 feet above the sea-level. There are however many other peaks which are always covered with snow. Some of the valleys included in this range are very populous. The best known is that of Panchshir, through which one of the routes passes which lead from Kabool to Kundus, and which at the upper end of the valley traverses a mountain-pass, 13,200 feet above the sea, called the mountain-pass of Khaawack. The valleys of Panchshir, which are numerous, are very wide, and in most places about a mile and a half wide; no part exceeds twice that breadth. The upper part of it, about 25 miles, is not inhabited, probably on account of the severity of the cold in winter, but in the lower part there are seven villages inhabited by Turkomans. One of these is called Khaawack, it is a small village, and is a seat of particular importance, for cultivation only to a small extent, but every foot of it is cultivated. The orchards and the mulberry plantations constitute the wealth of its inhabitants; the mulberries are dried, and yield a good flour, which forms the principal food of the people. Another road, which traverses the Hindoo-coooh and leads to the plains of the Oxus, lies farther west, and runs through a similar valley watered by the river Parwan. The mountain-masses are at least as high as the Pass of Khaawack, about 70° E. long.

The high summit of the Hindoo-coooh above mentioned terminates the range just described. At this point the range changes its direction, running nearly due south between 36° and 34° 30' N. lat., and deserts near the sea. This portion of the range goes by the name of the Mountains of Paghman. It consists of two parallel ridges, and includes a valley more than 10 miles in width, which has a hilly surface, and seldom sinks so low as 10,000 feet above the sea. This valley is used partly as pasturage, partly for cultivation; but it is the favourite resort of the nomadic tribes in its vicinity in summer time, on account of its excellent pastures. The two ranges which enclose the valley are from 3000 to 5000 feet higher than the plains near its head; but in summer, several passes lead over them to the valley of Bameeheen, which is west of the western range and only 8000 feet above the sea. The best known of these passes are those of Oghourund, of Erak, which attains 13,800 feet, and that of Kulloo, which is 12,841 feet above the sea-level.

The Koh-i-Baba range may be considered the commen-
ment of the Paropamisus; north of it lies the mountain-region of the Hazar. The Koh-i-Baba is not a mountain-region, but a single range, which rises suddenly where the Pughismian mountains terminate, and then runs due east. At its eastern extremity it presents an immense mass of rocks, overtopped by three snow-clad peaks. The great mass attains an elevation of about 14,000 feet above the sea, and the peaks rise about 1500 to 1600 feet higher. Patches of snow are found on this range, which extends 130 miles from the eastern end of the Koh-i-Baba. These mountains are barren, for the rocky masses have no covering except angular fragments of rocks which cover the declivities.

To the north and west of the Koh-i-Baba are the mountain-regions of Panjshur and Hazar, and hence the Koh-i-Bala, the whole country between 34° and 36° N. lat. and between 68° and 83° E. long., comprising an area of nearly 50,000 square miles, equal to the extent of England without Wales. The eastern part, or that which is north of the Koh-i-Bala, and is in possession of the Hazar tribes, is the more elevated. Its surface presents a succession of high mountains with rather gentle slopes, which are traversed by numerous open valleys of moderate width. The declivities of the mountains are frequently covered with a soft soil composed of grass, and various shrubs and herbs, but is destitute of trees. Some of the higher valleys can also be used only as pasturage; in the lower valleys barley is cultivated, and in the long narrow valleys, along the coast, wheat, barley, and rice are obtained.

The domestic animals are horses of a small breed, cattle, and sheep, but as the country is so high the climate is very severe, and the Hazar tribes are obliged to cut great quantities of grass for their sheep, which, during three months of the winter, usually sleep under the same roof with their master. The general level of this country appears to be about 10,000 feet above that of the sea.

The mountain-region of the Emainak does not materially differ from that of the Hazar, except that the mountains are less elevated: their general level does not much exceed 9000 feet above the sea. The valleys also sink deeper, and are firmer for cultivation, which is also carried on to a greater extent, but even here the produce of the domestic animals constitutes the wealth of the population. They are not obliged to procure winter fodder for their sheep and cattle in such large quantities as the Hazaras, for in the valleys, to which they return in autumn from the mountains, great quantities of pasturage are found in sufficient abundance. In summer, this region, as well as in the country of the Hazaras, the pastures are so abundant, that several tribes of Doornanees, which inhabit the Zemin Dwar, or the country between these mountain-ranges and the river Helmand, bring their flocks to these pastures; it is for this reason that the rice-grains in that season the grass in their own countries is burnt up.

II. The Valley of the Kabul River.—This valley lies along the southern base of the eastern portion of the mountain-region; just descented, and beginning on the west at the foot of the Pughismian mountains, and stretching eastward to the banks of the Indus river, through a space measuring nearly 200 miles in a straight line. At its western extremity the valley is about 10,000 feet above sea level; but where it terminates on the Indus it does not exceed 750 feet.

The southern boundary of the valley is formed by an uninterrupted chain of heights varying in elevation. This chain is not connected by any ridge with the Mountains of Pughism, but is generally separated from them by a narrow valley called the river Mydan, which is 7747 feet above the sea-level, and is well cultivated, and covered with orchards and fields. Through his plain the road runs from Kabul to Ghuznee and Kandah.

On the east of the road rise some hills of moderate elevation, which at first are rather loose, but unite in a continua-

tion chain. Baber describes them as low, with little grass, bad water, and not a tree on them; and adds that in the whole world he had not seen such a dismal-looking hill-country. This is generally covered with mountainous vegetation, that consists of great metallic riches. During the British occupation of the country it was discovered that extensive beds of very rich copper-ore exist in many places, though the natives only work them occasionally. These hills are separated by about 20 miles from Mydan, at Tazen, where they rise higher and are covered with trees. East of 69° E. long, these mountains attain their greatest elevation in the Sufad-Koh, or White Mountain, which is covered with snow all the year round. This elevated rocky mass appears to extend 30 or 40 miles from west to east, and perhaps half as much from north to south. Its summit rises about 16,000 feet above the sea.

The declivities of this mountain, to an elevation of more than 10,000 feet, are covered with forests, especially the species of deodar; and near the base are plantations of fun-
trees. In some places they are cultivated, and the pasture-
lands are divided by a number of small streams, which descend in numerous streams, which preserve a considerable volume of water all the year round, an inestimable advantage in a country which has a dry air, and where in summer the largest springs are frequently dried up, as they are trickling down to mere brooks. The high mountains appear to termi-
nate near 70° E. long., and the range of lower mountains which runs hence eastward to the Indus is called the Kyber-Tir range. Near the Sufad-Koh these heights certainly rise to 10,000 feet; but they grow lower farther to the east, and where they terminate on the Indies with a precipitous de-
civity they can only be called high hills. This portion of the range descends with rather rapid slopes towards the north, and its sides in many places are marked by a scanty grass, except after the great rains in July and Au-
gust, when the grass is abundant. Cultivation is limited here, but its tops, which present plains of moderate extent, have a deep soil, which yields gold crops where it can be irrigated. The road descends between ridges, in some places mounting to 4000 feet west of the town of Kabool, drains the Mydan valley, and passes through the town of Kabool, where it is an insignificant stream. Below the town it is joined by two more considerable streams, the Helmand, which descends from the mountains west of the town of Logur, and the Yoor, which descends from the most eastern mountain-region, and enters it from a small chain of Kabool from that of Jellalabad, and in this part of its course the river descends about 4000 feet in a space of 30 miles in a straight line, and descends with rapidity; there are oaks in the banks of the river. Two or three miles below Jellalabad the Kabool is joined by the large river which drains the Koonur valley in the Himalaya range, and is generally called Koonur. The Kabool then begins to descend more gradually, and in this part it enters another mountainous tract, and it emerges from it at Muebarr in the Plain of Peshawur, or Peshawar, where its current is very moderate. A short distance below Muebarr it divides into two branches: the lesser, or Shulamur river, passes only four miles north of Peshawur, and unites, 5 miles in a straight line from the point of division, with the Hadezy, or other branch. After a course of thirty-five miles more it enters the Indus. The island formed by the two rivers near Jellalabad and Peshawur may be traversed in 12 hours; and by land is not less than 100 miles. The conveyance of goods on such rafts holds out a prospect of enlarging the navigability of the Indus river itself. No river vessels can ascend this in-
terested river farther than Kalabagh, the current is too weak to transport goods, and the rapids would experience no difficulty in proceeding to Kalabagh, and there discharging their loads into the boats which navigate the Indus. The Kabool river is lowest in the winter, notwithstanding the fact that it enters the Indus in that month, so that place and Attock become too rapid. But the rafts would experience no difficulty in proceeding to Kalabagh, and there discharging their loads into the boats which navigate the Indus. The valley of the river is divided by the high plateaus, which are divided from each other by two extensive moun-
tain-regions. The three basins receive their names from the principal towns, and are called, from east to west, Kabool, Jellalabad, and Peshawur. In their upper parts, called the mountain-regions, they are separated by the river, which is called Lattabund, and the eastern Kyber, from the two most frequented passes which lie across them.
The Basin of Kabul extends about 36 miles from west to east, and from 8 to 16 miles in the opposite direction. It is divided by two ridges of hills into three plains. The town of Kabul is built at the base of a ridge of hills which runs across the plain from east to west, and at the height which the Kabul river passes by a gorge. From its highest summit, called Takt-i-Shat, at the foot of which Kabul stands, the whole ridge has obtained the same name. That portion of the plain which lies west of the Takt-i-Shat ridge is called Charkh-i-Shat, and that portion which lies east of the ridge, and which, for the sake of clearness, we have called the civil or agricultural district of Kabul, is called Kang-i-Shat. This is a very fertile tract, presenting one continuous mass of verdure, and a succession of extensive orchards and meadows, between which a great number of villages are dispersed; they are watered by the Kabul river, raised about two or three months by rows of poplar and willow. Fruit is so abundant that the poorer people live entirely on it for many months of the year, though corn is raised to a considerable amount.

The eastern and wider portion of the basin is divided by another ridge of heights, which is connected with the Takt-i-Shat at its northern extremity, but runs in the opposite direction, from west to east, being at its western end united to the Pushtun mountains. Its eastern extremity does not reach the Hindoo-coocheh, as it is separated from this great mass by a low depression, through which the drainage of the northern districts is carried by the river Ghorhound to the Kabul river. These northern districts go by the name of Koh-i-Daman. On the west they are surrounded by the Pushtun mountains, which rise in fine ridges and ranges and their offsets. The Koh-i-Daman has a length of thirty miles and a medium width of seven. The western side of this plain is much higher than the eastern, along which the drainages and valleys extend. There are in the surrounding it are spread by numerous ravines, through which rills of the purest water fall. The slopes enclosing these ravines are thickly planted with the mulberry, and every moderately level spot is planted with fruit-trees or the vine. The southern part of the plain is a stony and comparatively barren tract, the principal produce of which is fruit, for which both the soil and climate are well suited; the northern and larger portion yields grain, cotton, tobacco, artificial grasses, and various other crops, rarely any fruits are grown by which there are many inhabitants. Here, as in the valley of Peshabhr, which opens into this plain, the mulberries, when dried and ground, produce a flour, which is used in making bread.

Koh-i-Daman is a favourite country residence of the wealthy inhabitants of Kabul, and is almost as thickly studded with castles as with gardens. They are strongly built, and may be compared with the old baronial residences in England.

South of the Koh-i-Daman is the Plain of Logour, so called from the river which traverses its southern portion before it joins the Kabul river. It extends about 20 miles from west to east, and half as much in the opposite direction. In the middle there is a ridge of higher grounds, which divides the Lagour river into two branches. The level that it appears to have been formerly a lake, and at present a large portion of it is a swamp during nearly the whole year, especially along both banks of the Logour river. This is the case along the west, or the Baranak part of Kabul, and the cultivated grounds occupy only a small portion of the surface; but it is very rich in grass, an important object for a nation which keeps so many horses as the Afghans. It contains also extensive orchards and vineyards.

The basin of the river Kabul constitutes the principal article of trade. They go to Hindustan. Grapes of a dozen different kinds are grown, but only two species bear ripening. There are six varieties of apricots; of the mulberry, 20 kinds; of peaches, 7 kinds; of apples, pears, peaches, walnuts, almonds, quinces, cherries, and plums, red and white melons are raised in abundance. The wild fisher root is used to make preserves. The vegetables are excellent, but not plentiful. They have cabbage, lettuce, potatoes, beans, peas, cucumbers, roots, turnips, leeks, celery, and cauliflower: these are generally cultivated in the fields, the gardens being reserved for fruits and flowers. Irrigation is common wherever water is found.

The plain from the foot of the heights to the river, and even the most eastern part of the basin of Kabul is 6000 feet above it; whilst the western rises, in the Mydan valley, to 7747 feet. It has therefore such a colder climate than can be expected from its geographical position. It is warmer in summer than England, but in winter it is much colder. But even in summer the heat is so moderate as never to be disagreeable in the shade, and no night is so warm that a thick covering can be dispensed with. The winters however are very cold. In that of 1839-40 the thermometer was often 4° and 6° below zero of Fahrenheit.

The 3rd of December the first snow fell. The snow generally covers the ground for three months at least; but after the vernal equinox it disappears from the higher places. At this season of the year there are copious falls of rain, sleets, and snow. The changes in the temperature are greater than in England, even in the midst of the winter range of the thermometer in August (1839) was from 46° to 74° at four o'clock in the morning, and at three in the afternoon from 72° to 96°; in September, in the morning from 52° to 64°, and at noon from 64° to 92°. From the first half of October, in the morning from 30° to 68°, and in the afternoon from 64° to 92°. The quantity of snow which falls is very considerable, and is justly considered one of the principal reasons of the vigorous vegetation in the hot and dry season. There is a favourite proverb in Kabul: 'Let Kabul be filled with snow rather than gold.' In spring the rains are rather abundant, especially in April. In May they are rare, and when heavy do great damage to the fruits. In the following months only light showers are experienced.

Between the Basin of Kabul and that of Jellalabab is the mountain-region of the Lattabund Pass. It occupies about 30 miles in extent, and is filled by numerous oases from the southern range of mountains, which approach to the banks of the Kabul river in several detached groups, cut by a series of deep ravines and valleys. The whole is a succession of steep ascents and descents, and the ridges frequently rise 1000 or 1500 feet above their base, and are broken into crags and precipices. Both mountains and plains present no sign of vegetation, except in the immediate vicinity of the Kabul river, where some stunted trees are united with, but not a blade of grass. This tract is almost uninhabited. The few families here are wretchedly poor, and live in caves.

East of the mountain-region of Lattabund is the Basin of Jellalabab, which extends about 40 miles from west to east, and has an average width of about 10 miles. The surface is comparatively much higher than the adjacent elevation. Along the Kabul river is a tract varying between one mile and one half a mile in width, which is level, and low, fertile, and well cultivated. Fine meadows alternate with groves of fruit-trees and fields, on which the sugar-cane, rice, jowary, and maize are grown to a great extent. Villages and mud castles are very numerous. But at the back of this fertile strip the country is a stony desert, overgrown with numerous low and bare hills, which gradually rise higher and higher as they approach to the main range of the mountains, which in the vicinity of these mountains the country improves, and contains numerous villages surrounded by orchards, and between the villages a considerable portion of the surface is under cultivation. The soil of the middle tract is very stony or sandy. Towards the eastern extremity it is a barren, stony desert, surrounded with low hills, where, in the months of April and May, a pestilential wind or simoom prevails, which sometimes proves fatal to the traveller.

The mountain-region of Kyber sends its offsets to the banks of the Kabul river, east of the Basin of Jellalabab. It occupies 20 miles along the river, which is about 20 miles distant from this main tract. This tract also is covered with numerous ridges, which grow lower as they approach the river. Narrow passes, with perpendicular rock walls, line them: one of them is the famous Kyber Pass, whose summit is 3373 feet above the sea, nearly 1400 feet above Jellalabab, and 2300 feet above Peshawur. It is from 18 to 20 miles long in a straight line, and about 30 miles by the road. The hills are mostly covered with shrubbery, which is quite thick, and only covered with bushes; but towards the main ridge there are several smaller table-lands which are tolerably level, and being partly irrigated, yield tolerably good crops of grain. There are also extensive orchards, and groves of peach, mulberry and wild cherry.

The Plain of Peshawur extends from west to east about 60 miles, with a width varying from 30 to 40 miles. The surface is not level, but presents only long and gentle slopes, in some places broken by ravines. The greater part of it has a clayey or loamy soil, which in some places is of great
depth. It requires much watering and much stirring, but when properly treated it bears very heavy crops. The soil of those tracts which lie in the immediate vicinity of the river, and that of the island of the Deodorees, contains a considerable quantity of alluvial earth mixed up with clay, but it is inferior in fertility to most other parts of the plain. Towards the mountains, which surround it on the south like a semicircle, the country is stony, and in some parts also sandy, and of indifferent fertility. The orchards that are scattered over the surface of the plains consist of pomegranate trees, and the greater part of the plain is in the highest state of cultivation, being irrigated by many water-courses and artificial canals. Thirty-two villages have been counted, and one-fourth of four miles square. The inhabitants are wealthy and industrious. The principal cultivated grains are rice, maize, wheat, and barley. During the summer the heat is very great, and at the solstices almost insupportable. It moderates however in the month of July, when showers of rain fall or the air is cooled by winds from the east, in which quarter the rains have commenced. Sometimes a fall of snow occurs, but it melts instantly. Frost however is very frequently experienced in every season. The rains which are carried to Hindustan by the south-west monsoon reach Peshawur, but they do not last more than about four weeks in July, nor are they abundant: in some seasons they fail entirely. But the winter rains are plentiful, and more so in the second than in the first half of winter. The spring is generally abundant, but they are heavier at that time than in any part of Hindustan, Cashmere excepted. This large plain is more than 5000 feet lower than that of Kabul, the town of Peshawur being only 4000 feet above sea.

The plain of Peshawur does not extend to the Indus. From both the southern and northern mountains a ridge runs out which skirts the river at a distance of a few miles; between them the Kabul river flows in a narrow gorge, which is not traversed by a road. But at no great distance from its banks on the south is a depression in the ridge, which forms a defile, called Geder Gulna (or the Jackal's Pass), which is about two miles long, and leads to the bridge over the Indus opposite.

III. The Suliman Range and Eastern Declivity of the Table-land.—What are called the Suliman Mountains is nothing but the elevated crest of the eastern declivity of the table-land itself. The level of the Indus is seldom more than 500 feet above the sea-level, but the level of the crest of the table-land varies from 5000 to 7000 feet. When seen from the banks it appears like a very elevated mountain-range, though it hardly rises a few hundred feet above the general level of that portion of the table-land which is contiguous to it on the west.

The Suliman Mountains are closely connected with the snow-capped mass of the Sufaid-Koh, which must be considered as its most elevated summit. They extend thence southward and westward, with the vicissitude of waters and valleys which they reach 30° N. lat., where they may be said to terminate, nearly due west of the confluence of the Indus with the Gara. A little north of 30° N. lat. the crest of the table-land turns suddenly to the west, and continues in that direction between 70° and 68° E. long., where it meets the Hala mountains of Beloochistan. That portion of the crest which lies from east to west, is called the Muras and Boogtey mountains. There are very few summits which rise above the general level of the Suliman range, but these that do attain the snow-line. The most elevated has given its name to the whole range. It is the Takt-i-Suliman, which lies near 31° 30' N. lat., and rises, according to Liet L. Wood, to nearly 18000 feet above the sea; it appears as the addition of the peak which lies north of the Takt-i-Suliman constitutes a continuous chain, with the exception of one break, not far north of the Takt-i-Suliman, through which the Gomul river, which rises far in the interior of the table-land, descends to the Indus.

The descent between the Suliman mountains and the Indus river is occupied by the declivity of the table-land. The river however does not run parallel with the range; at the northern extremity the distance between them exceeds 100 miles, but it is little farther south. South of 32° N. lat. it falls short of 50 miles.

One of the most remarkable features of the northern portion of the declivity is the Salt Range, which is broken by the Indus river near 39° N. lat., nearly at a right angle, and extends from its western bank west-north-west 'o the Suliman mountains, which it reaches a few miles south of the Sufaid-Koh. It is composed of sandstone, containing very thick and extensive layers of rock-salt, which are largely worked near the town of Kalalagh, just on the banks of the Indus, whence it is exported to different parts of Hindustan and other countries. The Salt Range does not rise more than 2000 feet above the banks of the Indus; but it is probably higher farther to the west. The rivulets and springs are brackish, and the land very poor. A few flocks of sheep and goats are kept. The cultivated land is scattered in small patches. It requires permanent irrigation, and a continuation of favourable weather to raise the coarsest kind of grain.

Between the Salt range and Kyber mountain lies a table-land called the Indian table-land, whose elevation varies from 700 to 900 feet above the level of the Indus; for this is the elevation of the precipitous rocks which here form its western banks. The surface of this table-land is traversed by several ridges, rising from 500 to 1000 feet above their base; they are covered with soil, but of indifferent fertility. The depressions however between them, especially those near the river Toe, have great productive powers, as the soil rests on limestone. They are almost entirely covered with well-cultivated fields, carefully enclosed and abundantly irrigated by the waters of the Toe or other perennial streams, which receive their supply from the Sufaid Koh or its neighbourhood.

The country south of the Salt Range is drained by the river Koornam, which also rises in some of the southern offices of the Indus. The Koornam however falls into a considerable number of small rivers, which descend gradually to the Indus, until it terminates in a plain of considerable extent called Bunnoo. The higher part of the valley bears the name of Bungah-i-Bala, or Upper Bunnoo; the lower is called theratings of the river are low. The plains are much cultivated, and possesses a considerable degree of fertility, especially where the crops do not depend on the rain, but on irrigation from the river or its affluents. The whole, but especially Bunnoo, is well cultivated and populous. The principal crops are barley, rice, and wheat, along the coast, and along the banks which enclose this region, no domestic animals are kept but those which are used in cultivation, cattle and buffaloes.

That part of the declivity of the Suliman mountains which lies south of the Koornam river goes by the name of Damam. Here the nature of the country changed. It is not descended by an inclined plain, but by terraces, each of which is enclosed by two ridges running south and north. In some places there are three, in others four such terraces. Some of the ridges are perpendicular; in general they only have stone shores, with shrubs and bushes, and contain pasture-ground. Some of the valleys between the ridges are sandy, and can only be used as pasture for camels, goats, and sheep; but the larger number of them have a good clayey soil, intermixed with sand, and are planted with the chief crops of the Indus; their fertility is considerable. Wheat, barley, and several of the grains of Hindustan, as jowary, bajra, &c., are cultivated to a great extent. Considerable quantities of cotton, hemp, and silk are exported. It is little excepted dates. Cattle are the chief stock, but sheep are also numerous, both of the heavy-tailed and light-tailed species. Each of the valleys is inhabited by a different tribe; sometimes two tribes live in one valley. Their villages are numerous and often very large. They are enclosed by the walls of the river, which descend to the water from 2000 to 4000 houses, with bazars and numerous shops, in which most of the Indian goods are sold by the Hindu families settled in these places.

Our knowledge of the country that portion of the declivity which lies south of the Gomul river is incomplete. It appears that here also it consists of terraces rising one above the other, and that there are valleys between the ridges; but we know nothing of these valleys and their inhabitants. The cultivation of the plains and the banks of the Indus is separated from them by a rather hard tract from 15 to 20 miles wide. The soil consists of a stiff and hard clay of an ashy colour, which is very difficult to be cultivated. Towards the river however it is much softer, and this part has been washed by the waters and has improved its quality. Near the base of the mountains the soil is partly covered with stones or sand, or both, which have been washed down by the rains. At the southern extremity of this region, north of Mitrun-koh, is a very desert of some extent called Dajul; the hardiness of the clay
develops the greater part of this tract from being cultivated. It is chiefly a jungle, but there are other tracts which are without jungle, and these may be even more valuable. In the depressions, moderate crops of jowary, bajra, &c., are raised, if the rains have been abundant. Along the Indus and smaller watercourses the country is well cultivated, and it is the nature of the soil that between the desert valley and the jowary are the chief crops. The principal domestic animals are camels; but cattle, sheep, and asses are also kept in most places. The villages are small and distant from one another, containing moderate elevations, and the steep, rocky cliffs and places many isolated hills occur, which are only separated from each other by ravines. The valleys however in this tract have a very good soil, and are well cultivated. South of Ghuznee the surface is less broken. The hills are at great distances from one another, and the pasture on the slopes or 20 miles long and wide, and it is only in a few places that their surface is broken by low hills or deep ravines and watercourses. The soil here and farther north is a loam with a great proportion of clay; but stones, gravel, and sand have been lodged by the rain under the hills. As the quantity of rain which falls on this region is small, the lands require irrigation in order to be productive, but the rivers are small and cannot yield a large supply. To obtain this supply the inhabitants have constructed a kind of aqueducts, by which the water of a hill or rising ground is brought out at its foot in a rivulet, to be disposed of at the pleasure of the farmer. Such aqueducts, called kareezes, are made in the following manner. A bed of earth where it is necessary is broken up to a depth of 6 feet, and above it in the acclivity is dug another at the distance of five to twenty yards, according to circumstances. The wells are continued at distances generally equal, until the quantity of water collected in them is deemed sufficient, or until the depression becomes too deep, so that the expense exceeds the advantage. If the acclivity is not very gentle, the highest wells must be very deep, as their bottom must be only slightly elevated above the level of the water in the lower wells. All these wells are means of aqueducts made under the surface of the ground, through which the water from all of them flows to the foot of the hill. Very good kareezes will turn a small mill of the country. This ingenious contrivance of irrigating the fields is the means of the fertility of the country, as in the neighbourhood of Ghuznee a kareez of great extent is found which is ascribed to Sultan Mahmood. Including its branches it is asserted to be nearly 30 miles long, but this is probably an overstatement. More however are two or three miles long. These kareezes are found in other parts of Afghanistan and in some parts of Persia and Turkistan, but nowhere are they so numerous as in this part of the table-land, which thus produces rich crops of wheat and barley. The grain is consumed by the inhabitants, and the fruit is inferior to that of the valley of Kabul. There are numerous villages, and they are tolerably large. They are enclosed by mud walls, as these districts are surrounded on all sides by mountains, which render it necessary for editorial and commercially significant excursions into the lands of their neighbours. South of the fortifications, which are called Kelat-i-Ghilzire, the aspect of the country changes. The surface is much more broken; flats are rare and of small extent; hills and even short ridges are common. Water is scarce, and only to be found at greater depths below the surface. The soil chiefly consists of sand, which in a few places is intermixed with clay, and moreover it is covered with stones, which in some parts are so numerous as to prevent the growth of grass from springing up. This is especially the case with those tracts which lie at the foot of the Kohoj Amran range, where a large space appears like a sea of rocks and stones. In this country cultivation is limited to the banks of the larger rivers, where some level tracts of moderate extent are found, and where a small river of fresh water can be turned to account for irrigation by damming up its bed. Nearly the whole of this country is pasture-ground, in possession of the tribes, and some of these are very considerable. Only a small tract where cultivation is carried on to a great extent. This lies in the vicinity of the town of Kandahar, on both sides of the river Urgundab, from whose banks it extends at some places seven miles inland. Wheat, rice, etc., are grown. The country is rich in orchards, which contain vines of various kinds, apples, pears, quinces, nectarines, peaches, figs, plums, apricots, and cherries. The pomegranates of this place are held in great esteem. Except these plantations, the whole of this region is without

There occur some ridges of considerable extent, which rise from 1000 to 2000 feet in elevation. The most extensive are the Djarah-Koh, north of 33° N. lat., which is parallel to the Sir-i-Koh mountains and is not much lower than that range, and the Gante-hills, cast of Kandahar, which extend east and west. The most northern district, which lies west of the range, is the most uneven. It presents hardly a level tract of any extent, but is in general broken by ravines and watercourses, most of which exhibit numerous ascents and descents of different degrees of steepness. The surface in many places is only separated from each other by ravines. The valleys however in this tract have a very good soil, and are well cultivated. South of Ghuznee the surface is less broken. The hills are at great distances from one another, and the pasture on the slopes or 20 miles long and wide, and it is only in a few places that their surface is broken by low hills or deep ravines and watercourses. The soil here and farther north is a loam with a great proportion of clay; but stones, gravel, and sand have been lodged by the rain under the hills. As the quantity of rain which falls on this region is small, the lands require irrigation in order to be productive, but the rivers are small and cannot yield a large supply. To obtain this supply the inhabitants have constructed a kind of aqueducts, by which the water of a hill or rising ground is brought out at its foot in a rivulet, to be disposed of at the pleasure of the farmer. Such aqueducts, called kareezes, are made in the following manner. A bed of earth where it is necessary is broken up to a depth of 6 feet, and above it in the acclivity is dug another at the distance of five to twenty yards, according to circumstances. The wells are continued at distances generally equal, until the quantity of water collected in them is deemed sufficient, or until the depression becomes too deep, so that the expense exceeds the advantage. If the acclivity is not very gentle, the highest wells must be very deep, as their bottom must be only slightly elevated above the level of the water in the lower wells. All these wells are means of aqueducts made under the surface of the ground, through which the water from all of them flows to the foot of the hill. Very good kareezes will turn a small mill of the country. This ingenious contrivance of irrigating the fields is the means of the fertility of the country, as in the neighbourhood of Ghuznee a kareez of great extent is found which is ascribed to Sultan Mahmood. Including its branches it is asserted to be nearly 30 miles long, but this is probably an overstatement. More however are two or three miles long. These kareezes are found in other parts of Afghanistan and in some parts of Persia and Turkistan, but nowhere are they so numerous as in this part of the table-land, which thus produces rich crops of wheat and barley. The grain is consumed by the inhabitants, and the fruit is inferior to that of the valley of Kabul. There are numerous villages, and they are tolerably large. They are enclosed by mud walls, as these districts are surrounded on all sides by mountains, which render it necessary for editorial and commercially significant excursions into the lands of their neighbours. South of the fortifications, which are called Kelat-i-Ghilzire, the aspect of the country changes. The surface is much more broken; flats are rare and of small extent; hills and even short ridges are common. Water is scarce, and only to be found at greater depths below the surface. The soil chiefly consists of sand, which in a few places is intermixed with clay, and moreover it is covered with stones, which in some parts are so numerous as to prevent the growth of grass from springing up. This is especially the case with those tracts which lie at the foot of the Kohoj Amran range, where a large space appears like a sea of rocks and stones. In this country cultivation is limited to the banks of the larger rivers, where some level tracts of moderate extent are found, and where a small river of fresh water can be turned to account for irrigation by damming up its bed. Nearly the whole of this country is pasture-ground, in possession of the tribes, and some of these are very considerable. Only a small tract where cultivation is carried on to a great extent. This lies in the vicinity of the town of Kandahar, on both sides of the river Urgundab, from whose banks it extends at some places seven miles inland. Wheat, rice, etc., are grown. The country is rich in orchards, which contain vines of various kinds, apples, pears, quinces, nectarines, peaches, figs, plums, apricots, and cherries. The pomegranates of this place are held in great esteem. Except these plantations, the whole of this region is without
trees. Poplars and willows are planted along the watercourses. Gladiolus and reeds, when the water is low, crowd the naked plate of the table-land, is very cold. The winter lasts four or five months. The snows are extensive and sudden, but little snow falls. Whilst the British army was there (1840) the ice in the pools of water and the ditches of the fort was several feet thick, though the winter was considered mild. Temperature increases daily between sunrise and three o'clock in the afternoon varies from 40° and even 50°. From the 26th of April to the 26th of June the thermometer ranged from 50° to 72° at four and five o'clock in the morning, and from 85° to 110° at three o'clock in the afternoon. In April the thermometer was 72°, in May it was 79°. Between the middle of May and the end of August two hot periods each of forty days occur; the second period is hotter than the first. In summer rain is very rare and only falls in short showers. The greatest quantity of rain falls before the vernal equinox, but only in showers.

VI. The Southern Table-land. Lies between the Kohgal Aurnum range and the Murree and Boogtee mountains, and descends to the west, where it terminates in the Desert of Bellochistan before it reaches 6000 feet elevation. It consists of the valley of the river Lorah and the country of Shawl. The Lorah rises on the borders of the Eastern Table-land, and as it runs eastwards drains the valley of Pseeben, and then enters the country of Bellochistan, where it terminates in a lake, which in spring is of considerable extent, but nearly dry at the end of the summer. The elevation of this region above the sea along the road leading from the Dolan Pass to the Kohjak Pass, which traverses it nearly in its middle, is from 9000 to 9200 feet. Near the north end of the country is a rather level, but interspersed with numerous low hills; along the banks of the river only few hills occur, but they are numerous near the Murree and Boogtee mountains. The greater part of the lower country is not cultivated, and overgrown with wild thyme or a jungle of tamarisk. Some tracts are cultivated with wheat, but they are not extensive, as the water for irrigation is derived from karezees, the bed of the river being from 200 to 300 feet depressed below the ground at some spots. Near the north end of the country the river descends, and passes between the lower country to the west and the hills of the table-land of the west, and here is the cultivation of which is applied to the plain through which the Helmand runs, on the banks of which there are many small irrigation canals; the other plate cultivation is limited: cotton is cultivated to some extent. This region appears to be divided between agriculturists and nomadic tribes. The climate is not so cold as that of the northern and eastern part of the central plain, and probably as temperate as that of the hills of the Khyber, which lies at a higher elevation, and where the air is almost as high as that of the Kohak-valley. A large portion of this region is covered with snow in winter, but in spring the snow in the mountain-regions of the north fills the wide bed of the rivers, and in the higher grounds however the snow is burnt up after the summer solstice, and then that part of the rivers is swelled with their herds to the mountains of the Hazarak and Eimack, especially to the elevated plain on which the Helmand rises.

IX. The Table-land of Herat comprehends that part of Afghanistan which lies west of the mountain-region of the Eimack, and extends westward to the boundary-line of Persia. The mountains of the Pajaranibus lower gradually until they constitute low ridges of rocky hills, which run in various directions, but generally north-eastern, and south-southern. They are mostly bare, except for a few months in the year, when they supply pasture-ground for sheep and goats. Between these ridges there are level tracts. Some of them are sandy and sterile, and nearly unirrigated, but others have a soil in which the sand is mixed with a great proportion of clay or loam, and are very fertile—such are the plains of Subzawar and Herat. The first is 30 miles long and 20 wide, and partly cultivated. The plain of Herat is about 30 miles long and 18 wide. It is watered by the Helir-rood, a river which rises far to the east in the mountains of the Hazarak, and all the year round brings a considerable volume of water to the plain, over which it is spread by numerous canals. A bund or dam is thrown across the river, and the water is turned into the canals, and conducted over the whole plain, which is covered with fortified villages, vineyards, orchards, gardens, and corn-fields. The heat is excessive for two months in summer, but the winter and spring are agreeably cool.

Climate.—The degree of heat and cold experienced in Afghanistan differs greatly in different places, in proportion to the elevation of the different parts of the table-land. The heat is insupportable in Seistan, especially in the Gurmahar and the Helamb, which is so hot that the maximum is about 120° and even 130°, but in Guznem and Kabool it is very moderate. The rains which accompany the south-west monsoon extend to the eastern border of the table-land, but at this distance from the sea they are scanty, and last only about
a month, from the middle of July to the middle of August. In the valley of the Kabul river they never extend beyond Jalilabad, where only a few showers fall; but they are much more abundant in Bumnoo and Bungah-i-Bala, and in the north and other countries beyond the Indus. These rains do not appear to be experienced on the table-land itself. The winter rains, accompanied with falls of snow, and the spring rains with sleet, are abundant in the valley of the Kabul river and the central table-land; but not so much in other parts of the country where the climate is not so moist, which is the reason why it is unfit for agricultural purposes. The summer is dry, and generally no rains fall to the higher regions from May to September or October.

**Productions.**—Afghanistan has great mineral wealth. Gold is found in several streams which originate in the Himalaya mountains or in the Hindoo-cooeh and fall into the Indus or Kabul river, and it is collected in some places. Silver is said to exist in the Hazara mountains. Copper ore is abundant in the hills which extend west of the Sasafid-Koh to the neighbourhood of the town of Kabool, and at some places it is so rich as to yield from 60 to 80 per cent. of metal; but it is not much worked. Iron is found in the greatest abundance in the Himalaya mountains north of the Plain of Peshawur, and of the best quality. It is extensively worked in a district called Bajour, where it goes to Cashmere, the Panjash, and to the other parts of Afghanistan; in Kandahar it is used for the firearms of the Kirghises. Silver and copper are equal to the best Swedish iron. Other iron-mines of great extent are on the eastern table-land, at Foornool, in the country of the Wuzoorees, not far from Kangourum; there are two kinds of iron here; one is converted into steel. Iron-mines are also worked in the mountains of the Hazara. Lead of excellent quality is worked in the Hazara mountains, and also in the Pughman range. In the last-mentioned mountains plumago is found, and sulphur in the Hazara districts. Salt is obtained in the greatest abundance from the Salt range. Lignite has been discovered in the country of the Wuzoorees, not far from the iron-mines of Foornool; on the mountains east of the central range there are salt-mines of ancient date; salt is still obtained in some parts at the Hazara mountains. Saltpetre is obtained in considerable quantities from some pits in the vicinity of Peshawur. Near Kalsabagh on the Indus great quantities of coal are got.

The grains cultivated are wheat, barley, peas, beans, maize, rice, and some other grains of Hindustan, as jowary, chana, musoor, bajas, moth, moong, oord, and muthwa; and two crops are annually obtained in the valley of Kabul as far as Mullad; the winter crop consists of paddy, rice, carrots, turnips, radishes, lettuce, cress, cauliflowers, onions, garlic, melons, and cucumbers, with a few others from Hindustan. The fruit-trees have been mentioned in noticing the valley of the Kabul river. No natural grass is cut for hay, except in the provinces of Kandahar and Mullad; but the trees are grown, but they are different from ours. Barley is cut when green near Peshawur twice or thrice, with little injury to the crop; but wheat is more delicate in this respect, and can only be mown once. Mullad is extensively grown on the central table-land, and in Zemini Dawk, and goes from Kandahar to Shikarpour. Turmeric is cultivated in Bumnoo, and also exported to Sind. Assafetida grows in many parts which are very elevated; the greatest part of the produce is taken to the coast, for it is used in the manufacture of soap, or for medicinal purposes. Various kinds of spices are found in this country, and the leather is indifferent. Several wild shrubs furnish food from their roots, bark, flower, or fruit. The fruits of some kinds of berries and of the wild vine are much used.

Forests are only found on the Himalaya mountains and the Sasafid-Koh. There are no woods on the table-land, and all the trees found there are planted, generally in rows along the water-courses and canals, and around the orchards. Only willows, poplars, and other trees are found in the plains of their Irang, but the leather is indifferent. Several wild shrubs furnish food from their roots, bark, flower, or fruit. The fruits of some kinds of berries and of the wild vine are much used. The productions are one-third of this, it is calculated to support a far greater population than tillage. The produce is little affected by the seasons, and is very regular. Silk is not produced to any great amount, except in a few places. Nearly all the fruits cultivated in Afghanistan are also found in a wild state, chiefly in the valleys of the cool mountains, such as apples, pears, cherries, plums, apricots, peaches, quinces, and pomegranates.

The most important of the domestic animals are the sheep. There are two kinds, both with the broad fat tail, which in some parts of the country are kept for the saddle, and in other parts the cart is put under the tail. Herodotus (i. 113) says the same of the sheep of the Arabs. They constitute almost all the wealth of the mountain-region of the Hazara and Eainack, and the inhabitants are dependent on the wool to supply their wants, and for the clothing of their camels and ghees. These sheep yield two fleeces: the spring or coarser fleece is used for carpets, grain-bags, and other coarse stuffs; the autumn or finer fleece is manufactured into cloth, cloak, and mummadis or rugs. The numerous flocks which pasture on the table-land yield only once or twice a year. These fleeces are nearly as numerous as sheep. Those in the Koh-i-Dela mountains and the Paropamisus yield, like those of Cashmere and Tibet, a fine and remarkably soft down, which grows on the root of the hair. The hair is long and usually jet black, but the down is of a shade more or less intensive. The down is in great demand, and exported to Persia, Kabool, Kandahar, Herat, and Shikarpour, where it is employed in different manufactures.

Horses are plentiful, but of an inferior breed, except in Bumnoo and Danan, where there is a good breed. In some places there are good ponies; mules and asses are numerous, and in many places they are the principal animals of burden. A great many camels are found in this country; they are also the principal beasts of burden in the whole of Hindoo-cooeh to the borders of the desert. The quality of these camels is generally much greater than those of Hindoostan. It is also found in the Bactrian camel with two humps. The number of cattle is small, as the pastoral tribes keep only a few bullocks to carry their tents, and a few cows which are fed near their residences. In the vicinity of Lake Hamoon great herds of cattle are pastured on the marshy grounds. In Afghanistan they are of an inferior breed. Buffaloes are kept at some places, but they are not numerous. The cats of Kabool are distinguished by their very silky hair. The number of sheep is great, but though very few of them are found in Persia, and none are exported from that country. These cats are exported in great numbers from Kabool, where the people encourage the growth of the hair by washing it with soap and combing it.

Llamas and tigers are said to exist, but they are comparatively weak and timid. Leopards are found in the Hindoo-cooeh. Wolves, hyenas, jackals, foxes, and hares are common everywhere. The wild hog is not frequently met with, but it is abundant in the province of Peshawur. Many kinds of deer, and also the elk, are found in the mountains, and a few antelopes in the plains. Wild sheep and wild goats are common in some parts of the mountainous countries. There are also porcupines, hedgeshogs, ferrets, and wild dogs. Monkeys occur only in the mountains near the Indus.

The common fowl is kept by the pastoral tribes; in some places it is wild. Water-fowl are abundant on Lake Hamoon. Domestic fowls are rare everywhere. Fish is very scarce. Locusts are most frequent in the eastern countries, but even there they rarely lay waste any part of the country.

**Population and Inhabitants.**—The population is estimated at 14,000,000, inclusive of Beloochistan, but many persons think it is greatly exaggerated. A large proportion of the ruling nation are dispersed over the whole of the table-land; but the mountains are mostly in possession of other tribes, such as the Hazara and Eainack in the Paropamisus. Among the Afghans, the Tajiks, Turcomans, Pathans, Zemindaris, Arabs, with a few of the Armenians, Assyrians, and Calmucks.

An account of the Afghans has been given in F.C., vol. i. p. 169. The Hazara and Eainack, or the inhabitants of the Paropamisus, do not appear to the stranger as being a people of great energy; the chief occupation of the inhabitant of Afghanistan derive their origin, as their physical appearance shows. They are evidently of Mongol race, though at present they speak a dialect of the Persian language, and are the subjects of Sultan Abak the first Mogol. It is said that they are a colony of Mongols left in this country by one of the armies of Manka Khan, one of the successors of Genghis Khan. There is some difference in the manner of life of these two tribes. The Hazara, who occupy the higher part of the Paropamisus, have fixed abodes. They live in small villages consisting of low huts. Vol. I.—H
where they pass the winter season under one roof with their cows and sheep, using as fuel small dry shrubs and the dung of their cattle. In summer they live with their animals on the slopes of the mountains. Near their villages they cultivate small fields, which they live in and which elevation is not too high, wheat. The Emirnck lead a more nomadic life, and reside the whole year round in tents made of dry sticks or felt, and go with their flocks in summer to the higher elevations in winter to the lower elevations of their mountainous districts, where they make a tributary of their tents throughout the year. Each tribe is divided into many divisions, each of which is independent of its nearest neighbour: and they have frequent feuds with one another, in which many young persons are taken prisoners and sold as slaves in Turkistan. They are visited by traders from Herat, Kandahar, and Kabul, who furnish them with some common articles of dress and utensils, and receive in return slaves, cattle, clarified butter, woollen cloth, grain sacks and carpet bags, felts for horse-riding, and carpets, all made from the produce of their flocks. They also furnish lead and sulphur.

That portion of the population on the table-land which is occupied with agricultural pursuits is known by the name of Tadjiks or Tadjikis. They are found in all the countries of Western Afghanistan; from the Mediterranean to Chinese Turkistan; and even in the last-mentioned country many families of Tadjikis are settled. In a few mountainous countries they have maintained their independence, in all others they are subject to the prevailing powers; have conserved their language, and have preserved their pastoral habits. Their condition may be compared to that of the serfs of the middle ages in Europe. They are the glebe adscripti, who work the cultivated grounds, and are obliged to give up to their masters one-fourth or one-half of their produce. They are peaceful, industrious, peasants, more civilized, intelligent, and skilful than their masters. In the towns they constitute the labouring classes; they are tradesmen, mechanics, and labourers. They generalize were made and follow the custom and tradition of their tribe. They have preserved their language, which is however mixed with many terms derived from the language of the predominant nation. Their language is learned by all the Afghans who wish to be considered as men of education.

In the Plain of Peshawar and the neighbouring districts many Hindkies, as they are called, are settled as agriculturists. Their language is a kind of Hindustanee, resembling the dialect of the Panjab. The number of Hindus settled in Afghanistan is very great; there is not a single village in any country except a family or two, and in the larger places there are many. They keep shops; are brokers, merchants, bankers, goldsmiths, sellers of grain, and other occupations. They retain the Hindu features, and some of them have adopted the dress of the Hindus; the great men of the country in every kind of business connected with money or accounts.

The Kuzilbashies are only found in towns, except about Herat, where they are also settled in villages. A great number of them are in Kabul, where they were settled by Shah Nadir and Ahmed Khan. They are Türkmen, and their ancestors were members of some of the tribes which wander about in the plains of Persia. They are mostly soldiers, or employed by men of rank as secretaries, masters of the household, and stewards. Some of them have acquired landed property, which they let out to Afghans or Türk tenants. They are lively, ingenious, elegant, and refined, but fond of luxury and requisites.

Arabs are settled in Kabul and Jellalahad. They are agriculturists, and do not mix much with the other inhabitants; they have lost their original language. According to Elphinston, the number of their families amounts to about 2000. And there are still many in different parts of the country. Arabs are imported into Afghanistan, as well as into Hindustan, as slaves, and generally form a part of the king's guards. There are also Calkisks in the king's guards; but some tribes of that nation are settled near Herat as agriculturists.

The population is very unequally distributed over the country. The most populous parts are the valley of the Kabul river, the country south of the Sooludd-Roh and of the Salt range, the central table-land north of Kolti-Gijes, and the immediate neighbourhood of the towns of Kandahar and of Herat. All the other parts of the population is scanty, as the inhabitants lead chiefly a nomadic life, with the exception of the fertile tract round Lake Hancow, where there is a considerable agricultural population.

The capital of the whole bulk of the Afghanistan is given by Wilken in the 'Transactions of the Scientifie Society of Berlin, 1818-19, in which he compares the constitution of the tribes of the ancient Persians, as exhibited by Herodotus and Xenophon, with those of the modern Afghans, and point out the great difference between them, which he attributes in a curious manner as a result of the events and transactions of the time of the first Cyrus.

Manufactures.—Manufactures which supply articles of export are few and comparatively small quantities, it appears that the manufactures of the country are sufficient for the home consumption, as no manufactured articles are imported from India except cotton stuffs. As a knowledge of the manufacturing arts conveys an idea of a nation's civilization and of the comfort which it enjoys, we transcribe from Elphinston's work the following list of the trades exercised in the town of Kandahar:—Jewellers, gold and silver smiths, book-sellers, book-binders, stationers, makers of kulfumanda (a sort of incense) and copies of the Koran, doorkeepers, gunsmiths, seal engravers, sellers of armour, sellers of shields (the shields are of buffalo or rhinoceros's hide), puszum, sword-cutters, polished and steel, sellers of bows and arrows.

They also make black or white felt, and work in silver, pewter, brass, glass, tin, copper, silver, graving-bags, black, bags, rags, felt, felt cloaks, mittens, soaks, and horse-cloths. The felt cloaks are called koonas, and are extensively used in Kandahar, where they are much prized.

Commerce.—As Afghanistan has no navigable rivers, the transport of merchandise is expensive, and the commerce which is increased by the want of roads, which are not met with in all Western Asia from the Indus to the Straits of Constantinople. The conveyance of merchandise is therefore effected by means of beasts of burden, and the conveyance of goods from one country to another is in great measure done by foot. The most northern of these lines begins on the frontiers of the British Possessions at Ladiana on the Sutlege, passes through Lahore, and reaches the Indus at Attock. Hence it runs through Peshawur to Kabul, where it divides into two roads. One road runs over one of the elevated mountainous districts of the Indus-valley crossing the Russian and the Russian mountain and descending to the plains of Turan, leading to Kandahar and Khulam, and thence to Bokhara. The other road runs from Kabul south-south-west to Kandahar, at which place all these lines converge.

The middle line of commercial communication passes from Lahore direct west, crosses the Indus at Dera Ismail Khan and ascends the Gomil Pass, which is also called the Golgar Pass, and which leads across the eastern table-land. When it reaches the sea coast of the Caspian Sea, it divides into two branches, one of which runs northward to Guizande and Kabul, and the other to the south-west to Kandahar.

The third road connects the Indian Ocean with the Caspian. It begins at the seacoast of the Caspian Sea, and runs chiefly along the banks of the river of Shikarpore, whence it diverges to the north-west, and passing through Darud in Cutch Gavinda, ascends the table-land by the Pass of Bokh. From this place it continues through Quettah over the Kigal Pass to Kandahar.
Russia are also imported by these caravans, especially raw cotton, cottonseed, and other raw materials, needles, looking-glasses, Russia leather, tin beads, and spectacles. A fine cloth made of camel's wool, some raw cotton, and some lamb's wool are also brought from the town.

**Tourm—** A description of the towns of Kabool, Peshawar, Ghuznee, and Kandahar has been given under Afghanistan, F. C., and that of Furfur is noticed under Shiraz, the inhabitants are very poor, and the look of their town is very insignificant. Imports from the Persian market consists of coarse cotton-cloth, muslin and other fine manufacture, some sorts of silk cloth and brocade, indigo, ivory, hemp, wax, tin, sandal-wood, and a large quantity of sugar, musk, coral, and some other trifling articles.

The traffic carried on by the Gonul Pass and Dera Ismael Khan appears to be more important. It is entirely in the hands of the Lehan merchants, a tribe which pretends to be of Afghan origin. They arrive annually with three kafislas at Kandahar and Kabool. The first kafislas leaves Dera Ismael Khan about the middle of April; its merchandise consists of coarse cotton stuffs and salt, which are sold at Kandahar and Kabool. The second kafislas brings indigo from the Ganges, who are about the middle of April, and departs from Dera Ismael Khan about the end of April; some part of these goods go to Bokhara. The third kafislas departs from Dera Ismael Khan about the middle of March, and the bulk of its cargoes consist of kinkal (or cotton), which is divided among the different bazaars and similar articles; a great portion of these goods is taken to the plains of Turan. The last kafislas only brings goods back, and arrives at Dera Ismael Khan in the middle of October with pomegranates, almonds, raisins, and chocolate from Kabool and Kandahar, and with horses, cochineal, nankin, gold thread, raw silk, and other goods from Bokhara.

The commerce between Shamkarpour on one side and Kandahar and Herat on the other, is more important. It is carried on in the same manner as that of Cabool, and consists of a much greater number of camels. The articles which they import into Afghanistan are indigo, hemp, metals of all kinds, country coarse and fine cotton-cloth, Moottanee coarse cloth, silk manufactured at Shirakpoor, and other places in Sind, groceries and spices, raw cotton, coarse sugar, opium, hemp-seeds, shield of buffaloes' and rhinoceros's hide, leather, embroidered horse-cloth, and dry grains. To these are added several articles of British manufacture, such as red and white striped cottons, with a yellow border, the best bleached, the next bleached, a coloured coarse broad-cloth. The returns from Kandahar and Herat consist of raw silk to the amount of 50,000 lacs annually for the manufactures of Sind, turquoise earth, churus (an intoxicating drug prepared from hemp-seed and opium), gum, silk stuffs of various kinds from Herat, dried fruits (such as prunes, black grapes, apricots, almonds, and dates in great quantities), tin thread for embroidery, broken copper and brass vessels (to be re-manufactured at Shishtam), meyer (an important article), especially that grown near Kandahar, saffron from Bukna, west of Kandahar, safflower from Herat, gum salop from Herat, anemone by Bella in Las (an important article), assafetida (an important article) and other drugs, a very fine description of cotton from Herat, cochineal from Herat, and other materials used as dyes.

An active commerce is carried on between Herat and Meshed and other towns in Persia. The exports from Herat consist of wool, cotton, and other goods, saffron from Kandahar, Moottane chintz, Indian brocades, muslin and other cotton-cloth, assafetida, lead (from the mines of the Eimack), cast-iron, saffron, pistachio-nuts, guns, a yellow dye, caraway seeds, and paper. The imports of Herat are chiefly silk, dates, tobacco, and a little opium.

Several caravans go annually from Kabool to Bokhara. They export chiefly articles which have been imported from India, especially shawls and shawl-cloth, white cloth of all kinds, and also cotton-cloth, and they import from Bokhara principally horses, gold and silver in coins and bars. Some articles brought from
number of tumuli is in the plain of Jellalabad, particularly on both sides of the river Surkhrud; but they are also in other places, and on the northern side of the Kabool river. Others are found in the neighbourhood of Kabool. A few small tumuli on the Koh Daman, a low and small group of mounds only, was found at Wardhe, near the river Logur, before it enters the plain of Kabool.

All the tumuli, which are in a tolerable state of preservation, consist of a low mound of earth and small stones, and a cupola, sometimes a few feet in diameter, resting on it. This construction always terminates above in the form of a cupola, which is sometimes so depressed as to exhibit merely a convexity, but it generally approaches to the form of a cone. These edifices are substantially constituted of the same materials as the tumuli which have been described before. They vary greatly in dimensions, some of them having a circumference of 144 feet, and many of only 108 feet. The front, as it appears, is directed to the east, and is surrounded by a recessed way, or a path cut in the earth. They are situated on the skirts of hills or elevations separated from each other by ravines, and in their vicinity there are always many caves, which apparently have been used as dwellings; they are supposed to have been the abodes of priests. Near them there are also always one or more tumuli, but there are tumuli where no tops are found; and in general such tumuli abound all over Afghanistan.

Most of the tops contain passages or tunnels extending from the tumuli or mound, and the centre is occasionally occupied by a small apartment. In these apartments or their recesses are found caskets or vessels of copper or stucco. These vases are sometimes of a globular and sometimes of a cylindrical form, and in many cases contain small rings of gold or silver, often of both. These vessels are often ornamented, but often also are one within the other. One of these smaller vessels generally contains a fragment or two of bone, and these appear to have been the relics over which the monuments have been raised. The whole is carefully wrapped up in an envelope of fine linen. The larger vases usually contain a portion of finely pulverized earth or of ashes; in which are found burnt pearls, beads, rings, seals, and other trinkets, with rare shells, mother-of-pearl fragments, mother-of-pearl shells, &c. In some of the deposits they have been accompanied by twists of tuss-leaves (probably the inner bark of birch), inscribed internally with characters, but they crumble away when they are handled. Some vases contain minute gold and silver cups, beads of pearls, of crystal, agate, coral, and small ornaments of gold and stone, and some coins.

The prevailing opinion respecting these extraordinary buildings is that they were created for the religious ceremony of the relics of Buddha, and that this country was once peopled by nations which had embraced Buddhism. This opinion is supported by the accounts of two Chinese pilgrims, one of whom, Fa Hien, visited the Holy Land of Hihamu, i.e. Hiham, situated about 400 miles north of the frontiers of Afghanistan, about 630 or 650. Both of them state that a hundred years after the death of Buddha, or about a thousand years before the Christian era, his adherents began to settle in this part of the Himalayas, and to build their temples or stupas, and at the time of their travels they found numerous monuments of this description along the road.

Another kind of antiquities are the coins. Single coins have been found at several places. But they occur in great numbers in the Plain of Bighram. They are situated in the Koh Daman, where the rivers which drain that valley unite and take their course to the south-east towards the Kabool river. The plain contains about 24 square miles, and, except some slight ridges, the whole surface is covered with piles of disintegrated bones and ashes; it is a flat plain, on which rain stagnates as it falls. Mr. Masson employed several years to gather the coins found in this plain, and in 1837 he succeeded in collecting 60,000 copper coins, besides a number of silver and gold coins, a large number of engraved sandal-wood, some of them inscriptions, figures of men and animals, particularly of birds, cylinders, parallelogrammatic amulets with sculptured sides, rings, and a multitude of other trinkets, generally of brass or copper. When Lieut. Wood in the following year visited the Koh Daman, he found them in search of coins, and in a few hours they returned with 35 copper pieces. It is further stated that from time out of memory coins have been collected on this plain, which have been buried and dug up, and that in some years as many as 30,000 pieces have been carried off. We are at a loss to explain in what manner or for what purpose such a number of coins have been heaped up at this place. Some think that it is the site of one of Alexander's frontier colonies, of Alexandria near Caucasus, and that it has been for a long time a very large town and the metropolis of a great empire. But in that case extensive ruins would exist, or the ground would have been covered with small and large stones, which only a few of such eminences occur, and it is far from being certain that they are the remains of buildings. But if it be admitted that the Plain of Bighram was the site of a large town, one would be surprised that the small group or mound there only exists for a comparatively short period. But the coins collected by Mr. Masson embrace a period of more than 1250 years, the oldest being coined 256 years before the birth of Christ, and the last about a thousand years after it. If the coins had been left where they were after a town of the sort had been destroyed, it would be most abundant, and those made in remoter times rare in proportion to the time which had elapsed since the destruction took place; but that is not the case: more than 2000 coins were struck during the reigns of the Bactrian kings Menander and Apollodotus, between 126 and 100 B.C.

The coins found on the Plain of Bighram are important historical documents. They throw light on the darkness in which the history of Turan and Afghanistan is involved between the time when these countries were conquered by Alexander and governed by his successors, and the introduction of the Mohommedan religion, or from about 200 before Christ to about 1000 of our era.
According to these lists, several kings reigned at the same
time, or at least several persons acted as independent sove-
igns and coined money. [BACTRIAN COINS, P. C. S.]

Besides the kings placed in Mr. Prinsep's list there is still a
small number of others, namely, Antinacuhas, Archelius, An-
atochus, and the children of Artaxerxes, who appear to have
been governors in Herat and Southern Bactria, and to have
occasionally assumed the titles and prerogatives of kings.

Hence, the last king of the series, is supposed to have
been overpowered by Axes, a Scythian, who, as it ap-
pears, conquered these countries in company with Maues.
Coins of these princes, and of their successor Azilides, are
frequent. They have the Greek and Armenian inscriptions.
It is not easy to dispute about the date of the coin of the
country about thirty years, from 90 to 60 B.C. Before
their arrival Mithridates the Second, of Parthia, had con-
gregated a great part of Eastern Ariana; and though he was
obliged to give way to the Scythian invaders, the Parthians
did not have to entirely abandon the country, as coins with Parthian names of kings are met with, which, to
judge from the style in which they are executed, must have
been made between 100 and 70 B.C. Professor Lassen, who
has also occupied himself much with the coins of India, con-
siders it as established, from the little that we have of Indian
history, that Vike rnakadiya, king of Ojelein, conquered Kabol
about the middle of the century before our era; but no coin
is found of this person, which is not surprising, as coins were
not introduced into India until the reign of Viceramakadiya
from a victory obtained over the Scythians in the Panaj, and
begins 56 B.C. Though the conquest of Vike
rnakadiya rests only on a supposition, an Indian conquest of the
continent is not an unusual event. The coin of Viceramaka-
diya dates from a victory obtained over the Scythians in the
Panaj, and begins 56 B.C. Though the conquest of Vike
rnakadiya rests only on a supposition, an Indian conquest of the
continent is not an unusual event. The coin of Viceramaka
Hindustan.

The dominion of the family of the Kanakes seems to have
been overthrown at the close of the first century by the irrup-
tion of another nation of Scythians, for about this time a new
series of coins begins, of a different dove and style from any before
current. These are frequent, and are called by the name of
Kanakes, and they seem to have possessed the country
nearly to the close of the fourth century. Their coins are not
bilingual: the only characters are Greek, but they be-
come frequent in a very short time in the inscription which
are quite illegible. On the reverse no mythological deity is
represented, but there are two groups of Mithric
representations of the sun or moon, with mystical
names of these luminaries, also in Greek letters. A few of
the Kanake coins have Siva and the bull on the reverse, so
that it appears that the Hindu religion was not wholly re-
jected, but that the Mithric worship predominated.

It is not ascertained when the family of the Kanakas ceased
to reign in Afghanistan, but as the coins of Shah-
porsk, or Sapor II, are discovered in a succession to the
Kanakes, and Nasberwan, are frequently met with, it is supposed that
the country became subject to the Sassanian dynasty in Persia to-
ward the end of the fourth century. That family politically
lost possession of the country to the time when they were
overthrown by the successful invasion of the Arabs under
the caliphs.

It appears further that though the Sassanian dynasty was
conquered by the Arabs of the western part of Iran, or the
province of Iraq, the possession of the eastern provinces of that family still
was kept up, a footing in the eastern part, or in Afghanistan. That
enfeebled power was unable to hold out for a long time
against the repeated invasions of the Turkoman tribes, who
were in possession of Turan. Some of these tribes settled
during the reign of Ahamshah in the eighth centuries in Afghanistan. Among
them were the Afghans or Assakans, mentioned for the
first time by Ferishta under the year A.D. 681, who
further notices that in the ninth century they inhabited the
mountains of Goor or Ghor, where, after the name of
mountain-regions of the Farangian were comprehended. The

Afghans themselves maintain that they are descended from
Afghan, the son of Irmia or Berka, son of Saul, king of
Israel, and all their histories of their nation begin with
narrating the transactions of the Jews, from Abraham
down to the captivity. After the captivity they allege that
their nation had not yet embraced the new doom of the
Mohammedans were found among them. In the ninth century
a Turkoman family, the Samandiades, succeeded in establishing
a regular government in Afghanistan, which lasted to 976.
We refer to the throne deprived the
Samandigh of the possession of the country, which was taken
possession by of Subuktageen.

Subuktageen must be considered as the founder of that
dynasty which is known by the name of Ghuzechnevides, from
the circumstance of their residing in the town of Ghuzne,
Subuktageen had already made some incursions into the Panj
and with success, and his son Mahmoon, more especially
named the Ghuzechnevides, is considered the first Mohammedan
emperor. He undertook to ascend and laid the country west as far as
the plains of Bengal and the peninsula of Guzerat, but he did not
establish a settled government in any part of the con-
quered countries. Like most of the wars of the nomadic
tribes, his expeditions were considered as a mere
insults than as well-conducted conquests. He plundered
the country, and obliged the princes to pay a sum of money
to withdraw with his army. Those princes whose dominions
had been occupied by the Ghuznevides were forced to con-
tribute a regular tribute. His son Massoud and his successors soon lost
their influence over the countries east of the Indus, and the dynasty of the Ghuzechnevides was overthrown in 1186 by the
Afghans.

The Afghans inhabiting the mountains of Ghor had been
much oppressed by the government of the Ghuzechnevides, and
rebelled in 1186, under their chief Mohamed, who not only
overturned the existing government in Afghanistan, but also
established his dominion in a portion of India, which he
called Hindustan, where the Afghan family of Ghor maintained its
power up to 1286. Meanwhile Genghis Khan had begun his
uninterrupted course of victories and conquests, and about
1224 his armies appeared in Afghanistan, and he took Kandahar
as a regular tribute. His son Massoud and his successors soon lost
their influence over the countries east of the Indus, and the dynasty of the Ghuzechnevides was overthrown in 1186 by the
Afghans.

It appears that the descendants of Genghis Khan, or at least a
Mogul family, kept possession of Afghanistan to 1394, when
Timur invaded the country on his famous expedition to
Hindustan. Though he abandoned Hindustan as soon as he had
conquered it, he handed Afghanistan to his empire of Samarkand, and it seems that princes of his house were go-
vernors of this country up to the time of Baber, who took
possession of Kabol in 1504, which remaining his chief resi-
dence up to 1526, when he overthrew the Afghan dominion
in India. Baber, coincided with the appointment of Af-
ghanistan became a province of the Mogul empire of Lin-
hindustan, and remained so until it was conquered by Shah
Abbas the Great, in about 1626, and annexed to the kingdom
of Persia. It was thereafter some years, until it was
conquered by Shah Abbas II. in 1645. As long as the
government of Persia acted with vigour and treated the
Afghans with justice, the peace of the country was not
threatened. But under the weak reign of Shah Sultan Hosein
Mogul, who allowed each of the Afghan princes to
establish his own government, and the governor of Kandahar committed some acts of injustice against
the chief of the Ghilfe tribe, Moar Veis, who killed the
governor and revolted against the government (1709). Kan-
dahar was besieged by a numerous army, which however was
unable to take the town (1713). After the death of Moar Veis

Ves, his son Meer Mahmood took the power into his hands, assembled a large army, and invaded Persia (1716). Not meeting with any resistance, he advanced to Isphahun, and besieged it in 1722. After a siege of several months, in which the inhabitant of the city, Isphahun, were forced to capitulate. Sultan Shah Husseim resigned his crown to the conqueror, and with Meer Mahmood an Afghan family ascended the throne of Persia. Mahmood soon afterwards became maal, and died in 1725. His cousin Meer Ashursh took his place, the founder of the Ashursh family. Ashursh had not long been occupied by the Afghans. The provinces surrounding the Caspian Sea on the south and west were still in possession of Thamas, a son of Shah Husseim, who was however already reduced to a vassal state, and in 1727 when Nadir Khan found on his way to the south of Persia, he entered his service. He vanquished Meer Aashursh in two battles in 1729, and entered Isphahun. Ashursh lost a third battle near Persepolis in 1730, and was soon afterwards slain. Shah Nadir then conquered Kandahar and the rest of Afghanistan, and, invading Hindustan in 1739, took Delhi, but contented himself with the immense booty he got there, and turned his arms against the Usbecks in Bokhara and Khiva, and the Turks. In 1747 he was murdered in his tent, and one of his generals, Ahmed Khan, became the founder of the Durrance dynasty.

Directly after the assassination of Shah Nadir, Ahmed Khan, accompanied by 2000 or 3000 horse, repaired to Kandahar, where he found a great sum of money sent from Hindustan by Shah Nadir, and himself enabled to gain the goodwill of his countrymen, the Afghans, of whom the Duranses, Beloochees, and the Hazara assisted at his coronation as king of Afghanistan: the Giljes kept aloof. Having secured the ascendency and assembled an army, he crossed the Oxus and captured Khiva, which he took by surprise shortly before his death. In 1748 he reduced the Giljes to obedience, and made himself master of the valley of the Kabul river, whence he invaded the Panjab, defeated the army sent against him, and entered Lahore. He then passed the Sutleje river, and defeated another army at Sirhind, but did not follow up this advantage, but returned to Kandahar. In the following year he established his authority in Herat and Mohob; in 1750 he took Nishapur, and in 1751 he advanced as far as Herat. In 1752 he made an expedition against the Panjab, which he ravaged, and reverted to it Cashmere. By a treaty with the Great Mogul he acquired all the countries of the Panjab and as far east as Sirhind. But in 1756, when the emperor of Delhi had again taken possession of the Panjab, and annexed it to his empire, Ahmed Khan entered Delhi with his army. The emperor was obliged to leave the Panjab and Sinde in his hands. The Mogul government had become so distracted that all its neighbours attacked it, with the concert of the other countries, and the Mahraats took advantage of their expeditions. The Mahraats especially turned these circumstances to account. They for some time had made rapid progress, and in 1757 they took Sirhind and obtained possession of the Panj Jill river Jheelum or Jilun. Ahmed Khan retaken them in 1759, and entered Delhi, which however was besieged by the Mahraats and retaken in the same year. The power of the Mahraats had now attained such a height that all the Mohammedans princes of Hindustan began to fear that their supremacy was drawing to an end, and that they soon would be expelled from the country. This seems also to have been the object of the Mahraats, to judge from the great preparation that they made for that campaign in 1760. The Indian princes therefore called Ahmed Khan to their assistance. He came, and the famous battle of Panipit (7th of January, 1761) put an end to the supremacy of the Mahraats. Ahmed Khan could now have ascended the throne of Delhi, but his object was to possess the possession of the countries which he had formerly been ceded to him, and returned to Kabloo. None of the numerous victories which the British have obtained in Hindustan has more facilitated their conquests in that country than this battle of Panipit, in which they were not prevented by the Five Rivers. Ahmed Khan always succeeded in driving them back into the mountains, but the possession of the Panj Jill remained a precarious tenure. Ahmed Khan died in 1773, and to his praise it must be recorded that the memory of no Eastern prince is stained with fewer acts of cruelty and injustice. The empire which he had erected extended from Herat on the one side to the banks of the Oxus and Cashmere on the north to the Arabian Sea and the mouths of the Indus on the south. It may appear a matter of surprise how such an extensive empire could fall to pieces in such a short time as has elapsed since the death of Ahmed Khan, in 1773. The why of this is that although this empire was as strong as all that the Mogul family had attempted in the course of this as well as so many other extensive empires of Western Asia, which have had the same fate. Some of the conquered countries were left in possession of their native princes, who were generally among those that were obliged to pay a tribute, as Beloochistan and Sinde. To others governors were sent from Kandahar and Cashmere. Whenever the possessors of these countries perceived that their sovereign was unable to compel the tribute, they refused to pay it. The authority of the Afghan sovereigns in their own countries also was not great, as it was dependent on the good will of the chiefs of the different tribes, who frequently paid no attention to the orders of their master, and whom he was not always ready to compel to do their duty. It is evident that such an empire can only be kept together by a sovereignty which is always backed by an army, and always marching from one end of the country to the other, as Ahmed Khan really did. A sovereign gifted with a less active or restless mind soon found that the sovereignty of the country could only be maintained by a standing army, composed of a sufficient army, and always marching from one to the other of the empire, which is the case with all the empires of the east. In 1771 he was obliged to march into the Panjab to recover Mooltan, which had been betrayed to the hands of the Sikhs by the governor. He died in 1773. At his death the second of his sons, Shoojah, was overthrown, and was assassinated. He had to put down several insurrections and rebellions, but the affairs of the Panjab and of Herat chiefly occupied his time and attention. The Sikhs had got possession of the Panjab, and in 1778 he advanced without molesta-

tion to the plains of Kandahar, and got possession in person, and was installed by him as governor of the province. Shah Zeman did not dare to remain long in the Panjab, as his step-brother Mahmood, who was governor of Herat, and acted as an independent sovereign, was always ready to march to Kandahar to get possession of that town, and Zeman was unable to reduce Herat. In 1777 several great men entered into a conspiracy for the purpose of deposing Zeman and raising his brother Shoojah on the throne. The con-

in possession of Kandahar, but he did not succeed. The Shah sent an army to Cashmere, the only province in rebellion, in 1805, and it was subdued in 1806. But at the same time Prince Kysar, a son of Shah Zeman, had been induced to rebel in Kandahar, but was beaten, and submitted in 1808. During this civil war Mahmood had been liberated, and had taken Kandahar. Shoojah marched against and defeated him. Cashmere and the parts of Baluchistan which he had occupied were given by the Shah to Ranjeet Singh, who was defeated and lost nearly the whole army. This event threw the affairs of Shah Shoojah into great disorder. Mahmood captured Kabool whilst the Shah was at Peshawur. In the following year (1809) Shoojah marched against Kabool, but his army was beaten and killed. The Shah, abandoned by all, became a fugitive, and was soon led as a captive to Cashmere.

Shah Mahmood again ascended the throne in 1809. He sent an army in 1811 to attack Cashmere, and to re-establish the supremacy of Sikhs which Runjeet Singh sent to his assistance. Cashmere was obliged to submit, and Shah Shoojah was set at liberty and went to Lahore. Runjeet Singh acquired the fortress of Attock, and since that time the power of the Afghans has ceased on the eastern side of the Indus. In 1815 the Persians were about to attack Herat. Futeh Khan, the vizier of Mahmood, marched against them and defeated their army, but made himself master of the place, dismissing the governor, Khan-i-Khanan. The assistance, Sir William Congreve was defeated of his sight by Kamran, the son of Shah Mahmood, and soon afterwards murdered. The consequence of this event and the state of the Persians in 1815, which they were at that time in process of time was deprived of all its territories except Herat. Several princes of the royal family were raised to the throne, and soon lost it by another revolution, and then several members of the family of Futeh Khan ruled in Herat. In 1820 the kingdom was divided among them in 1824. Dost Mahomed Khan, one of the brothers, succeeded in appropriating to himself the valley of the Kabul river and the adjacent districts in it. He was closely followed by Sir Alexander Burnes, who was compelled to pay tribute to the chief of the Sikhs, and at last he deprived him of his territories, and placed Peshawur under the government of the Punjab. If some valleys in the Himalayas were in possession of the Baluchistan tribes, and the war was reduced, or the settlement was one of the most, the Afghan government was subject to Dost Mahomed Khan.

Dost Mahomed resided at Kabool as his capital city, while Ranjeet Singh governed the Sikhs in the Punjab as envoy from the time in possession of Cashmere and Multan. Dost Mahomed, desirous of securing the friendship of the British government, on the 1st of May, 1836, addressed a complimentary letter to Lord Auckland, who arrived at Calcutta towards the end of June, 1837, and had not heard from the state of India, and he appeared to have soon adopted the notion that the British empire in India was in danger from the intrigues and forces of Russia, Persia, and Afghanistan. On the 20th of September, 1837, Captain Alexander Burnes arrived at Kabul as envoy from the governor-general. On the 24th of December a Russian agent arrived at Kabul, and Burnes was somewhat confounded to learn that he was honourably received by Dost Mahomed. On the 26th of April, 1839, Captain Burnes left Kabul on his return to India, but afterwards, in the presence of Governor General Simla to meet Lord Auckland. Here it was resolved that, as Dost Mahomed was treacherous, and disposed to enter into alliance with Russia and Persia, and could not be trusted, he should be dethroned, and Shah Shoojah sent with an English army to recover the throne of Kabool. Two months before Captain Burnes met the governor-general at Simla, Ranjeet Singh had been joined by Mr. Mountstuart James, with Ranjeet Singh, in which he undertook to prepare the way for the easy advance of the British army through the Sikh country to Kabool. On the 1st of October, 1839, a proclamation of Mr. Simla against Shah Shoojah, and Sir Henry Fane was at that time commander-in-chief of the whole army of India, which was then raised to 208,000 men. Ranjeet Singh, notwithstanding the late treaty, refused to allow the British troops to cross the Punjab, and the principal rendezvous was at Firozepore, on the right bank of the river. The advance of the army on the 20th of February, 1839, began to cross the broad desert towards the Bolan Pass, and reached Dadur, at the foot of the western mountains of Afghanistan, and close to the Bolan Pass, on the 6th of March, when provisions were already so short that the camp-followers were put on the march. The Bolan pass is 60 miles long, winding, rugged, and flanked by high rocks. The surrounding country is inhabited by the wild tribes of Afghans, who live almost entirely by plunder. For several weeks after these events the army were on the march, and reached Quetta, in a fertile valley, after losing a vast number of horses and camels owing to the extreme ruggedness and difficulty of the Pass. At Quetta they expected to find supplies, but there were none; and after some useless negotiations with Meeral Khan of Khelat, to whom the place belonged, the army was compelled to push forward, in a state approaching to famine, to Kandahar, distant 150 miles, which they reached on the 26th of April, having marched 1000 miles since they left Firozepore.

On the 12th of April the Bombay column, after having endurred terrible fatigues and privations, entered the Bolan Pass, and, in spite of considerable opposition, passed through it, and joined the Bengal division on the 4th of May. The army then consisted of about 50,000 men, but the camp-followers had been greatly reduced, but still amounted to 29,000.

Kandahar contained nearly 100,000 inhabitants. The routes led through the mountains and rivers of Afghanistan, which was found to be much more strongly fortified than Sir John Keane had expected. All the gates had been walled up except that opening upon the Kabul road, and it was expected which offered more resistance, to blow down this gateway with powder-bags, and attempt to take the town by assault. On the night of the 22nd of July the gate was blown open with 300 pounds of powder in twelve bags; the storming-party immediately rushed in, and, after a long and desperate attack, the light troops of the British, Afghans, carried the town, and by five o'clock in the morning, or little more than three hours after the gate had been blown open, the strong citadel was also taken, and the British colours waved from the battlements. Hyder Khan, the governor, one of the sons of Dost Mohamed, surrendered in the course of the morning, and was placed under the care of Sir Alexander Burns, who had been knighted previous to the service of the army.

On the 30th of July Sir John Keane marched with the main army from Ghuznee to Kabool; and Mahomed Akber Khan, Dost Mahomed's second son, who held Jel alaba,
having been hastily recalled to assist in the defence of Kabul, Jellalabad was taken possession of by Colonel Wade, who attacked Akbar Khan so vigorously in his retreat that he was compelled to give up all his artillery, baggage, horses, bullocks, and 7,000 rounds of ball-cartridge, which fell into the hands of the British.

As Sir John Keane drew near Kabul, Dehawmed advanced with his third army and camped, and fled with 600 horsemen to seek a refuge beyond the Oxus. At the same time the death of Runjeet Singh was announced. Sir John Keane and Shah Shoojah encamped under the walls of Kabul on the evening of the 6th of August, and on the following day the British officers, by mutual consent, accompanied by the British officers, made his triumphal entry into his former capital; but there was no display of enthusiasm on the part of the natives, whose behaviour was orderly and respectful, but cold and cheerless.

This entry was considered to be complete. The Bombay column quitted Kabul on the 18th of September, the Bengal division on the 20th of October; and, leaving 8,000 men, British and sepoy, besides the Shah’s contingent, to secure him on his throne, the British army returned to India. Sir John Keane returned to England, and was raised to the peerage by the title of Baron Keane of Ghuznee and Cappoquin, with a pension of 20,000 a year.

Mr. MacNaghten, having been created Sir William Mac Naghten, was sent to Kabul as the representative of Sir Alexander Burns as agent to the envoy. In the spring of 1840 insurrections and attacks upon the British outposts began to break out, which, as summer advanced, assumed a bolder character, and were kept down without a great deal of severe fighting. Dost Mahomed was having some assistance returned to Afghanistan, to stir up the insurrection; but as he advanced towards Kabul, he received such severe losses and was reduced to such extremity by the British troops, that he resolved to surrender to Sir William MacNaghten; and, on the 3rd of November, when Sir William was returning from his evening ride, Dost Mahomed rode up to him, alighted from his horse, and presented his sword to the envoy, sought his protection. His sword was returned, and the protection refused. He had ridden many miles from the field of the battle of Purwan Durrah, in which he had been defeated on the preceding evening, straight to Kabul, having been twenty-four hours on horseback. On the 12th of November he was sent to India under a strong escort. Mussoorie, on the British north-west frontier, was assigned to him as a place of residence, and three lacs of rupees, or about 30,000/, were allotted to him as a revenue.

The insurrections continued. At the end of 1840 the British had 16,000 in Afghanistan; in November, 1841, they had 14,000, besides the Shah’s contingent. In May, 1841, Major Pottinger warned Sir William MacNaghten of the dangerous situation of the British, of the insufficiency of their forces, and the weakness of the garrisons in nearly all. He was disregarded both by Mac Naghten and Burns. By the end of September the neighbourhood of Kabul swarmed with predatory bands, and during the month of October the British officers were treated with insolence and insult in their cantonments at Kabul. On the 22nd of November, 1841, Sir William MacNaghten was in the cantonments, and Sir Alexander Burns in his house in the city, when, about nine in the morning, Burns’s house was set on fire, and himself, his brother Lieut. Burnes, Lieut. Broadfoot, and every man, woman, and child on the premises murdered. The British officers in the cantonments seemed to be stupified, and did nothing. Major-General Elphinston at this time held the chief command of the army, but was necessarily confined to all his duties, and could be utterly incapable of acting with the necessary decision and energy in such an emergency. The insurrections continued to increase; the British officers became more confused and indolent than ever. They were murdered in the 23rd of December, in the presence of Akbar Khan, who had invited him to a conference; and by a council of war held on the 29th of December, a treaty was ratified, by which it was agreed to leave behind all the guns except six, to relinquish all the British seats, and give up, in addition, a sum of 6,000 rupees, in bills drawn upon India, but negotiated on the spot by some Indian bankers, for which the whole army was to be escorted to Peshawur; but ultimately Akbar Khan repudiated this treaty and conducted it in safety to Jellalabad, and to Kandahar, and to Peshawur.

On the 6th of January, 1842, the Iills being drawn, and hostages given up, the army left its cantonments at Kabul, and began its retreat, one of the most disgraceful to the British army as well as the most disastrous that has ever been recorded. The whole force was estimated at about 4,500 fighting men, with about 12,000 men of camp-followers, besides women and children.

The work of massacre began immediately; on the 8th of January, Major Pottinger and Captains Lawrence and MacKenzie were given over to Akbar Khan, as hostages for the British officers. The whole British army entered the Khoord Kabool Pass, five miles long, shot in on either hand by a line of lofty hills, with a torrent dashing down the centre, whose course the frost in vain attempted to stop. The country was as bold as it was very great. Lady Sale received a ball in her arm, and Lieut. Sturt, her son-in-law, was mortally wounded. On the 9th the married officers, with their wives and children, and two other wounded officers, were given up to Akbar Khan. On the 10th and 11th the British army made its way through the Kandahar Pass, Durrah Pass, the Dark Pass, and the Tezoon Pass, three miles long, with great loss. On the 11th General Elphinston, with two other officers, fell into the hands of Akbar Khan. On the 12th the army reached Juggululla, 23 miles from Tezeen, and a night entered the Juggululla Pass, two miles long, and exceedingly narrow, precipitous, and difficult. They found the exit from the pass closed up by two strong barries of prickly holly-oak stretching completely across the defile. The army parted, and the right fell into the neighbourhood of Gundumuk, where the final struggle took place, they had only about twenty muskets left. Captain Souter and seven or eight men were taken prisoners. Dr. Brydone and two or three more were taken. The whole time of the retreat the attacks of the Afghans were incessant, the cold was intense, and they were almost entirely without food. Including camp-followers, women, and children, about 25,000 individuals were destroyed.

General Nott held Jellalabad. General Nott maintained himself in Kandahar, and Colonel Palmer, with one native regiment and some artillery, retained Ghuznee, which however was afterwards taken from him, and Palmer and the remnant of his army made prisoners. Akbar Khan on the 18th January, having bested the British forces decisively in the Kyber Pass and when he reached the fortress the beleauring army was dispersed and in rapid flight. General Nott, receiving some supplies in Kandahar, was ready to co-operate with General Pollock and General Nott, and an advance upon Kabul. Shah Shoojah had some friends among the Afghan chiefs, and was able to maintain himself in the Bala Hijar, or citadel of Cabul, after the British had left him to his own resources; but he was assassinated by Shoosh Dowlar and Fatty Malook, and his son, Omar Khan, was proclaimed king by one party and opposed by another.

On the 17th of January, the party of prisoners, consisting of 20 officers, 9 ladies, and 14 children, besides 17 Europeans soldiers, was conveyed to Jellalabad, and the fort of Busssehah, in the Lughman valley, where they were kept till the 10th of April, when they were marched back to a fort at Tezeen, Lady MacNaghten’s baggage having previously been rumaged and plundered of jewels and harts. She had the fort of Jellalabad, on the 29th of April, having bested the Afghans decisively, when she handed it over to the British. At the same time, on the 15th of August, General Nott, at the head of 7,000 men, had left Kandahar for Ghuznee and Kabul. Sultan Jan attempted to stop his march, but sustained a complete
defeat; Ghuznee was retaken, and General Nott continued his advance to Kabul.

On the 25th of August, Akber Khan hurried his prisoners off towards Turkistan, under a threat that he would make presents of them all to the chief of that country. On the 1st of September he reached Barmeen, where they were halted at an old fort till fresh orders were received from Akber. On the 11th of September the khan who had charge of them signed an agreement with five English officers, in which they undertook to receive the proclamation of the British government, to be read to them out of a book in their own language, and to receive afterwards the British flag. The khan then, after due parleying near to Kabul, came in and swore on the Koran allegiance to him and his companions.

On the 15th of September, General Pollock, after some hard fighting at Huttulgulick Pass and elsewhere, having joined his forces with those of General Nott, entered Kabul; and one of his first acts was to send off a party of Kuzzillahs, adherents of the late Shah Shoojah, to the aid of the prisoners, who on the same day had quitted the fort, resolved to fight their way back to Kabul. Pollock, on the 17th of September they were surprised by the arrival of a horseman with a letter from Sir Richmond Skearpe, who was advancing with 600 mounted Kuzzillahs to meet them. They reached the fort at three o'clock in the afternoon, and the next day reached some deserted forts, where they were sheltering themselves from the sun, when, at three o'clock, Sir Rich- mond Skearpe and his troop arrived. 'Our gallant countrymen,' says one of the party, 'was greeted on our side with no less than fifty-two guns, and the overwhelming fire to utter. That we should have escaped unhurt, with so many delicate women, young children, and tender infants, through such numerous perils, fatigues, and privations, and above all from the hands of such merciless enemies as Akber Khan and his Ghilzee confederates, seemed at first too much for the senses to realize.' The march was resumed on the 18th, and on the 20th they were met by General Sale's brigade, the gallant veteran being there in person to receive his long-lost wife and daughter, the widow of the brave Lieut. Sturt. On the 31st of September the happy party marched forward with General Sale's brigade, and entered General Pollock's camp at sunset, amidst the cheers of the soldiers, the congratulations of their friends, and the roar of the artillery, which announced their welcome arrival.

Victory now attended the British standard wherever it was raised, and the Afghan war was at an end. The prisoners had been restored to liberty and their friends, and by a series of well-judged rules and negotiation, all had been retrieved. On the 1st of October, Lord Ellenborough issued a proclamation from Simla, stating that the disasters in Afghanistan having been avenged upon every scene of past misfortune, the war had been declared to be at an end.

On the 12th of October, after having destroyed the fortifications of the Bala Hissar at Kabul, the army began its march back to India, and on the 17th of December, 1842, reached Ferozepore, on the Satluj, where, as Lord Ellenborough expressed it, they were 'within their native boundaries.'

General Sir William Nott died on the 1st of January, 1846, on his estate near Caernarthen, in Wales.

The jurist Africanus, mentioned by Lampridius (Alex. Severus, xii. c. 68), as being connected with the reign of Alexander Severus is a different person from this Africanus: Lampridius has made some blunder, either in the name or in the period to which he assigns this jurist.

E. GEORGIUS (Erythraeus), a Greek painter, who, apparently, from a passage in Vitruvius, may be considered, if not the inventor, at least the first artist who applied the laws of perspective practically in painting. He painted a dramatic scene for Aeschylus in perspective, which was the first work of the kind exhibited to the Greeks; and the contemporary of Aeschylus therefore, he was a man of mature years about 480 B.C.

The words 'scenam fexit,' in the passage in Vitruvius referred to, has been interpreted, he constructed a stage; but this interpretation is shown by the context to be incorrect, the whole passage is as follows: 'When Aeschylus was exhibiting tragedies at Athens, Agatharchus made a scene, and left a treatise upon it. With the assistance of this treatise, Democritus and Anaxagoras wrote on the same subject, showing how the extension of rays from a fixed point of sight should be made to correspond to lines according to natural reason, so that the images of buildlings in painted scenes might be correctly represented upon flat vertical surfaces, some parts should seem to recede and others to come forward.'

This kind of scene-painting was termed Scenography (ενεργονοοηδος) by the Greeks, and was sometimes practised by their architects; Diocles of Halicarnassus, Archelaus of the Typoses, by Masson; Princeps's Note on the Historical Results deducible from the recent Discoveries in Afghanistan; Ireland's Memoir of the Climate, Soil, Produce, and Husbandry of Afghanistan, in Calcutta Asiatic Journal, Ns. 59, 94, 95, 97; On the Wool and Woolen Manufactures of Khorasan, in Calcutta Asiatic Journal, No. 99; Edward Conolly's Notes on the Eusoofy Tribes in Afghanistan, in Calcutta Asiatic Journal, No. 105; Postman's Memorandum on the Silk Trade between Shikarpore and Khorasan, in Calcutta Asiatic Journal, No. 110; Report on the Physical Geography of Seistan, in Calcutta Asiatic Journal, No. 103; Arthur Conolly On a Mission into Khorasan, in Calcutta Asiatic Journal, No. 110; Edward Conolly's Journal kept while travelling in Seistan, in Calcutta Asiatic Journal, No. 102; Dr. Grifffith's Extracts from a Report on subjects connected with Afghanistan, in Calcutta Asiatic Journal, No. 118; Postman's Memorandum on the Trade between the Towns of Shikarpore and Candahar, in Calcutta Asiatic Journal, No. 111; P. C. Josttman's Account of a Tour through Parts of Panjibab and Afghanistan, in Calcutta Asiatic Journal, No. 139; Captain Drummond On the Mines and Ressources of Northern Afghanistan, in Calcutta Asiatic Journal, No. 103; The Balon Pass, in London Geographical Journal, vol. xii.; Forster's Journey from Bengal to England, through the Northern Parts of India; MacFarlane's Indian Empire, 2 vols. 12mo.)

AFRICA NUS, SEXTUS CAECILLIUS, a Roman jurist. Many excerpts from his Nine Books of Questions contained in the Digest [JUSTINIAN'S LEGISLATION, P. C.] Africanus often cites the Responses or opinions of Salvius Julianus, who lived under Hadrian; and he was a pupil or friend of Julianus, and consulted him. (Dig. 25. 5. 15.) The period of his life, according to Graecopius, was 164, under Hadrian, who died A.D. 138, and to that of his successor Antoninus Pius. The fact of Africanus being quoted by Paulus and Ulpianus shows that he was prior to these two jurists. In a passage in Gulus (ii. 219) which has been referred to in order to show that his contemporary reading is probably 'et Sexto,' instead of 'ex Sexto,' and this Sextus may be Sextus Pomponius. As Julianus belonged to the legal sect of the Sabiniians, it is probable that Africanus also did. Anius Gellius (xx. 118) has a brief discussion between Sextus Caecilius, a distinguished jurist, and Favorinus, a philosopher, on the Twelve Tables; and the date of the Twelve Tables is fixed in this discussion as near seven hundred years prior to the time of Gellius. This makes the table probably not the later, but the earlier, the number of seven hundred is too much by a century for the age of Gellius. This error is no objection to our concluding that the Sextus Caecilius mentioned by Gellius is the same as Africanus. The excerpts of Africanus treat of many legal points, and have been well illustrated by Cujicius (Opera, tom. i. tract. 9.)

The jurist Africanus mentioned by Lampridius (Alex. Severus, xii. c. 68) as being connected with the reign of Alexander Severus is a different person from this Africanus: Lampridius has made some blunder, either in the name or in the period to which he assigns this jurist.

PRAETORIUS (Aurelius), a Roman jurist, who, apparently, from a passage in Vitruvius, may be considered, if not the inventor, at least the first artist who applied the laws of perspective practically in painting. He painted a dramatic scene for Aeschylus in perspective, which was the first work of the kind exhibited to the Greeks; and the contemporary of Aeschylus therefore, he was a man of mature years about 480 B.C.
There was another Greek painter of the name of Agatharchus, who lived about half a century later than the above. He was contemporary with Zeuxis, and Plutarch relates an anecdote of the two, how Zeuxis reproved Agatharchus for boasting in company of the art with which he possessed himself — by quietly observing that he (Zeuxis) painted very slowly. This Agatharchus is the painter whom Alcibiades shut up in his house until he had painted certain pictures in it. The circumstance is noticed by Plutarch and by Andoanthes, but there are different accounts of the conclusion of the affair.

(Vitrivius, viii. Proef.; Diogenes, II. 125; Aristotle, Poetic, iv.; Plutarch, Pericles, 13, Alc. 16; Andoanthes, Orat. in Alcid. 7.)

Agatharchus (Ἀγαθαρχος), a Greek historian and poet, who lived under the emperors Justinian and Justinus the Younger. He was a son of Memnonius, and born at Myrina in Asia Minor, about A.D. 550, but he received his education at Alexandria, whence he went in A.D. 556 to Constantinople, and his father seems to have settled during his son's stay at Alexandria. Agathas had commenced studying the law, and afterwards distinguished himself as a speaker in the courts of justice. The title of Scholasticus (Σχολαστής), which some writers give him, and which appears in the MSS. of his work, refers to his profession of advocate, for scholasticus at that time signified an advocate. But notwithstanding the great reputation he thus acquired, he never liked his profession, which he practised, according to him, only for the sake of earning a livelihood: his favourite pursuits were poetry and history. He was esteemed by most of the most distinguished men of the time, and seems to have been rather given to courting the great. Some of his epigrams, which are also extant, contain this description of Agathas: he was a Christian. He died about A.D. 585, in the reign of Mauritius Thrax.

Agathas was the author of the following works: —
1. 'Daphnica' (Δαφνικα), a collection of erotic poems in hexameter verse. It consisted of nine books, but is completely lost. Agathas himself calls it a juvenile production.
2. 'Cycius' (Κύκλος), that is, a poetical anthology, in which he collected the poems of his contemporaries, especially of his illustrious friend Alcibiades, and also a few of his own. The collection itself is lost, with the exception of the introduction, which Agathas wrote. His epigrams, which are still extant in the 'Greek Anthology,' may originally have formed a part of the Cycius: they show that Agathas had considerable poetical talent and wit. 3. 'History of his own time,' is the most important among his works, and is complete, at least as far as he wrote it; for it breaks off abruptly in the twentieth chapter of the fifth book, probably in consequence of the author's own death. This historical work commenced at a late period of his life. It contains the history of the short period from A.D. 553 to 559. He appears throughout this work as a good and honest man, and as a faithful historian. His great faults are ignorance of historical and geographical details, which were at that time little connected with the west of Europe. His language is a tasteless compound of nearly all the dialects of ancient Greece, in which however the Ionic predominates. Among the editions of this work the most important are that of Bonaventura Vulcainus (Lugdun. 1594), those in the Paris and Venice collections of the Byzantine writers, and above all that of B. G. Niebuhr, which forms the third volume of the 'Corpus Scriptorum Historiae Byzantinae' (Bonn, 1828, 8vo.), and contains the good account of the life of Agathas, and also his epigrams.

A'GATION, a native of Sicily, succeeded Demus in the see of Rome, A.D. 678. The Emperor Constantine Pogonatus, brother-in-law of the empress Constantina, about A.D. 680, Agathon sent legates to it, who concurred in condemning the heresy of the Monothelites, who contended that, in consequence of the union of the two natures in the person of Christ, there was in him only one will and one operation, an opinion which Agathon seems himself to have entertained, many prelates, and even by Pope Honorius I. These subtle metaphysical distinctions, to which the minds of the Orientaries were prone, seem to have puzzled at times the more sober and masterly minds of the West. A.D. 682, in the favour of Agathon the usual fine which the see of Rome paid to the emperor at every new election previous to obtaining the imperial confirmation of the bishop elect. The confirmation itself however continued to be required for a considerable time after, if not from the emperor, at least from the Exarch of Ravenna, who was the emperor's representative in Italy.

Agathon died A.D. 682. He is numbered by the Church of Rome among its saints.

(Sandlin, Vita Pontificum Romanorum ex Antiqvis Memoriae Actis, A.D. 530, t. 7.)

AGATHOTES CHIRAYTA (Don, in London and Edinb. Philos. Mag. 1836), the latter being the specific name, an imitation of the Sanscrit and Bengalee names of a plant of the tribe of the Gentianaceae, and so greatly resembling P. Gentianum, that the latter name has been given to it by Buchanan, who has figured it in his 'Plantae Asiatice Rariores,' vol. iii. p. 33, t. 252. It has been known for a great length of time as a remedy in India, but has only recently been introduced into European practice. Indeed it has not yet been received to the same extent as the well known pharmaceutical plants of that of Edinburgh: that it merits however a more extended use is certain. It is probable that even in India two distinct plants, both gentianaceous, are designated by the name Chirayta: one being the A. Chirayta, and another the A. Hancora, the last two so termed. The smaller of the two is that which is here treated of. Continental pharmacologists have had sometimes the one, sometimes the other, supplied to them. Hence very erroneous accounts are met with of the habitations and physical characters of the Chirayta. Geiger describes it as a perennial plant, native of Egypt as well as India, and of larger dimensions than the plant now introduced. The genuine Chirayta is an annual plant, about three feet high, flowering in the rainy season. It is not difficult for collecting it is just when the flowers begin to wither. When dried it has an intensely but agreeable bitter taste, and is destitute of aroma. The root is possessed of the greatest bitterness. The bitter principle is readily impregnated with water: it is a diuretic, and is used as a remedy in dropsy. The plant the continental chemists analysed, it seems best to follow the analysis of Mr. Bartley, whose specimens must have been genuine, having been furnished by Dr. Wallich. According to this chemist, it contains a free acid, a bitter resinous extractive, with much gum, and chlorates, with sulphates, of potash and lime. No alkaloid has been detected in it; what is therefore sold as a sulphate of chirayitane is well known to be only the disulphate of quina. In regard to the pharmaceutical virtues of the plant, in every case of diarrhoea, failure of appetite, or the duration of its function, are anything but beneficial. It is one of the most depressing medicines, and is best employed in the cold infusion a pint of warm water is to be condensed, as this causes most distressing headaches. Even to form the cold infusion a pint of water should not stand more than twenty minutes on half an ounce of the bruised plant. The tincture is a grateful addition to it.

Chirayta possesses the general properties of bitter herbs, but has at the same time some peculiar to itself, which fit it for a variety of medicinal purposes. Unlike most other tonics, it does not constipate the bowels, but tends to produce a regular action of the alimentary canal, even in those subject to habitual constipation. During its use, the bile becomes more abundant and healthy in character. The patient is more cordial and cheerful, and everyday increase of strength, the function of filth, is much restrained by its use. These qualities fit it in a most peculiar degree for the kind of indigestion which occurs in gouty persons. It may, when necessary, be associated with alkaline preparations or with acids; the latter are generally preferable. The same remark applies to its employment in the treatment of scrofula, in which alkalies are so freely and often injudiciously employed. As a remedy against the languor and debility which afflicts many persons, it is deeply recommended; nothing usual in the treatment of this plant. It may be taken twice or even more frequently daily, for a considerable time; then discontinued, and afterwards resumed. Children take it more readily than most other herbs. It is found to be a very efficacious remedy in India against intermitents, particularly when associated with the Guilandina邦东, or Caranga nuts. The debility which is apt to end in dropsy is often speedily removed by infusion of Chirayta; to which is added the tincture formed of it with equal parts of an infusion of Cascara. A remedy of great value has procured for it the name of worm-seed plant. The extract is given with great benefit in some forms of diarrhoea and dysentery, particularly if combined with ipecacuan, the emetic tendency of which is well known, and probably makes it more effective. It is more probable that in the present day is said to yield the
AGLAOPHON of Namur. Whencesoever obtained, this oil possesses great virtues. It is much used in India against rheumatism. It has the power in a most remarkable degree of preventing the hair of the head from falling off after acute diseases, such as pleurisy, or after confinement or protracted nursing. With it even restores it after it has fallen off. But it must be strong and pure; not the diluted feebly oil sold by perfumers under the name of oil of grass.

AGNOSTOS. [Agnostos.] There were two distinguished Greek painters of this name, who were probably related. Bogtius supposes that the younger was the grandson of the elder Aglaophon, and the son of Aristophon, the brother of Polycleitos. The latter was born in a little island off the coast of Thassos, where his son Polycrates was also born. Aglaophon's greatest distinction is that of having been the father and the instructor of Polycrates, who is the first painter recorded in history who attained great fame. Quintilian is the only writer who speaks of the style of Aglaophon, but he indiscriminately couples him with Polycrates. He says, 'Notwithstanding the simple colouring of Polycrates and Aglaophon, which was little more than the crude beginning of what was afterwards accomplished, many ravers, certainly with some affection, preferred their works to those of the greatest masters who succeeded them.' There can be as little doubt that this passage refers to the elder, as that which following from Cicero refers to the younger: Cicero says, talking of Apelles: 'Aglaophon and Apelles, both great masters, were all different in their styles, yet each was perfect in his own style.

None of the works of the elder Aglaophon are particularly mentioned, unless the Winged Victory spoken of by the scholiast on the Birds of Aristophanes (v. 675) may be attributed to him.

The two pictures of Alcibiades mentioned by Athenaeus must have been by the younger. After Alcibiades, says Athenaeus, returned to Athens a victor at the Olympic games, he exhibited two pictures of himself, one representing Olympias and Pythias crowning him, and the other he was painted extremely beautiful, lying on the knees of Nemea. Plutarch attributes the latter of these pictures to Aristophon, the brother of Polycleitos, a painter, of whom nothing is known besides, but as the account of Athenaeus accords better with the time, it is more probably correct, at least under the supposition that there were two artists of this name. The beautiful horse spoken of by Adian was probably the work of the younger Aglaophon.

(Suidas, Ἀγλαόφων; Quintilian, Inst. Orat. xii. 10. 3; Athenaeus, xii. 534; Plutarch, Alcibiades, 16; Cicero, De Anima, 31. 6; Adian, De Anim. in Epilo.)

AGNOSTUS. [Agnostos.] A genus of Crustacea usually found with Anaspis Buchi and other trilobites in the lower Paleozoic strata. (Brongniart.) Called Battus by Dalman. It abounds near Llanddilo and Christiania.

AGNOETHERIUM, a fossil genus of Mammalia. (Kaup.)

Agricultural Institutions. In this article it is proposed to give some account of various institutions for the improvement of agriculture, beginning with the Board of Agriculture.

This semi-official institution was established chiefly through the exertions of the late Sir J. Sinclair, and was incorporated in 1793. It was annually assisted by a Parliamentary grant. One of the first acts of the Board was to commence a survey of the English counties on a uniform plan, which brought out, for the information of the class most interested in adopting them, improved practices, originating in individual enterprise or intelligence, and which were confined to a particular district. The 'Surveys' are many of them imperfectly executed, but they were useful at the time in developing more rapidly the agricultural resources of the country. During the years of scarcity at the end of the last and beginning of the present century the Society took upon itself to suggest and, as far as possible, provide remedies for the dearth, by collecting information and making reports to the government on the state of the crops. The statistics which the Board collected were also at times made use of by the ministers of the day, and are still used by the Board in connection with his schemes of taxation. The Board encouraged experiments and improvements in agriculture by prizes; and it naturally exercised considerable influence over the provincial agricultural societies.

The Board of Agriculture was reorganized in 1816. The Smithfield Cattle Club, which has been in existence half a century, and some of the provincial agricultural societies, especially the Bath and West of England society, which commenced the publication of its 'Transactions' nearly seventy years ago, have been very useful in promoting agricultural improvement. Until the last few years, the exertions of Agricultural Societies have been too exclusively devoted to the improvement of stock.

With the establishment of the 'Royal Agricultural Society of England' a new era commenced in the history of institutions for the improvement of agriculture. When the society was founded, in May, 1838, consisted of 468 members. At the first anniversary, in May, 1839, the number of members had increased to 1104; in May, 1840, to 1770; in May, 1841, to 3564; in May, 1842, to 5246; in December, 1841, 5592; in May, 1842, 5844; and by the following May, 1843, the number had been increased by the election of 1436 new members. At the sixth anniversary of the Society, in May 1844, the number of members was 6927, of whom 274 had been elected in the preceding three and a half months; and there had previously been struck off the list 249 names of members who were either dead or had not paid their subscriptions. The number of life governors (who pay an admission fee of 50l.) was 97 in December, 1844; and there were 208 annual governors, who pay 5l. for admission, there were 470; and of annual members, who pay 1l. yearly, there were 6827. At the above date the funds property of the Society amounted to 7700l., and the number of members was 6000. The 26th of March, 1840, the Society received a charter of incorporation, on which it assumed the designation of the 'Royal Agricultural Society of England.' By the 22nd rule of the Society, 'No question shall be discussed at any of its meetings on a political topic; nor shall any new business be brought forward, or pending, in either of the Houses of Parliament,' and this rule is made permanent by the charter of incorporation.

The objects of the Royal Agricultural Society, as set forth in the charter of incorporation, are: 1. To embody such information contained in agricultural publications and in other scientific works as has been proved by practical experience to be useful to the cultivators of the soil. 2. To correspond with agricultural societies and other bodies, at home and abroad, and to select from such correspondence all information which, according to the opinion of the Society, may be likely to lead to practical benefit in the cultivation of the soil. 3. To pay to any occupier of land, or other person, who shall undertake, at the request of the Society, to ascertain by any experiment how far such information leads to useful results in practice, a remuneration for any loss which he may incur by so doing. 4. To encourage men of science in their application to the improvement of agriculture, by giving them either a grant of land, or a share of the proceeds of the construction of farm-buildings and cottages, the application of chemistry to the general purposes of agriculture, the destruction of insects injurious to vegetable life, and the eradication of weeds. 5. To promote the discovery of new and other useful animals, bird and other vegetables, useful to man, or for the food of domestic animals. 6. To collect information with regard to the management of wood, plantations, and fences, and on every other subject connected with rural improvement. 7. To take measures for the improvement of the education of those who depend upon the cultivation of the soil for their support. 8. To take measures for improving the veterinary art, as applied to cattle, sheep, and pigs. 9. At the meetings of the Society by the distribution of prizes, and by other means, to encourage the best mode of farm cultivation and the breed of live stock. 10. To promote the comfort and welfare of labourers, and to encourage the improved management of their cottages and gardens.

The Society has already directed its attention to nearly all the objects above mentioned. The country meetings which take place annually in July, have perhaps been more serviceable in stimulating agricultural improvement than any other meetings by the society; and the Board of Agriculture, by the arrangement adopted by the society upon each part of the country in succession, and by exciting the attention of each district to the objects which the Society is intended to promote. England and Wales are divided into nine great districts, and a place of meeting in each district is appointed for the Board, of which the first meeting was held at Oxford; and others have been successively held at Cambridge, Liverpool, Bristol, Derby, and Southampton. The meeting for 1845 will be held at Shrewsbury; in 1846, in some town in the Northern district; and in 1847, the circuit will be completed by the meeting being held in the
South Wales district. The value of the prizes distributed in 1838 amounted to 1790/. It was increased to 2800/ in 1844, and continued to the Southampton meeting, to 1400/.

The show of agricultural implements at Derby comprised 700 different articles, and the aggregate value of implements, according to the selling price of each, declared by the makers, was about 7400/.

There can be no doubt that the agricultural societies are making material progress since the establishment of the Society. The opportunity of contrasting and estimating the utility of various implements used for similar purposes in different districts or in different soils, cannot fail to extend improvement from one district to another and all the more to prove that the establishment of such institutions is extremely beneficial. The Society has already published 'Proposals for a Royal Institute or College of Agriculture and other branches of Rural Economy.' There is the Slithropian Professorship of Rural Economy in the University of Oxford; and at the University of Edinburgh there are professorships of agriculture and agricultural chemistry; and at the University of Aberdeen there are lectures on agriculture.

The botanical, geological, and chemical professorships and lectures in the different universities are however, to a certain extent, subject to the same sort of drawbacks as the similar establishments of such institutions as the one at Grignon in France, young men are sent out as a great expense to pupils to farmers in the counties where the best system of agriculture is practised. In the case of all the most prosperous farmers in the United States, the income from the sale of their produce is sufficient to enable them to purchase farm books and periodicals at any cost. It is therefore questionable whether the benefits of the agricultural museums established under such institutions as the one at Grignon in France, are limited to the purchase of agricultural books and periodicals; but although this may be a good plan for obtaining practical knowledge, it is imperfect as regards acquiring a knowledge of the scientific principles of agriculture. The Earl of Ducie has established a model or example farm on his estate at Trenchard, Devon, which is to be of considerable local advantage. Such a farm, says Mr. Daubeney, if well conducted, cannot fail to benefit the farmers round about; by exhibiting to them improved implements; by introducing a greater economy of labour, demonstrating for the practical farmer the advantage of employing labourers indefatigably in the promotion of this object, and probably would have succeeded, but for his premature death. In the projected Agricultural College and model Farm at Cirencester, there will be a scientific course of lectures and scientific, under a person thoroughly acquainted with the management of a farm, associated with a professor of chemistry, mechanics, 

Schools of industry, similar to the one established by the late Rev. W. L. Rams at Winkfield, may be made the medium of imparting an acquaintance with the principles of agriculture, which at present the labouring classes do not usually obtain; and they obviate the objection that a child who remains long at school is unfit for hard labour on the Winkfield schools there are attached about four acres of good land; and under the guidance of so accomplished an agriculturist as the late Mr. Rham the scholars enjoyed the advantage of pursuing all the details of the most skillful husbandry, and undergoing a course of training in garden and farm management of no ordinary excellence. Schools of a similar kind to the one at Winkfield have been established at Ockham, near Ripley, in Surrey; at Lindfield in Sussex [Alwyn and William, C. S.]; at Horsham, near Eynsford; and at Tunbridge Wells. On Mrs. Davies Gilbert's estate there is a school of manual labour, and the principle on which it is established might perhaps be made conducive on a large scale of the two objects, namely, the dissemination of the elements of learning and of fitting them by proper industrial training to become expert and industrious in field and garden work. At the school here spoken of, the master is paid one penny per week for each boy; but the chief employment of Mrs. Davies Gilbert's estate there is a school of manual labour, and the principle on which it is established might perhaps be made conducive on a large scale of the two objects, namely, the dissemination of the elements of learning and of fitting them by proper industrial training to become expert and industrious in field and garden work. At the school here spoken of, the master is paid one penny per week for each boy; but the chief employment of
the master arises from the labour of the boys on the school land. Their time is divided into two portions, one part of which the master devotes to their instruction in reading, writing, and arithmetic, and the other in keeping the farm and in cultivating his land. (Committee of Council on Education, 1844.)

In Ireland the government affords direct encouragement to agriculture by granting financial assistance to the Board of National Education. The persons who are trained for the office of teachers in the national schools are required to attend the lectures of a professor of agricultural chemistry; and during a portion of the time occupied in preparing for their future duties they are provided with model farms at Clonmel, seven, where they are lodged and where, during, five mornings, they attend lectures on the principles of agriculture; and an examination subsequently takes place. Once a year the veterinary surgeons of various local boards are instructed in the operations required by the various causes which are continually occurring on the farm. Others are appointed to attend to the gardens, and to the following departments: woods and plantations; inspection of repairs taking place on the premises; making of starch, cheese, and other articles; the phonography, book-keeping and the accounts. A daily register is kept of the amount of the manure obtained from the cattle of any kind. A pupil newly entered is appointed to act with one of the pupils of three years' standing, and all are expected to make a report, in the presence of the committee, of whatever has been done during the week in their respective departments. The professor, who presides over the practical part of their education, explains on the spot the proper manner and system of operations. The students attend two or three lectures on these different processes at the time when they are in actual progress. The professors in each department render their courses as practical as possible; the professor of botany by herbaceous and the professor of chemistry by geological excursions; the professor of mathematics, by exercising in the plan he has pointed out, the survey and measurement of certain portions of land. After two years' training in the theory and practice of rural economy, the pupils undergo an examination, and if approved as a candidate for the degree of bachelor, a diploma is granted, which certifies to the capacity of the pupil for fulfilling the duties of what may be styled an 'Agricultural Engineer.' Institutions designed for the improvement of agriculture, and supported by the state, have been established in most parts of Germany. In Prussia there is a public model farm and agricultural academy in nearly every province. The most important of these institutions is the one at Möglin, in Brandenburg, about thirty miles from Berlin, which was founded by the late king. Von Thaer was at one period the director. The establishment consists of a college and a model farm of 1200 acres. When visited by Mr. Jacob, in 1820 ('Agricultural and Literary Journal'), the farm was divided into three parts, and the profits arising therefrom, after being applied to their maintenance, were distributed amongst the pupils; one for mathematics, chemistry, and geology; one for the veterinary art; and the third for botany and the use of the various vegetable productions in the Materia Medica, as well as for entomology. Attached to the institution there was a botanical garden, arranged on the Linneas system; an herbarium; a museum containing skeletons of domestic animals, models of agricultural implements, specimens of soils; &c. The various implements were made in workshops upon the farm, and the pupils were expected to acquire a general notion of the modes of constructing them. The sum paid by each pupil was very high, not less than 80l. a year.

At Hohenheim, in the kingdom of Württemberg, two leagues from Stuttgart, a model farm has been appropriated as an agricultural college. The quantity of land attached to the institution is about 1000 acres. The pupils are of two grades, and those belonging to the superior class pay for their board 150 florins, and for their books and services 32l.; the pupils of the inferior class pay for their board 60 florins, and for their books and services 37l., and extra expenses make the annual cost about 50l. Natives of Württemberg are admitted at a lower rate than the subjects of other states. The higher class of students do not, as at Grignon, take part in the actual labours of husbandry; but they are brought into contact with the practical side of instruction, and are very carefully instructed. Lectures are delivered by twelve professors on the following subjects:—Mathematics and physics, chemistry and botany, technology, tillage, and other departments of rural economy, and the veterinary art. The objects are to familiarise the students with the various functions that they can be either attended in two halves or three or four. In the former case much preliminary information must have been acquired. There is attached to the institution
a small botanical garden; a museum of zoological, botanical, and mineralogical objects; skeletons of domestic animals; collections of seeds and woods; and a library of works on rural economy. The establishment also comprises a manufactury of beet-root sugar, a distillery, and a potato-mill, and there is an apartment devoted to the rearing of silkworms. A part of the farm is reserved for experiments. The second class of students do the manual labour, but they are nearly maintained at the expense of the institution, and, when they can supply the farm labour, they have the opportunity of attending the lectures at the college.

In Bavaria the king has given up the domain attached to the royal palace of Schleisheim for the purposes of a model farm; and the king has been in selecting it much below the average standard of fertility, which, as well as land of extraordinary productiveness, should be avoided. It is on a much inferior scale to the establishment at Hohenheim. In 1840 there were twenty-one scholars who paid about 15s. a year, and eleven who paid about 6l. The latter are merely field-labourers; and those who belong to the upper class are about the same grade as the second class at Hohenheim.

There are agricultural institutions supported by the state in several other countries of Europe.

(On public Institutions for the Advancement of Agricultural Science, by Dr. Daubeny; Dr. Daubeny's Lecture on Institutions for the Better Education of the Farming Classes, address delivered at the Agricultural College at Cirencester, delivered at Oxford, May 14, 1844; Journals of Royal Agric. Soc. of England; Dr. Ludlow's Gardener's Chron. and Agric. Gazette, &c., &c.)

AGRICULTURE (from the Latin Agricultura). The economy of every country is based on the number of branches of industry is the subject of the following remarks.

The question has sometimes been propounded whether agriculture or manufactures are more useful to a state, or, in other words, whether agriculture or other branches of industry contribute most to the wealth of a state; and whether a state should give more encouragement to agriculture or manufactures. Such questions imply that there is something which essentially distinguishes manufactures from agriculture; and also that there is something which essentially favours the success of agriculture. Agriculture is the raising of vegetable products from the soil, which are either consumed in their raw state or used as materials on which labour is employed in order to fashion them to some useful purpose. Manufactures, in the ordinary sense of the term comprise the various modes of working up the raw products of agriculture and mining. So far there is a distinction between agriculture and manufactures; agriculture is auxiliary and necessary to the other. In the popular notion, agriculture is the raising of these two principal products from the ground and the working up of the product into another form, constitutes an essential difference between these two branches of industry; and accordingly agriculture and manufactures are often spoken of in opposition or contrast, and they are often viewed as standing in a hostile opposition to one another. But such a distinction between agriculture and manufactures has no real foundation.

The agricultural products which are articles of food—as bread, the chief of all—are essentials, and the industry of every country is directed to obtaining an adequate supply of such articles, either from the produce of the country or by foreign trade. Some of the various kinds of grain which are used as food are the principal and daily articles of diet in many countries. Agricultural articles which are employed as materials out of which other articles are made, such as cotton, are only in demand in those countries where they can be worked up into a new and profitable form. The varieties of soil and climate render some parts of the world more fit to produce grain, and others more suitable for cotton. Even since the earliest records of history the people of one country have exchanged their products for the products of other countries; and if the matter were simply left to the wants and wishes of the great majority of mankind, no one would trouble himself with the question of the relative superiority of the process by which he produces grain or cotton, and the art by which his cotton is turned into an article of daily utility, and the age of his cotton back to him in its initial form to be exchanged for grain or more raw cotton. He might not perceive any essential difference in the process of turning the earth, committing the seed to it, and reaping the crop at maturity; and the process by which the raw material which he has produced, such as flax or cotton, is submitted to a variety of operations, the whole of which consist only a giving new forms to the material or combining it with other materials. In both cases man moves or causes motion; in the one case the relative place of the particles of matter, and in the other case it is the relative place of the particles of matter combined with other particles of matter. So that if the amount of the direct labour of hand is to be the measure of the importance of agriculture, manufacturing processes and manufactures than manufactured articles are. Some branches of agriculture, such as wine-making, indeed belong as much to manufactures, in the ordinary sense of that term, as they belong to agriculture; and wine is in part of the process of wine-making; but the making of wine is equally essential. There are some few agricultural products which receive their complete value from what is termed agriculture; but the making of flour or wine or cloth is a manufacturing operation, as the word manufacturer is understood in the dictionary.

But it is a question in which all those branches of agriculture which are directed solely to the production of food.

Now if the question be, which of these branches of industry adds most to wealth, or, in other words, is most useful to mankind, the answer must be, they are all equally useful. If it be urged that some are of more intimate necessity than the others, inasmuch as food is essential, and therefore its production is the chief branch of industry, it may be replied, that this is not the case, because the raising of these two principal products from the ground and the working up of the product into another form, constitutes an essential difference between these two branches of industry; and accordingly agriculture and manufactures are often spoken of in opposition or contrast, and they are often viewed as standing in a hostile opposition to one another. But such a distinction between agriculture and manufactures has no real foundation.

Though it is an idle question to discuss the relative value of any branches of industry, when we found the comparison upon a classification of which it rests on no real difference, and leave out of the question their aptitude to minister to our wants. One might discuss the relative value of the manufacture of scents and perfumes, and the manufacture of wine and beer; and then the question of the comparison of value might be the number of persons who use or wish to use the two things, and the effect which the consumption of scents and perfumes on the one hand, and of wine and beer on the other, will have on the consumers and the condition of those who produce them.
of hunting, mining, are not due to agriculture, even in the sense in which the advocates of this theory understood the term agriculture: and further, a large part of agricultural products receive most of their value from other labour besides agricultural labour; whilst the materials of which the products of agriculture are composed, must undergo a manufacturing process before it becomes bread. But the greatest part of the corn that is produced has little value in the place where it is produced: it obtains its value by being transported to another place where it is consumed, and which is capable of limiting it, for the purpose of its selling price.

Lastly, the corn is of no value even when it has been removed from one place to another, unless it has been removed to a place where it is wanted by those who are not raising it. Hence the producing community is bound to give it to the consuming community.

The value of the corn is circumscribed ultimately on the labour and the wants of those who do not concern themselves about its production.

If those who possess political power were free from all prejudices and all motives of self-interest, or what they suppose to be their interest, there would neither be encouragement nor discouragement given to any branch of industry, and least of all to agriculture. If taxes must be raised, they would be raised in such a way as would least interfere with the free exercise of all branches of industry; and they would not be raised upon raw products of any kind. It is the business of a State to find sufficient means, at the least possible cost to the whole community, for defence against foreign aggression, for the administration of its government, and for the ultimate interest as its direction and superintendence.

To ascertain what these matters are to be and how they are to be effected, belongs to the subject of government; and the sphere in which the State should limit its activity cannot be exactly defined. But there is one thing certain, that there is a difference from many matters: this is:—If men are not interfered with, they will employ their labour and capital in the ways which are most profitable to themselves; and each man knows better how he can employ himself profitably than anybody else can, or any government can, whether such government is of one or many. Agriculture is no exception to this general principle; and there is no reason of public interest that the government should either encourage or discourage it. In order that the State may be able to benefit by the development of agriculture, it is necessary that it be free from all restraint, and that it be also free from the equally injurious influence of special favour or protection.

But no governments have ever let the things alone which they ought not to have meddled with; and agriculture has been subject perhaps to more restrictions than any other branch of industry. The interference with agricultural industry lies at first sight appears. Land is an essential element of a state: it is the ground for all the products of agriculture. Now the political constitution of every country is intimately connected with the nature of the landed property; and if we would truly trace the history of any nation from the earliest period, we shall find that the development of the political and social notions of the law of property in land. In this country for instance it is easily shown that the present mode in which land is held and occupied is the result of those feudal principles which were established, or confirmed and extended, by the Norman conquest of England. The various modes in which land is held by the owner and occupied by the cultivator, the modes in which it may be alienated or transmitted by or by descent, the burdens to which it is liable either on any change of ownership, are all important elements in estimating the degree of freedom which agricultural enjoys.

The political constitution of a country also materially determines whether the land shall be cultivated in large patches of portions, whether owned by a numerous body or owned by a few; there may also be positive laws which affect the power of acquiring land or disposing of it; and these circumstances materially affect the freedom of agriculture and its condition. The political constitutions of countries, so far as they are productive of a medium generation of the present generation find something transmitted to us which our predecessors have been labouring to amend or improve; they in like manner received it from their predecessors at the beginning of the series we cannot ascend to.

Such as have sometimes an object purely political, that is to say, a law may be passed which shall have a direct object, not agricultural, and yet it shall indirectly affect agriculture. Any statute or law which in any way either prevents large masses of land from being owned or cultivated by individuals, or which results in a great subdivision of land among owners and occupiers, has an indirect effect on agriculture. Those who cultivate on a small scale cannot enter into the market in competition with those who cultivate on a larger scale. State which consists solely of small landowners must be a feeble political body, and the amount of surplus produce which can be raised will be small. Such a community, if it has not the resources of foreign commerce, will in seasons of scarcity pay higher prices. The more political bodies depend on a variety of considerations, but whatever it may be, the profitable measure will be practically determined in a country where land can be freely bought or hired, and where capital and labour are abundant. In such a country, and where there is a certain amount of land, it is probable that circumstances will produce farms of every size from the smallest unprofitable holdings to the largest farms which can be managed with profit. Where land is hired by the cultivator, it is an essential condition to good agriculture that there should be farms to hire and dispos of it as be pleases either during his lifetime or at his death. Though this general principle must be admitted, it may still be laid down as a safe rule that there are admitted to be within which the power of any man's power over his property in land ought to be circumscribed. He should not be allowed, for example, to determine the line of life of the person or class of persons shall enjoy his land, and to limit the power of alienating it; unless it may be when his property is given for public purposes of unquestionable utility. For with regard to the public utility of purposes, the State ought to apply the property to new and useful purposes. There are therefore limits which ought to be placed to a man's power over his land. But such limits should not in any way limit the productive use that can be made of the land; and therefore, whatever may be the limit, is to prevent any large amount of land from being withdrawn permanently out of the market. In a rich country, where great fortunes are acquired by commerce and manufacturing industry, there are always men who wish to invest money in land, and it is for the public interest that there should be opportunities of making such investments.

The tenure of land in any country may be unfavorable to the improvement of its agriculture. If the object is to encourage agriculture in the only way in which a State can profitably encourage it, all restrictions that arise from the peculiar tenure of land should be removed. But the mode in which land is held may have a political character, and this may be an obstacle to the agricultural improvement. It is, however, necessary for its improvement. It might be considered that in this country it would be politically useful to forbid those large accumulations of land in the hands of individuals, a condition which is accompanied with a diminution in the number of small landowners. If it were with a view to enact a law that should limit the quantity of land that a man could cultivate, it would be very unwise in another points of view; and such a law would also easily evaded. The Agrarian laws of Rome only apply to individual free cultivators; for the larger farms were cultivated by slaves. Though these laws were not an interference with private property, as the term is properly understood, they interfered with the profitable employment of capital; and they failed in accomplishing their principal object. Under the article ALLOTMENTS, P. C. S., of the gradual decrease of small farms in England and their consolidation into large farms, a process which will certainly take place in all countries where there is no positive obstacle, whenever capital is become abundant.

The political constitution of a State may therefore encourage or discourage agriculture; and laws may be from time to time enacted which shall have the same effect. Such laws have sometimes an object purely political, that is to say, a law may be passed which shall have a direct object, not agricultural, and yet it shall indirectly affect agriculture. Any statute or law which in any way either prevents large masses of land from being owned or cultivated by individuals, or which results in a great subdivision of land among owners and occupiers, has an indirect effect on agriculture. Those who cultivate on a small scale cannot enter into the market in competition with those who cultivate on a larger scale. State which consists solely of small landowners must be a feeble political body, and the amount of surplus produce which can be raised will be small. Such a community, if it has not the resources of foreign commerce, will in seasons of scarcity pay higher prices. The more political bodies depend on a variety of considerations, but whatever it may be, the profitable measure will be practically determined in a country where land can be freely bought or hired, and where capital and labour are abundant. In such a country, and where there is a certain amount of land, it is probable that circumstances will produce farms of every size from the smallest unprofitable holdings to the largest farms which can be managed with profit. Where land is hired by the cultivator, it is an essential condition to good agriculture that there should be farms to hire
which permit and require the employment of large capitals. It is also necessary that he who hires the land shall be able to secure the use of it for a period long enough to induce him to cultivate it in the best way, and to make those improvements the possession of which is made a generally essential and equally important condition that he should not be restrained in his mode of cultivation. Small farms, short leases, or uncertain terms of years, and conditions which prescribe or limit the mode of cultivation, will infallibly produce bad agriculture.

The productive power of agriculture is not free in any country when the agriculturist is fettered by restrictions upon the use of his produce; when the restrictions imposed by his own State and by another State prevent him from selling his produce where he can, or whether they are imposed by another State which refuses to receive his surplus produce. In neither case will agriculture attain the development of which it is capable. France furnishes the free intercourse between the different provinces of the kingdom was once imposed by many restrictions, and corn could not be taken even from one province to another. [France, P. C., p. 431.] The consequence was that agriculture was in a wretched condition, but it improved when the restrictions were removed. The history of all countries shows that the interference with the power of disposing of agricultural produce has been unfavourable to agriculture, and consequently injurious to the whole community. Nor is the agriculture of a country which prevents the land occupiers from taking their produce to heavy taxes, direct or indirect. Such taxes raise the price of agricultural produce, and so far diminish the power of persons to buy it; they also increase the amount of capital requisite for cultivating a piece of land, for the payment of the taxes is not always in the form of money, contingent on the amount of the produce when the produce is sold converted into money. Payments the amount of which is fixed with reference to the productive powers of the land or which depends on the actual amount of produce, may either be in the nature of rent, that is, the amount which a cultivator agrees to give to the owner of the land for the use of it; or they may be payments which the land owes to some person or persons not the owner or occupier, and quite independent of the payment due to the landlord: to this second class of payments belong. The cultivator of the Roman Public Land paid the State a tenth of the produce of arable land, and a fifth of the produce of land planted with productive trees. But this second class of payments is on obstacle to improvement, for the occupier must lay out capital in order to increase the produce of the land; and it will often happen that he pays the tenth of the produce before he has got back his capital, and long before the reclaim of any profit. The money payment which a man makes to the owner of the land is not to use it; is not to be the value of the produce which remains after all expenses of cultivation and all costs and charges incidental to the cultivation are paid, and the average rate of profit also returned on the investment of capital; at least this is the general notion which the amount of rent under ordinary circumstances will be determined. It may therefore be as low as nothing. How high it may be depends on various circumstances.

In a country where the property to the land is free from all restrictions, it may in a given time reach the limit of its productive powers. In a country which has a considerable extent of surface and variety of soil, this limit may not be reached for many centuries, because improvement in agriculture is slower than in almost every other branch of human activity. The best lands which are both occupied and carefully cultivated, as in America; the inferior lands will in course of time be resorted to, and the result of modern science will be applied to improve the worst parts. An agricultural country, or a country which produces only raw products, and has no manufactures, will have reached the limit of its productive powers when it has raised from the soil all that can be profitably raised. Whether it will have a large surplus agricultural produce or not, depends entirely on the degree of freedom of the farms; but in either case the country will have attained the limit of its productive powers under the actual circumstances in which the agriculture is carried on.

But a country which also abounds in manufacturing industry may continue to extend its productive powers far beyond the limits of its agricultural produce. Part of the agricultural produce will be food, but when the producible amount of food has reached its limit, the productive power of manufactures has just begun to be felt, and it is the balance between agriculture and manufactures. Great Britain, for instance, might not be able to raise more food than is sufficient for its actual population, but Great Britain could supply the world with cotton-cloth and hardware. A country of any considerable extent with a fair proportion of good soil will always be to a considerable extent an agricultural country, for, however much its other resources may be developed, it will always be as profitable to cultivate the good lands of such country as to import foreign grain, the price of which is increased by the cost of carriage and contingent expenses. The balance which all countries, with very rare exceptions, have in the food population not employed in agriculture, when foreign grain can be imported and sold at a lower price than grain can be produced on poor soils; and if there is no restriction placed on the importation of grain, experience will soon show whether it is more or less profitable to cultivate the deficiency of the home produce than to attempt to raise the whole that is wanted by cultivating poor soils. No country of large extent with a great population could obtain the whole supply of corn by foreign commerce; such an importation is not on record. But a manufacturing country which has up to a certain point produced all the food that is required for its population, will be stopped short in the development of its manufacturing power, if from any cause whatever it cannot obtain an increased supply of food. An increased supply of food and an increased supply of raw produce are the two essential conditions, without which the manufacturing industry of a country must ultimately be limited by its own power to produce. It may be that the population of such a country, if it is not suffered to import grain from foreign countries, it is a matter of indifference to all who consume the food where it comes from; and the agriculturist himself, as far as he is a consumer of food, is benefited with the rest of the community by the greater abundance of grain supplied by the grain-growing countries. The increased productive powers of the manufacturer. It is not necessary to determine how the increased supply of food will operate on wages or on profits, or on both: it is enough to show, that a time may come when there can be no increase of manufactures power, if the supply of food is limited to what the country produces; and that by an addition to the supply of food an additional power is given towards the production of those articles which monopolised their limit because the supply of food cannot be increased.

A country which has already produced from its best and its second-rate soils as much as these soils can produce in the actual state of agriculture, will begin to import grain from other countries, if there are no restrictions on importation. For capital will be more profitably employed in buying and importing foreign corn from countries where it is abundant than in raising it at great cost from inferior soils at home. It may be supposed that the quantity of grain imported will take manufactured articles in exchange, and if there are no restrictions on either side this must be the case; for the manufacturing country does not want the grain more than the agricultural country wants the manufactures. But it might be supposed that a certain limit of grain would be the general notion that the foreign trade would find it much cheaper to buy annually from grain-growing countries all the corn that is wanted to supply its deficient produce at home, than to attempt to supply the deficiency, or to add to the present stock of food, by cultivating very poor soils; and this, even if the grain-growing countries should refuse to take a single article of manufactures. The only way, indeed, of actually testing the truth of such a case as this is by experiment; but if commerce were free from all restraint, the importation of corn would become a steady trade, the amount of which would be regulated by the condition of agriculture in the importing country. If the importing country had brought all the better soils into cultivation, and the amount of forested land would not be indefinitely increased, the cost of production in the exporting country would be raised, and the limit of profitable corn-cultivation in the importing country would tend to increase importation. The limit of profitable corn-cultivation in the importing country, under its actual circumstances, would be determined by the cost of production; increase of population would tend to increase importation. The limit of profitable corn-cultivation in the importing country, under its actual circumstances, would be determined by the cost of production; increase of population would tend to increase importation. The limit of profitable corn-cultivation in the importing country, under its actual circumstances, would be determined by the cost of production; increase of population would tend to increase importation.
encourages the industry of the foreign country, supplies the wants of the importing country, and stimulates its industry by competition and the contrast of the home and the foreign article at the market. The variable profits and of bearing a rent, which, with the tax, could not be profitably cultivated or give a rent to the owner. The price at which the cultivator must sell his grain in order to continue to cultivate includes his profit and the owner's rent, and the price is paid by him who consumes the grain.

It remains to consider the effect of taxation on the exporting and importing countries. If both are free from taxation, or if the taxation is equal in both, or nearly equal, no nation will administer a tax which would be employed in some other way, as in pastureage or planting. Corn thus becomes dear; and agriculture is encouraged or protected, as it is termed, to the injury of the mass of the people, and to its own injury also, for experience shows that those branches of industry receive most improvements which are neither restrained nor encouraged, but are subjected to fair competition; in other words, industry to be most productive to a nation must have no other direction than what the hope of profit will make individuals give it. If foreign grain is not excluded, but admitted on paying certain duties, the evil is much less than in the case of absolute exclusion, provided the duties are not high, and provided they are uniform; for nothing except a uniform duty can regulate the foreign agriculture is not produced, or is produced peculiarly to the interest of the agriculturist. A uniform duty, as compared with absolute exclusion, is equivalent, so far as concerns the foreign trade, to an addition to the productive powers of the soil of the importing country. If trade is free, the farmer sends his grain to the market without raising the cost of production and the cost of transport do not raise the cost-price of such grain above that of the grain raised in the importing country. A miraculous addition to the productive powers of the soil of the importing country, or a sudden improvement in its agriculture, without any corresponding change in the exporting country, would at once lower the selling price of grain in the importing country, and diminish the supply from the exporting country. The effect is the same as if a tax of an amount equal to the cost of production were laid on foreign grain, for that duty will, in certain stages of the agriculture of both countries, just make the difference that prevents the foreign grain from being sold in the importing country at the same price as the native grain. In such case the foreign grain cannot enter the country till the price of the native grain has risen by an amount equal to such fixed duty; the mode in which this rise operates is considered in a subsequent part of this article. But there is this important difference, that a duty of two or three cents on ten or twelve bushels of corn cannot produce as decided a change as the fertility of the soil or a sudden improvement in agriculture and the case of a fixed duty, that in either of the two cases the country has an increased supply of grain, in the other it has not. In this case the limit of production is not perfectly ascertained, and the precise terms on which foreign and native corn shall enter into competition; and if the duty is moderate, and is considered necessary for the purposes of revenue, some people argue that a country is not ill administered in which such a duty is raised, though, if it is a manufacturing country rich in capital, such a necessary tax is an obstacle to the full development of its manufacturing powers.

If the duty is variable the trade cannot be steady, and consequently the price of corn may vary to every degree with very wide limits, an assertion which is not a conjecture, but a fact ascertained by experience. [Corn Trade, P.C.] If there is a duty, either variable or fixed, it gives to poor soils a value which they would not have if the trade in corn were free; for the price of corn on such soils is cultivated, and the price of food is regulated by the cost of producing food on the poor lands, and food is consequently dear. The cost of producing food on the rich lands is less; either owing to their abundance in fertility, or that less power and care are required, or owing to both causes. This superiority of rich lands over poor lands gives to them an increased value either as objects of sale or objects of hire; the selling price of such lands is raised, and the letting price is raised by a duty on corn; and their landlords also acquire a value that they have not otherwise have.

In a rich country it matters little if a capitalist who wishes to have land gives for it more than its value; such must be the case if the corn is dear; and if it is raised, the rent is likely to become a constant rent, and the desire and the power to purchase are constantly increasing. But the effect of a tax on foreign grain in a manufacturing country, when all the best soils are under cultivation, is directly to increase the value of land, and to add to the income of the landlord by making land capable of yielding a more valuable rent. Such a tax would be an obstacle to the culture of crops which would be less, the tax, could not be profitably cultivated or give a rent to the owner. The price at which the cultivator must sell his grain in order to continue to cultivate includes his profit and the owner's rent, and the price is paid by him who consumes the grain.

The whole mass of articles in the merchant's hands, foreign or native, must be at the same time raised, as in a country exporting, as well as a country importing. Any tax which the State may have raised, directly or indirectly, on the native produce, raises its price;
and the tax which it imposes on the imported article raises the price of that article and also the price of the native product. The average price, therefore, at which the merchant can furnish the articles of foreign land to domestic produce is raised, and the consumer must pay this price. The State derives no benefit from the tax or duty on the imported article beyond the bare amount of the tax; it may even be injured in other ways by the tax which the consumer is thus made to pay, for he may be made to pay more than the cost of the article, if cheaper than it is in any other country. The means of purchasing other things and paying other taxes are so far diminished. The effect on the producer of the domestic article, which comes into the market in competition with the foreign article, may be to lower the price, but it is not the same thing as having the foreign article being introduced and sold to any considerable amount while there is a domestic article, shows either that the foreign article is wanted to supply the deficiency of the home production, or that it is preferred to it. In either case the producer of the domestic article is injured. All consumption may be, but it is at least we pay if there were no duty on the imported article. The duty, therefore, gives something to the native producer, which he would not be able to get if there were no duty. This explanation applies to all articles of native produce which are not subject to an excise duty, if there are any such, and at least it applies to grain. Now the additional price which the producer of grain is enabled to get because there is an import duty on foreign grain does not ultimately go into his pocket; it goes into the land, which pays the occupier or another; for there is a competition among farmers for land to occupy, and they will offer rent up to that amount which will leave them the usual rate of profit, or even less, if they cannot cultivate their own land as equally as they do under the advantage of the tax; for he can either profitably farm his land when there is no duty on imported grain, or the duty on imported grain enables him to cultivate land which otherwise he could not cultivate, because the duty raises the price. The State raises a tax on the imported corn, which the consumer pays; and this tax enables the native producer of grain to demand of the consumer another sum of money, which is in the same or the same as the tax. All duties, therefore, paid are added into a country's products of that country, and are not subject to an internal duty, are of the class called protective duties, whatever their amount may be. It is not the object of this article to discuss how far such protection may be equitably given to any class of producers or proprietors in a highly-taxed country. It is sufficient to show that all persons as consumers are injured by the tax, and that the only persons who receive any benefit from it are the owners of land. If the land is not so highly taxed, and in which there is no duty, imported grain as in other countries, the injustice of such a duty is the more flagrant. [Land-Tax, P. C. and P. C. S.]

There is another mode of viewing the operation of a fixed duty upon corn (Economist Newspaper, Dec. 5, 1848). It is urged by the advocates of a protective duty, that such a duty would maintain that the rich man who has no need of the corn that is raised in the importing country, until the price of corn in that country has risen high enough to cover the price of his corn. This argument is fallacious. The raising of the price of corn in the consuming country would have the effect of raising the cost of transportation, and the fixed duty also. It is further maintained, that the price of all the corn in the importing country must be so raised before foreign corn will come in; and consequently, that in any season when there is a deficiency of corn in the importing country, it is not the duty on the foreign grain imported that must be paid by the consumer, but he will have to pay an amount equal to the fixed duty on all the corn that is raised in the importing country for the consumption of that year. But if the consumption is 20,000,000 quarters, and the deficiency is 2,000,000 quarters, a fixed duty of 5s. per quarter on the 2,000,000 quarters will cause a rise of 5s. in the quarter on the 18,000,000 quarters also. Accordingly the State will get the duty on the 2,000,000 quarters, which the consumer will pay, and some body else will get the 5s. per quarter on the 18,000,000, which the consumer also will have to pay. The truth of this proposition in its full extent may be questioned. The amount of the duty per quarter will be more than the duty on the 2,000,000 quarters, but perhaps somewhat less than the 5s. per quarter on the remaining 18,000,000 quarters. For something must be allowed for the fact that all the 18,000,000 are not in the market for sale at the same time. For instance, some 2,000,000 quarters of imported corn would be sold when the market price had risen to (say) 47s. the quarter; and an advance of shilling or two in the price would induce other holders to sell their corn; but all holders might not do so. The market price might then turn, and others would dispose of their ware-housed grain while the price was falling. The home market might then become depressed for a considerable period and during this period it might be so low as to render it unprofitable to import foreign corn, even if the duty were only two or three shillings. In this case the consumers would not be able to get any corn at all, and would have paid no tax, as the price of the foreign corn would have been free. Something also must be allowed for the disposition of merchants to speculate; and both they and the producers are liable to be acted upon by the apprehension of a future scarcity. The fact is that 6s. is merely the price of the foreign article, and prices are depressed beyond all reasonable calculation. We should be disposed, therefore, to qualify the assertion of the Economists by the conclusion that, in the importing country, with a fixed duty of 5s., the average price of corn in the importing country may be raised to a quarter higher than it would have been if the trade had been free; and perhaps this is all which the writer intended strictly to contend for. It may perchance turn out that the consumer will have to pay more than 5s. per quarter on the 18,000,000 quarters, or on some part of it; but it seems hardly safe to assert that he will have to pay exactly 5s., neither less nor more.

A chimerical difficulty is sometimes raised of this kind:—If a country does not produce all the grain that it requires, or if it is dependent for any considerable amount on foreign trade, it may suffer from scarcity in some seasons, and in time of war might be in danger of famine. As to the scarcity, every country is determined to be independent of foreign supplies, unless there is a regular trade in corn, that is, a trade into which a man can enter as he would into any other well regulated trade. If a scarcity should ever happen in the importing country, it will be remedied by the stoves of grain on hand that are supplied by a regular trade. The trade, unsteady and uncertain, the scarcity may be supplied or it may not: but it must be supplied at a higher cost, and sometimes it may be difficult to get a supply at all. Rome, both in peace and war, has been determined to be independent of foreign grain, but the supply was uncertain, for it was not all furnished in the way of regular trade, but sometimes called for as a forced contribution, sometimes accepted as a gift, and it was often purchased by the State, for the purpose of distribution among the poor, either grain or at a low price. All Italy imported grain largely under the early emperors. The scarcity with which Rome was sometimes threatened was not owing to the grain coming from foreign parts, but to the fact that there was no regular trade into which persons could venture by command of a body of persons able to pay for it. If a government shall regulate or attempt to regulate the foreign trade by scales of duties varying according to any law that the wisdom of a legislature may select, the result will be the same, great evil will be caused in consequence of the doctrine that every duty cannot be indubitably determined, and the difference whether the State imports directly or regulates the importation of its supplies by a capricious rule. The direct importation of the State, if we were well managed, would obviously be the most advantageous. What is here referred to the system applies only to the importation of foreign grain into the city of Rome. The necessity which existed for the importation is a question that can only be discussed with the question of cultivation in ancient Italy, and the gratuitous distribution of grain at Rome. De la Malle has some valuable remarks on this subject (Economiste Politique des Romains); but we do not assent to all his conclusions.

The fear that war might shut out the supplies of grain which a country might be import from abroad, that it cannot enter into the minds of those who view the question without prejudice. War does not and cannot destroy all trade; it may impede it and render it difficult, but trade has existed in all wars. The supposition that a rich manufacturing country cannot under any circumstances buy corn out of its superfluity, is a proposition which should be proved, not conjectured. It belongs to those who maintain this proposition to give reasons why it is not to be expected.

For some remarks in this article the writer is indebted to Gailh, Dictionnaire d‘Economie Politique, art. Agriculture.

AGRICULTURE, STATISTICS OF. In several countries of Europe there is a department of government organized either for collecting the statistics of agriculture or superintending institutions which have immediate relation to that branch.
of industry. In France these duties devolve upon a department of the Ministry of Commerce and Agriculture. The management of the royal flocks, veterinary schools, and the royal stews; the distribution of premiums in agriculture; the organized research, and the development of the technical side of agriculture, are comprised in the duties of this ministerial department. The councils-general of agriculture, &c., in each department of France collect the agricultural statistics from each commune; and the quantity of land sown with each description of produce, the kind and the margin of stock for the whole of the kingdom, are accurately known and published by the Minister of Commerce and Agriculture.

In Belgium these facts are ascertained periodically, but not every year. One hundred and one agricultural departments, forming a part of the decennial census, an attempt is made to ascertain the number of each description of live stock, including poultry; the produce of cereal grains, and of various crops; the quantity of dairy, orchard, and garden produce, &c., in each State. There are twenty-nine heads of this branch of inquiry. The only countries in Europe which do not possess statistical accounts of their agriculture founded on official documents are England and the Netherlands. In England the quantities of corn and grain sold in nearly three hundred market-towns, the quantities imported and exported, and the quantities shipped coastways, are accurately known, but no steps are taken by any department of the government to ascertain the quantities produced. On the same principle that a census of the population of each State can be made, the distribution of the produce can be ascertained from the total output of the different kinds of agricultural produce, and the productive resources. The absence of official information is supplied by estimates of a conjectural character, founded at best only on local and partial observations. In France it is possible to ascertain that the average produce of wheat for the whole kingdom is deficient. In the circumstances of our agriculture it is known that the maximum produce of wheat per acre is about forty bushels, and that the minimum is about twenty bushels. The usual conjecture is that the average produce of the kingdom in years of fair crops is about thirty-eight bushels, but the total superfluities sown with wheat or any other grain, and the total quantity of the produce, are matters simply of conjecture. The only statement the public or even the government are in possession of in respect to the quantities of cultivated and uncultivated, and of land incapable of producing grain or hay, in Great Britain, rests upon the authority of private inquiry made by one person, Mr. Coulson, a civil engineer and surveyor, who gave the details to the parliamentary committee on emigration in 1837, now seventeen years ago. As there is an account published weekly in the 'London Gazette' of the quantity of each description of grain sold in nearly three hundred market-towns in England, with the average prices, and the quantity of foreign corn and grain imported, the means are introduced within the hands of the community the important elements of calculation in reference to the supply of food, if they could also learn after each harvest what had been the breadth of land made up of all wholesome or grain-bearing land, the amount of produce harvested. The result could not fail to be felt in greater steadiness of price, which is particularly desirable for the interests of the tenant farmer, and also highly advantageous to the public. For example, the harvest of 1837 was so great a degree, that before the produce of 1838 was secured the great superabundance of the two preceding harvests was all consumed, and the stock of grain was more nearly exhausted than it was ever known to have been before. In the beginning of the year, 1838, there had been a check in consumption, which, as regards wheat, had been going on with unwonted profusion, but in August, September, and October, 1837, the markets fell from 60d. 1d. to 51s. per quarter, and it was not until the middle of the following May that the average was again as high as it had been just before the harvest of 1837. By the third week in August, 1838, the average had risen to upwards of 73s., and wheat was admissible at the lowest rate of duty. The buyers consequently resorted to all that was conveniently sold with solid bodies, or there was an increased importation of foreign grain, resisted by a wild spirit of speculation, which subsequently was productive of great loss to importers, rose enormously. It is contended that these losses and the fluctuation of prices would not have occurred if the produce of the harvest of 1837 had been accurately known and published before the harvest of 1838. The preparatory statistics of Agriculture, by G. R. Porter, Esq., of the Board of Trade, the probable operation which statistical facts officially collected would have upon agricultural improvement are thus reported to by Mr. Porter. It has been stated that if all England were as cultivated as the counties of Northumberland and Lincoln, it would produce more than double the quantity that is now obtained. If the cultivator of land where agricultural knowledge is the least advanced, could be brought to know, upon evidence that could not admit of contradiction, that the produce of the single grain, procured, from land of fertility not superior to his own, larger and more profitable crops than he is in the habit of raising, is it likely that he would be contented with his inferiority? In 1856 the late Lord Sydenham, while president of the Board of Trade, published the results of an inquiry that might result from a more extended attempt, caused circular letters containing fifty-two simple but comprehensive queries relating to agriculture to be sent to each clergyman in the parishes of the United Kingdom. Out of this number only 27, or about one in five, replied, and further inquiry was abandoned. The tithe commissioners make returns of the crops in all parishes, but they do not do so simultaneously. There is however no insuperable difficulty in collecting the national statistics of agriculture, when ever government thinks fit to undertake such a duty. On the 18th of April, 1844, on a motion in the House of Commons for an address to the queen praying for the establishment of some method of collecting agricultural statistics, the vice-president of the Board of Trade, on the part of the government, concurred in the object of the motion, but from various causes he declined at that time giving the motion his support. The yearly expense of the inquiry would be from 20,000l. to 40,000l., which would not be an excessive sum, if the appropriate machinery will be in operation. In this way the government advance the interests of agriculture and of the public at the same time. In a country like England, which abounds with men of rank, wealth, and intelligence, who engage in science at their leisure, the government is quite unnecessary for the government to assume the superintendence of matters which relate to practical agriculture; but this may be done with propriety in other countries, which are placed in different circumstances.

AIR BEDS AND CUSHIONS. The mechanical application of common air, in respect to its pressure or elasticity, has been greatly extended within the last few years. The pressure of fourteen or fifteen pounds on the square inch, which is the weight of the air at the surface of the earth, is known to be the maximum, and the air at the surface of the earth, is a mechanical agent which, under certain arrangements, becomes a substitute for powers of a very different kind.

Provided a mass of air can be confined within a given receptacle, and that receptacle be of an elastic or yielding character, the air assumes many of the qualities of a soft stuffing or padding, when its quantity is small compared with the size of its envelope; but when the quantity is so great as can be enclosed in a space as large as the human body, the shape of the air is in fact nearly equivalent to a solid body. So long as the means were wanting for conveniently making air-tight cloth vessels, this principle was slumberly applied; but the use of the envelope, as a new substance and new animal, has, from the first, developed many ingenious contrivances for this object.

Almost any textile fabric may be rendered impervious both to air and water by the use of some one or more of the coagulating compositions [Water-proof Cloth and Leather, F. C.]; and when a bag has been made of such material, rendered also air-tight by somewhat similar means at the seams, air may be passed into it as a substitute for more solid materials. In practice there are some very neat arrangements adopted in making air-engines or air-cushions. The air is made to form a bag of air-tight cloth, perfectly enclosed at every part except one corner, where is inserted a small tube and stop-cock, capable of admitting or preventing communication from the interior to the exterior. The cock being opened, and the tube applied to the mouth, air is blown into the cushion, until it expands to the desired degree of fullness; the cock is then closed, and the air remains imprisoned. In this state the cushion is of a more equable kind than any one can find by the hand, and if the air be not allowed to escape, it will retain its efficacy for a long time. When not in use, such a cushion can have the air expressed from it, and may then be folded up into a small space.

It is obvious that seats, cushions, pillows, and bags of various kinds, having a similar object in view in respect to softness, fullness, and elasticity, may be made by similar means. When the quantity of air included in an envelope is greatly increased, it may be made the means of producing actual pressure in a more equable way than by any solid bodies. Thus, an air-tight bag was invented a few years ago.
AIR

which many persons had an opportunity at the time of seeing a specimen at the Polytechnic Institution. The object of this arrangement is to form a wrapper to an arm or limb under surgical treatment. There is a bandage with straps, capable of being conveniently tied round the arm; and when so tied, air is breathed into an air-tight envelope to the bandage, through a small tube provided with a pipe: by increasing or lessening the quantity of air impelled, the pressure of the bandage is readily regulated. This arrangement is said to have a similarity to the apparatus of the people of the ancient Tartars, and may be even painfully close, and it will be capable of being regulated in different parts.

About four years ago Mr. Walton took out a patent for certain modifications of the mode of using air-bags for beds and similar purposes. The plan seems as if it must necessarily be a costly one, and is thus described,—There are first made a number of globular air-vessels of India-rubber, in one of two modes. In the first mode, a metallic receiver is one is capable of being moved up and down by its connection with a stop-cock, at the upper part of this receiver there is a pipe furnished with a stop-cock; a jointed lever, countersunk on the under side, is brought down upon the pipe, a small aperture being made through the lever opposite the centre of the pipe. India-rubber bottles are cut in half and soaked in water at 100° Fahr., and afterwards in cold to facilitate their separation into laminae; the thin sheets thus obtained are placed over the pipe and held down upon it by the lever. Upon their way down, the air passes through the cock, the air-tube up through the aperture in the lever, expanding it into a ball; in other words, the force of the compressed air both makes the ball and fills it by the same action. When brought up, the receiver sinks down, or rests against the required resistance, the ball is tied round with thread close to the lever, the superficial edges are cut off, and the joint secured with India-rubber cement. The second mode of making and filling the air-balls consists in the use of a pair of hemispherical cups hinged together, and both connected by a tube with a metal receiver furnished with a stop-cock. A piece of thin sheet India-rubber is stretched over each hemispherical cup; and the air being then extracted from within, the external air forcing the membrane to conform to the interior of the cup. The two cups of India-rubber are then joined together, forming a ball. The balls, made and filled by either of these methods, are connected together, either externally, or by being enclosed within an external covering, forming a sheet of balls. Many such sheets may be laid upon each other, enclosed in an outer case, to form a bed or mattress of any thickness. The object of this complicated plan is stated to be, the limitation of an accidental injury or rupture to one small portion.

AIR-VESSELS are the parts constituting a piece of machinery invented by Mr. Cubit to serve the purpose of a fly in regulating the motion of a wheel which, as a prison discipline, is turned by men.

A two-cylinder was employed, each of which is cylindrical, and consists, like a pair of bellows, of an upper and lower board, with sides of leather: the vessel has only one aperture, and the lower board is made fast to the floor, while the upper one is capable of being moved up and down by its connection with a crank which turns on the axle of the wheel. A sliding plate having holes pierced in it is capable, by wheel-work, of moving before the aperture, so as to diminish the latter to any required extent, and is connected with the governing balls of the machinery.

Thus, when the velocity becomes too great, the divergence of the balls causes the sliding-plate to pass more or less over the aperture and contract its dimensions; by which means lessened air is expelled, and the resistance is created which diminishes the speed. Or, in the event of the velocity becoming too small, the balls descend, and the sliding-plate is drawn off from the aperture, by which means the air enters and issues more freely, and thus the resistance to the motion of the machine is diminished. (Transactions of the Society of Arts for 1827.)

AN apparatus of the same or a like kind might be employed for other purposes: for example, in lowering heavy goods from a height from the upper part of a warehouse; and an ingenious machine, in which the resistance was produced by the passage of water or oil through an orifice, is or was in use at some of the warehouses belonging to the East India Company.

It consisted of a cast-iron box immovably attached to the ground, or floor, and a bellows for furnishing two hollow cylinders, in vertical positions and of equal heights, separated from each other by a portion of the material. The two cylinders were capable of holding about a gallon of fluid, and they communicated with each other by openings left near the top and bottom of the material between them. In the larger cylinder was a solid piston which ascended and descended in consequence of its connection with a crank on the axle of the wheel by which, in general, goods were raised up to the place. In the middle of the smaller one was a circular plate capable of being turned about an axis in the direction of the wood, and thus to have a specific or variable resistance to the motion of the cylinder.

In use, the two cylinders were nearly filled with water or oil and the piston being and filling alternately as the goods in descending turned, by the cranio-cope, the axle of the wheel, the resistance created by the passage of the fluid through the communications between the two cylinders and through the opening at the circular plate, prevented them from descending and the amount of the accidents to which a simple brace is liable was avoided.

AIX EN PROVENCE. In the fresh-water deposits of this locality many fossil insects have been detected. (Murc.)

AIZANI or AZANI, Antiquities of, (Aizavoi, 'Arzavel) according to its modern name, Tchaffer-Hissar, a city of Asia Minor, in the antient province of Phrygia, about nine hours journey from kutahia. It is mentioned by Strabo (v. 1827), and there is a view of the place given by a name of Azani; other authorities write the name Aizani (Stephan. Byzant. v. 'Arzavel). Nothing is known of its history, and its existence has been almost forgotten until recently. When Lord Elgin, in 1815, opened the ruins of 'Samothrace, and by his means could have an opportunity to examine the numerous remains of extensive edifices have given it archeological interest in the history of architecture. Lord St. Aasoph was the first who communicated any intelligence respecting these ruins (1825), which were visited about the same time by Count de Jussieu, and by Major Keppel; but it is to Charles Tectier, the architect, who, after completing his studies in Italy, was sent out by the French government to Asia Minor, about 1834, that we owe extensive views of the ruins. He finds the name of the site to be Aizani, which is believed to have formed an elevated platform or terrace cut out of the hill and perfectly regular in its plan, which is a parallelogram and nearly a square, its measurements being 592 feet (Eng.) on its north and south sides, and 460 on its east and west. The roads or remains of edifices which it is conjectured that the platform of the temple formed a peribolus or court to the temple, enclosed on three of its sides, while the east one (corresponding with the entrance end of the temple) was left open, and on that side the terrace was decorated architecturally throughout its entire extent by a series of twenty-two arches with pilasters between them, i.e., eleven on each side of the central flight of steps (100 feet wide), forming the ascent to the upper level. Thus the terrace here formed a magnificent substructure that, together with the temple, must have produced an unusually striking and imposing effect. The temple itself stands exactly in the centre of the peribolus or platform, consequently exactly in the axis of the temple. On the east side are inscriptions found among the ruins to have been dedicated to Jupiter of Aizani, is now more than half destroyed, little more remaining than the columns of the north and west sides and the corresponding portions of the cela; yet what is left affords sufficient data for determining the accuracy of the particulars in regard to its plan and the peculiar character of its order. Referring to the article Temple in the 'Penny Cyclopaedia' for an explanation of the respective terms, we may give a brief description of it thus: an octagonal cela, with twelve dorodipteral with fifteen columns on its flanks, therefore exactly corresponding with the cut which is there given (p. 182) as an example of a pseudodipteral plan. Its general dimensions do not appear to be exact, but it was near 53 feet by 63 feet, the broad side on the north, which it is raised, 121 by 72, and therefore of more probable dimensions of the cela, it is much smaller than some of the structures noticed in the 'Table' of them in the 'Penny Cyclopaedia,' nevertheless

ALA

considerably larger than some of the most celebrated of them,—for instance, the Marathon Carreé at Niammes, which is only 38 by 77 feet. The whole is constructed of white marble, and the columns, 31 feet high, are each of them wrought out of a single block; but what gives such interest to this monument is that it affords a very remarkable example of the Attic Ionic order. The rows of the flutes of these are so very diminutive that they could hardly have been distinguishable at that height, and therefore were probably intended only to produce the effect of an enriched cillion or necking to the capital with the fluting separated from it. Furthermore, the columns, both for its proportions and decorations: the architrave, which is divided into three façades with carved bead mouldings, is considerably deeper than the frieze, which excess is caused by the unusual breadth of its coping, consisting of a large ovo and cavetto above it, both enriched. The frieze is still more remarkable—e'en unique in its design, which is such as to render it most difficult to describe: large upright acanthus-leaves placed singly at intervals after the manner of triglyphs, are interspersed with two panels within the limits of each of two scroll-like volutes meeting each other in front like those at the angle of a Corinthian capital, to which they bear a very strong resemblance; therefore taken with the acanthus-leaves they were evidently intended to produce a Corinthian-like effect. The corona again differs both from Greek and Asiatic-Greek examples of the order, inasmuch as, in addition to the dentils of the latter, it has small modillons: this corona is narrow; the gymnasion above it, on the contrary, is very deep, and, or apertures in the pavement of the colonades next the walls of the cells, and the steps leading to it were within the peristyle. Several columns now lying on the ground within the peristyle indicate that that enclosure must have been adorned with them, since they evidently do not belong to the temple itself, being not much above half the size of the others, and besides the lower part of their flutings are cabled.

The most notable among the other monuments discovered at Alaini are a theatre, stadium, and gymnasion: the first of these, which is in better preservation than almost any other ancient structure of its kind, is 185 feet in its greatest diameter, and the spectatory had sixteen rows of marble seats, but the theatre itself is divided into the usual three parts: the podium however of that tier, or the wall of the precincts separating it from the lower one [Theatre, P. C., p. 294], is for the greater part remaining, and shows one peculiarity, namely, mutual division at intervals in pairs, of which there were altogether 24. The orchestra forms more than a semicircle with a radius of 66 feet. The scene was decorated with six pairs of coupled Ionic columns, but these have fallen down, and are lying with a mass of other ruins and fragments in the midst of the foundations.

The stadium, which is a little to the south-east of the theatre, measures 725 feet in its extreme length and 152 in its extreme breadth. There were two pavilions or logia, one belonging to the dependence of the king of the Alains, the other to the company of runners; and ten rows of seats along each side, capable of accommodating between 12,000 and 13,000 persons.

Of the gymnasion, or what is supposed to have been such, which is situated to the south of the peribolos of the great temple, there are few traces remaining; and it had a colonnade extending upwards of 200 feet, whose pillars are all of white marble and of a single piece. To the north-west of the temple are also some ruins of what is supposed to have been a basilica. The river Rhynemus, which passed through the city, was crossed by two bridges of white marble, each consisting of five semi-circular arches. Both are remaining, as are also the parapets of the quays along the river, which, like the bridges, are constructed of white marble and ornamented with sculptures. There are besides many tombs, whose doors and portals (represented in Texier's work) afford valuable architectural hints and studies.

Alani ('Aladros') is the collective name of different nomadic nations that lived in the countries north of the Euxine and the Caspian, and may be divided into European and Asiatic Alani. They became early known to the Romans, if the Alani mentioned by Strabo (c. 75, xxvi. 2) are the same as those of whom we speak, and not the Alaini, who lived in the southern quarter of the present country of Daghistan and in Shirwan, and are mentioned by Strabo (p. 495, Cai.), Prokopius, and many other ancient writers. The Alani of the time of Ammianus Marcellinus (xxxi. 2) says that the Alani were the same as the antient Massagetae, which is probable if we take the name in its collective meaning, for the same author says (xxii. 19) that the Alani lived north of the Massootia, a country of which the Massagetae, in early times, have even remained names. The name appears to have originally belonged to a Caubian tribe which lived between the chief range of the Caucasus and the Forte Caspiae, now the Iron Gate, near Derbend, and as far north as the great steppe between the Araxes and the Volga; and it is probably this tribe which subdued the neighbouring nations, and to which we must refer the words of Ammianus Marcellinus (xxxi. 2), who gives the best description of the Alani; he says that the nobles among them were about five hundred, and that they were a handsome people. The Alani are of small stature, of a delicate and fair complexion, and of a singularly light, but they liked warfare above all other occupations, and made frequent incursions into the Roman provinces. Their arms were excellent, and the arms of the men were light, and well suited for a predatory mode of warfare. The Romans fought many battles with them, but not always to their advantage. The Emperor Gratian was defeated by the near Philipopolis a.D. 245; and they took a decisive part in the victory which they the Alani obtained in a.D. 376, near Adrianople, over the Emperor Valens, who was killed in or after the battle. (Ann. Marcell. xxiii. 15.) In a.D. 406 and 407 the Alani became still more conspicuous by invading Gaul with the Vandals, Suevi, Burgundians, and other barbarians. After having lived some years in that country they joined the West Goths and Vandals for the purpose of invading Spain, which soon yielded to their advance (near 411). The Alani were then settled in Lusitania and the province of Cartagena, and lived for some time under their kings till they quarrelled with the West Goths, whose king, Wallia, defeated them in a.d. 440 in a pitched battle, where the Alanian king Atax lost his life. Upon this the Alani joined the Vandals, and shared their fate in Spain as well as in Africa. After a.D. 440 they ceased to be an independent nation. The later part of their history can only be traced in the dry and short chronicles of Prosper, Gregory the Great, and Isidore of Seville. At the time of the Spanish expedition in a.D. 411, but remained in Gaul under their king Goar. In a.D. 440 Atius, the Roman governor of Gaul, allotted them settlements in the environs of Valence, with a view of making them serve as a barrier against the Franks. Their king then became a suzerain of the Emperor Theodosius, and was invested with the title of Atius with the command of Orleans, which Attila was besieging in a.D. 451; and it appears that he was bribed by the Hunnic king, to whom he would have surrendered the town if he had not been closely watched by the Romans and the West Goths, who trusted him so little, that in the great battle on the Campi Catalanei they put the Alani between their most faithful troops, and thus compelled them to fight. The second expedition of Attila into Gaul, which seems to be an other fact, although it has not been generally admitted by the author who mentions it, was undertaken under the pretext of subduing those Alani of Valence. Gregorius Turonensis states (Hist. Franc. ii. 7) that they were deprived of their country, the king of the Alani, with the title of Atius, and that the name of the Alani occurs in all the later historians, among whom besides those quoted above, Zosimus, Procopius (in his 'Bellum Gothicum,' as well as in the 'Bellum Vandalicum'), and Fracus, are the best sources. All the passages of these anonymous writers are, according to the nation are included in Stritter, 'Memoriae Populi.'

For many centuries after the destruction of the Alani in Spain and Gaul their name occurs in the later Byzantine writers, and we have many modern maps in which a whole line, more or less, is drawn down as inhabiting the tract between Derbend and the Kuma. Ethelwold, a most competent writer on these matters, shows that this arises from a mistake, the Byzantines having confounded the Alani with the Albani, a Turkish tribe, with which the Greek emperors were engaged in perpetual war.
The Alani were undoubtedly a Cassianian nation, and as the social state of the Caucasian tribes seems to be nearly the same as it was fourteen hundred years ago, a nearer acquaintance with these people will enable the student to form a pretty correct idea of the state of civilization of many of the barbarous nations of the Roman empire. The feudal system is a very old institution in Caucasus.

(Aichwald, Alte Geographie des Kaspischen Meeres; Mascou, Hist. der Antient Germans, translated by Lediard; Rakkah.)

ALARIC II. (ALARIC/CUS), king of the West Goths, succeeded his father Eudes in A.D. 484. Gothia, the then name of the West Gothic kingdom, had been considerably enlarged by Eudes, and extended over Hispania Terraco- nomica, Pannonia, the Rhine and Gaul itself. From the Rhine, by which rivers it was separated from the kingdoms of the Franks, the Burgundians, and the East Goths, who were masters of the province. If we can trust Isidorus, Alaric had spent his youth in idleness and luxury, though the truth seems to be that, preferring a peaceful reign to war, which in the eyes of the Goths was the only occupation worthy of kings, he incurred that reproach because he was not fond of bloodshed. He was an Arian, as most of his countrymen were; he was a very able man, from the acts of the Council of Agde, which was held in A.D. 506, and by which many privileges were granted to the orthodox Catholics. His toleration was the cause of his ruin. After his death his successor, the last of the Franks in Gaul, coveted the fine countries west of the Loire; and there being still many Catholics in Gothia who were dissatisfied with his king because he was merely tolerant towards the Catholics, and did not adopt the Catholic religion, the kingdom was divided. By the Treaty of 607, the East Gothic king, Theodoric the Great, whose daughter Theudighota was the wife of Alaric, foresaw the war, and tried to prevent it by conciliatory means: the letters which he wrote to that effect to the kings of the Franks, the West Goths, and the Burgundians, are preserved by Cassiodorus; but his endeavours were in vain, and the war broke out in A.D. 507.

For twenty-three years the Goths had had no war of consequence (for that they should have had no feuds with their neighbours the Franks and Sueves, and yet live together in peace, their habits of life were rather relaxed; while the Franks sincerely knew what peace was, and improved their discipline in continual contests with their neighbours. When the West Goths and Franks came to settle their difference in a pitched battle near Vougle, in the environs of Poitiers, the result proved fatal to king Alaric, whose army was entirely defeated. Alaric fled, but was overtaken and killed. Gregorius Turonensis mentions his death in a few words, too vague to be exactly translated; and finds that he was a rival with his own hand, as several modern writers say. The Goths made a halt at Narbonne, and, unfortunately for them, quarrelled among themselves about the choice of a new king. One of the elders, Gesallos, who was the eldest of the bastard son of Alaric; and another Amalasun, the lawful son of Alaric and Theudighota. This prince being too young to rule, the regency over the West Gothic kingdom was intrusted to his grandfather, the East Gothic king Theodoric, who drove Gesallos out, and compelled the Franks to restore their conquests. A proof that Alaric was peaceable because he appreciated the blessings of peace, and that he was able to consolidate that peace by a regular system of legislation, is the code called The Germanic Alaric (C. 0. 3).

(Cassiodorus, Variorum, 1. 3. 1., rec.; Gregorius Turonensis, ll. 36; Procopius, De Bell. Goth. ll. 12; Jornandes, De Reb. Goth. p. 129, ed. Lendenborg; Isidorus, Chron. Goth. ad an. cre 522; Mascou, Hist. of the Antient Germans, translated by Lediard; Aeschbach, Geschichte der West- gothen.)

ALBA, the province of, an administrative division of the Sardinian States, is bounded on the east by Acqui and Alessandria, on the south and west by Cuneo and Mondovi. The country is hilly, and it is intersected from south to north by the Tanaro, an affluent of the Po. The products are wine, corn, pulse, fruit, and silk. Truffles are dug up in many places, and are an article of export. A considerable number of vineyards are cultivated in this province.

The area of the province of Alba is about 800 square miles, and the population is 103,700 inhabitants. It is divided into eleven mandamenti or districts, and seventy-seven communes.

The head town, Alba, a bishop's see, is situated in a fertile plain near the banks of the Tanaro, and contains 8000 inha-

Alba, the cathedral, built in the fifteenth century, and several other churches; an hospital, a royal college, a clerical seminary, a literary and philosophic academy, and several private collections of antient medals and other antiquities which have been found in the neighbourhood. Alba was a town of the Statielli, and it is said to have been restored by Pompeius Strabo, the father of Pompeius Magnus; in consequence of which it was called Alba Pompeia. The Emperor Pertinax was born at Villa Marsia near Alba, where there is still an ancient temple of Jupiter. It is said that the celebrated rescript of Pertinax, which has been found in a farm called Le Martineng, the owner of which has published an interesting account of the same: 'Della Villa di Marta, Casa, e Leri dell' Imperatore P. Elvio Pertinaco ne' Celto-Liguri-Tanaro; Illustrazione del Conte Ant. A. L. Pertinax, Firenze, 1818.' A sepulchral altar of marble, with a frieze of elegant workmanship, was found in the bed of the Tanaro in 1779, bearing the names of Calvis Cornelius Germans, sedilis, mastor, duuriv, and aceddios, and of his wife Marcella. This monument has been illustrated by the antiquarian Baron Vermazzia: 'Germani et Marcellae Ars Sepulcralis Commentario Illustrata.' The monument is deposited in the court of the town-house. In the middle ages Alba was one of the principal towns of the marquisate, and was annexed to the dominions of the house of Savoy by the treaty of Cherasco in 1631. The learned Vida was many years bishop of Alba.

The other towns of the province are: 1. Brk or Braida, a considerable place, of 10,000 inhabitants, in a district abounding with corn, wheat, fruit, cattle, and silk. Brk is not far from Pollena, built on the site of the antient Polletia, where Stilicho defeated the Goths, A.D. 403, and for a time saved Italy from the barbarians. B. Brk and Trakes, 8 mile distant; 2. Canale, with about 4000, and other smaller places. (Casalis, Dizionario Geografico, Statistico, Commerciale, degli Stati di S. M. il Re di Sardegna; Denina, Quadro della Anti- Italia; Calendario Sordi; Serristori, Statistica dell'Italia.)

ALBATEGNIUS (Astronomer). D'Herbelot calls him Mohammed Ben Giber, but Mr. Gayngoes, who has given more particulars of him than any one else (in the Biog. Dict. de la Science de l'Annee 12), gives Jafir Ibn Senan Abd Abdullah. The term Albategnius is the Latinized form of El Batani, or Al Bateni, from Batin in Mesopotamia, where he was born. He lived in parts of the ninth and tenth centuries, beginning his astronomical observations in A.D. 977, and continuing them till his death in 999. He generally resided at Rakkah (Arcata) or at Bagdad. His writings comprise abridgments of Ptolemy and Archimedes, with comments; a work on astronomy, chronology, and geography; and another on astrologers. He is distinguished for his points of astronomy; an elementary treatise on astronomy; and one on astrology; with minor works. The treatise on the rising of the constellations (Lalande inverb., Delambre) was translated from Arabic by one Plato Tiburtinus, but badly (as he was the astronomer of Alhazen). This treatise, as first as 'Alfragan Rudimenta Astronomiae, et Albategnii Liber de Mota Stellarum ... cum Joh. de Regiomontiano Orto- introduc- toria ... Norimbergae, 1537, 4to.: next a 'Albategni de Scientia Stellarum Liber, cum aliquot Additionibus J. Re- giomontani ... editi Bernardinus Ugulotus, Bononie, 1645, 4to. Both editions leave out the tables which the book was written to explain, from which it is difficult to form a very accurate idea of the labours of Albategnius; but there is a very good treatise on the subject of the earth which he was the author of, and a very independent turn of thought: it is likely that he was among the first, if not the very first, to find out that the data used by Ptolemy required correction. He seems to have had no other guide; the Indian summaries are not found in his work, so that it is difficult to suppose that he derived any astronomy from that quarter.

He was the first who rejected the chords, and substituted sines in the place of them, or the sine, after the trigonometric improvement we are reserved to the fruits of this day, he was long since (and though without seeing the full extent of their utility) tangentia. He determined the obliquity of the ecliptic with the parallactic instrument as described by Ptolemy, in such manner as to take in the corrections of later times and his work gives 0°50' for the annual diminution of that element: our modern tables give it, at this time, 0°47'. His sines gave trigonometry, even in his own hands, quite a new appearance and a new power; and he had a much greater number of methods in spherical trigonometry than the Greeks. It is
most likely that he invented those himself, for he distinctly
intimates himself to be the first who abandoned the chorda;
the rules for finding the third side from two sides and the
included angle, and the angles from the sides, must be attrib-
uted himself and Ptolemy for the right-angled triangles. He
determined the length of the tropi-
cal year, making it only 2m. 26s. too short; a result much
more exact than that of Ptolemy. The same may be said of
his determinations of the precession and calculations of the
day of the solar apogee and of the excentricity of the earth's
orbit. Looking at his determinations of the two latter, and
seeing that he does not infer that they are changeable ele-
ments, we are left to conclude that he attributed the difference
between himself and Ptolemy, at least in part, to error of
calculation. Rather, as in the research of Albategnus that succeeding
astronomers were able to infer the variability in question, and as
the only reason for his not inferring it was his well-grounded
ward of confidence. Ptolemy's results, he has the merit of
the discovery.

Several writers have affirmed that he did
announce it; but incorrectly. The changes which he made in
the lunar theory of Ptolemy are slight; and in his planetary
theory he has very little success. For a fuller account of his
work, see Delambre, 'Hist. de l'Astron. Moyenne,' 10-32.

This learned and excellent historian, who rarely lets an author
go without stripping a few leaves from his crown, shows Albe-
tegnus to great advantage in comparison with Ptolemy as
an astronomer, though of course of less importance as a theorist;
and the subject of our article may fairly take
rank as the greatest of the Arabian school, which forms
the link between that of the Greeks and our own.

ALBENGA, the Province of, an administrative division of
division of the Kingdom of Sardinia; contains about 10,000
souls situated on the southern slope of the Maritime Alps, which
here become blended with the Apennines, and it stretches along the
coast of the Mediterranean for about 30 miles. Its
greatest breadth is about 15 miles. It is bounded on the north-east
by the province of Savona, on the south-west
by that of Onglia, and on the north by the province of Monferrato
in Piedmont. The country is intersected by objects
of the Maritime Alps which run to the coast, and form narrow
inlets with their terraced and orange-covered sides, giving
time to sea and rain. The only river that does not dry up in summer
is the Aroa, which rising in the province of Onglia on the
western slope of the high ridge on the opposite side of which the
Tanzaro has its sources, flows in a south-east direction through the
long valley of La Plave, receives a number of
mountain torrents, and afterwards entering the plain of
Albenga about four miles above its mouth assumes the name of
the Cenis, and then joins the sea to the west of
the town of Albenga. The whole town was
indeed built on an island about 800 square
miles. Formerly the river flowed to the eastward of
Albenga, where a Roman bridge is still seen of ten arches, the
pier of which are now buried in sand. In seasons of heavy
rain the water rises so high as to completely
 inundate the plain and the town of Albenga, until
the Castellane Somia, not long since Intendente or governor of the
province for the king of Sardinia, caused the river to be
embanked above the town, which was thus secured from the
flood. He also filled up with sea and the marche near the
coast, which in summer infected the atmosphere. The malaria
fevers have now almost entirely disappeared from the territory
of Albenga. The plain of Albenga, one of the few plains in the
Propesean territory, is dedicated for the harvest of
the wheat, being the region of the largest
fertility. The town of Albenga, the head town of the province, situated in
a plain about a mile from the sea-coast, is a bishop's see; it
has several churches, some lofty towers, a grammar-school, and
in him; with great admiration. The
province of Albingaunum was formed by the union of
Scipio and
the province of Albingaunum and was finally
subdivided by the Province L. Emilius Paulus,
ae. 161 (Livy, xi, 25-29). Albingaunum was the birthplace of
T. Julius Fuscus, who assumed for a time the imperial title
in the name of Pompey; not without good
Scipio, called Mucius, and were in the
Historia Augusto.) Several Roman inscriptions and other
remains are scattered about the town. In the middle ages,
Albenga governed itself as a municipal town under the
supre-
macy of Genoa. The other towns of the province are:
1. Aliso, a town on the coast, south-west of Albenga; it
has a collegiate church, a communal college, and 6300 inha-
bilants, mostly adm0ined, with great admiration. The
province of Albingaunum was formed by the union of
Scipio and

remains are scattered about the town. In the middle ages,
Elizabeth to the Virgin, in the imperial gallery of Florence; it contains however only the two saints, but beneath it is a predella in three compartments, illustrating in small figures the labours of Hercules; among which was the Last Judgment, for the cemetery of Santa Maria Nuova, which, says Vasari, many suppose to have been the entire work of Bartolomeo. Alber- tinitelli was so much distressed at losing the society of Bart- olomeo, and finding himself in a foreign land, that he had much difficulty in preventing him from following his example. Vasari says that he died about 1620, aged 46, the victim of his own debaucheries. He had some distinguished scholars; the best was Visto, who, according to Vasari, died in Hung- ary; others were: Giuliano Bugiardini; Franchisciano; and Innocenzo da Imola.

Alberinitelli painted in fresco in Florence, in Viterbo, and in Rome. Vasari mentions a very excellent portrait by him of the Florentine author, Manuzio, daughter of Roberto Orsini, the constable of Naples. A picture in the Louvre by him is inscribed:—"Maricocci De- bertinella Opus. Ano. Dom. M.D.VI."

In the chapter- house of the Carthusians at Florence, a crucifixion in fresco, with the story of the entrance of Charles V into Florence. (Vasari, "Vite de' Pittori," &c.)

ALCAMENES, (Alca'me'nês) a celebrated ancient sculptor, and a native of Athens. He was the pupil of Phidias, and lived therefore in the middle of the fifth century B.C., and later. Phidias, Alcamenes, and Polycletus were the three greatest sculptors of ancient Greece; Alcamenes survived Phidias some time, as he was still living in the 95th Olympiad, according to Pausanias, about 400 B.C., for, as many of his colonists statues of Mares, and Hercules, to commemo- rate the victory of Thrasylus over the thirty tyrants, which he dedicated in the temple of Hercules at Thebes: this victory took place in the second year of the 95th Olympiad, or 405 B.C.

Alcamenes was sculptor in marble and statuary in bronze; his most celebrated work was a Venus, known as the Venus in Kôron or in the gardens; it was in the temple of Venus Urania at Athens. In the dialogue of the Portraits, Lucian makes this statue the basis of some of his stories of Alcamenes, and he takes from it the face and hands to contribute towards his ideal portrait of the beautiful Panthèsis, the daughter (according to Wieland's conjecture) of the imperial family-prætor in Asia, and the concubine of the emperor Hadrian, who was the former mistress of the empress Faustina, but was herself only a concubine in (the Roman sense.

Many other ancient writers speak of this statue. Pliny says that Phidias finished it; by which must be understood that he made a few alterations on the finished statue of Alcamenes, which, according to his riper judgment, it required: mere technical finishing is not the work of a great master.

In another statue of Venus, Alcamenes contended with his fellow-pupil Agoracritus of Paros, and the Athenian judges awarded the prize to Alcamenes, not because it was the better work, says Pliny, but because it was the work of their own citizen. Agoracritus was so much hurt at the decision, that he charged Alcamenes with Nemesis, and sent to the people of Rhamnus, on condition that it should not be set up in Athens: and as the Rhamnussian Nemesis was long cele- brated as one of the most famous works of antiquity, and was preferred to all other statues whatever by Varro. The statements about this work are various: according to some, it was made by Phidias for Agoracritus; a report which may have been spread by the Rhamnussians to give the statue more value in the opinion of the world. Pausanias, who saw it at Rhamnus, says that the authors of this work of Phidias, and does not mention the name of Agoracritus.

Agoracritus continued also, according to Tzetzes, with Phidias: the subject was a statue of Minerva; and the work of Alcamenes was at first, on account of its higher finish and previous to the work of Phidias, but was fixed in their destined places, the superiority of the statue of Phidias was evident; the latter gained effect, the former lost it. In this instance, Phidias gave Alcamenes a lesson, from which modern artists might derive a benefit. The great majority of the statues and works of sculpture in the modern world is said to have been made without any allowances for either the elevation or the distance from the eye, of the destined locality of the work: that a work in which this principle is carried fully out is un- known, as the artist has made bad apology for its neglect, though it may satisfy the artist's vanity.

Another celebrated statue by Alcamenes was one of Dionys- us, of ivory and gold, placed in a temple to that god in the part of Athens called Aigion, the part in which the sculptor was said to have been born. It stood in the interior pediment of the temple of Jupiter at Olympia, represent- ing the fight of the Lapithæ and the Centaurs, were by Alcamenes. Pausanias mentions besides at Athens, a statue of the Parthenon, which he represented as painted by the hand of Hecate on the Acropolis, the first in that form; and statues of Proene and Ityæ, in the same place. There was also a Roman and Hespeletes at Athens, in which the lameness was expressed without destroying the beauty of the statue: it is noticed by Cicero and by Valerius Maximus. Pausanias men- tions also an Aesculapius at Mantineæ, and Pliny speaks of a bronze figure of a pentathlete, or in the pentathlon, or five athletic exercises, which was called engrinomemos; these statues were very high, running; the discus, or throw, for- getting the javelin, and wrestling.

(Pliny, Hist. Nat. xxvi. 6, xxvii. 4: Lucian, Imagines, 4, 6, and the note in Wieland's translation; Pausanias, i. 8, 19, 20, 34, 39; v. 10; viii. 9; ix. 11; Cicero, Nat. Fam. ii. 16; and Soestus: Nauk. Maxim. Athens, in the Illustrated Travels of Tzetzes, vol. iii. viii. 193; Winckelmann, Werke, vol. vi.; Thierseh, "Epochen der bildenden Kunst," &c.)

ALCOHOL, Medical Properties of. These are of a twofold kind: first, those in which it is employed on account of its solvent powers, it being, next to water, the most ex- tensively employed solvent, to obtain, preserve, or facilitate the administration of a variety of active principles, vegetable, mineral, or animal; and secondly, those in which it is used as a stimulant, a purgative, or as an agent to counteract poisoning. Besides, it is a solvent, and in the production of various medicinal agents it is employed to dissolve, precipitate, or facilitate the discharge of a foreign substance in the system. It is a stimulant in the same way that wine is, and is capable of being used with much advantage in the treatment of certain forms of disease.

ACER, Medical Properties of. It is a purgative, an astringent, and a styptic. It is also a stimulant, an agent which will remove diseases of the brain, to which it is applied in combination with other medicinal agents. It is also employed as a luminary in the treatment of various diseases.

ALCOHOL, Medical Properties of. These are of a twofold kind: first, those in which it is employed on account of its solvent powers, it being, next to water, the most extensively employed solvent, to obtain, preserve, or facilitate the administration of a variety of active principles, vegetable, mineral, or animal; and secondly, those in which it is used as a stimulant, a purgative, or as an agent to counteract poisoning. Besides, it is a solvent, and in the production of various medicinal agents it is employed to dissolve, precipitate, or facilitate the discharge of a foreign substance in the system. It is a stimulant in the same way that wine is, and is capable of being used with much advantage in the treatment of certain forms of disease.

ACER, Medical Properties of. It is a purgative, an astringent, and a styptic. It is also a stimulant, an agent which will remove diseases of the brain, to which it is applied in combination with other medicinal agents. It is also employed as a luminary in the treatment of various diseases.
A single moderate dose, suitable for the individual, produces effects which are entirely limited to the viscera of the abdomen. They extend themselves from the solar plexus of nerves to the organs upon which the splanchonic nerve is distributed, and are in these a livell action. A feeling of comfort in the abdomen, quicker and more powerful digestion, stronger peristalsis, moderate sweating, but, more abundant secretion, especially augmented secretion from the kidneys, are the common phenomena which result from the lowest degree of its action. A larger quantity, or several small doses a day, can be employed; this has produced increase of the size, increased the roundness of the sphere of the splanchic nerve, even to the spinal chord, the brain, and entire nervous system. The feeling of comfort and warm experienced in the preasocial region is diffused over the whole frame. The pulse is raised, becomes more active, sweats more profusely from the stomach, or on occasion of more case, strength, and capacity of endurance, the tone of the nervous system is raised, the influence of the nervous energy upon the other organs is quicker and more powerful; but, above all, that part of the nervous system whose functions are executed by the brain is most perceptibly increased, as is seen in the greater cheerfulness, humour, and courage, as well as the more active and acute power of thinking. During this degree of action the sensibility to external impressions is unaltered, but those of the aeria are more affected. The nauseous nature of the drug is occasioned by a more eager participation in the incidents occurring or sentiments expressed, and in the expansion of the affections or passions.

Concomitantly with these, all the functions of organic life are carried on more actively; of which we have proof in the increased secretions, especially of the cutaneous transpiration and secretion of urine.

From this view it is obvious that alcohol is an agent which, when used properly, may be most beneficially employed when some portion of the system, particularly the stomach, brain, or kidneys, requires assistance. Hence under the influence of many sedative poisons, alcohol furnishes the readiest and most potent means of surmounting their effects, the prolonged action of which would prove fatal. Some poisons however, particularly those of rancunueous plants, such as muskaboad, probably from their active principle being dissolved by the spirit, have their deleterious influence increased by alcohol, and deprave the blood, and exerted themselves in the frame by its emaseuant, or bitter-smase, the latter with whikeye. Such persons are rarely intoxicated. Many persons with a feele and slow digestion have the process expedit ed by a small portion of alcohol taken after their meals. The employment of which is not probable to those who are prone to calculous disorders, find great benefit from pure alcohol, in preference to either malt liquors or wines. (Frout, On Diseases of the Stomach, 3rd edition, p. 8.) The difference between pure alcohol and alcohol combined with other principles in wines has already been pointed out. (Virrs, P. C. p. 465.) With persons very prone to acidity pure alcohol agrees better than any wines, especially than the sweet wines; and those disposed to the lithic acid diathesis find the same advantageous. (Oedele, in his Hist. Halls, B. C., the 4th ed., p. 132; Heindorf, in his History of the Rhine, B. C., 4th ed., p. 132.) The employment of which however must be habitual, not occasional. Immense benefits would be conferred on the community in this country, if they could be introduced at a moderate price, as the quantity of alcohol in them is very small compared with other wines.

A reference to the chemical composition of alcohol will show that it is a highly carbonized compound. When taken to excess it produces exhaustion of the nervous power and an oppression over the mind. From this point alcohol is a powerful stimulant to the stomach-pump, vegetable acids given freely, occasionally dashing cold water on the face or head, artificial respiration, and very cautious venesection, in some instances restore the sufferer. Liebig says alcohol has not been detected in the urine. With quinsy there is a dangerous source of the disease, which can be all exhaled by the lungs, this may be true; but the presence of alcohol in the blood, brain, and urine has been proved by Dr. Percy. (Dr. Golding Bird, in Medical Gazette, vol. iv. pp. 301, 302.)

ALDEGREVER, HEINRICH, a celebrated German painter and engraver of the sixteenth century, was born at Soest in Westphalia in 1502. He became the pupil of Albert Dürer, being attracted to Nürnberg by the great fame of that artist, and he imitated his style so closely that he acquired the name of Albert or Albrecht of Westphalia, a circumstance which has led some writers to mistake the name of Albrecht Dürer for Albrecht Aldegrever. There can be no doubt of his name having been Heinrich or Henry, as it is so engraved in two different portraits both executed by himself. As a painter Aldegrever executed little. In his early life, he was chiefly employed in engraving. His plates are generally small, and are executed in a very minute and laboured manner, whence he is reckoned among the so-called little masters, of whom he is one of the most distinguished. His prints are very numerous, exceeding three hundred, and they bear dates between 1502 and 1569, which is supposed to have been the year of his death; it is however a mere conjecture. His designs are conspicuous for the sharp and angular lines of the Gothic style; but though hard and wiry, many of his figures display good anatomical drawings. His subjects are sacred and profane. Thirteen plates of the labours of Hercules are among his very best works: they are very scarce. A print of the Count D'Archeambaud, just before his death, killing his son lest he should leave the paths of virtue for the road of vice, is among his most admired plates. Among the portraits engraved by Aldegrever are those of — Luther, dated 1564; Melanchthon; John of Leyden, king of the Anabaptists; and the fanatic Bernard Knipperlolling. He engraved also many designs for silversmiths and for book-sellers.

His paintings are in the same style of design as his engravings, but they impress, still more than his prints, with the feeling of the pains they cost him: his colouring is very high. In the gallery of Berlin there is a small picture of the Last Judgment by him; in the gallery of Munich there is an excellent portrait of a man with a red beard; there are a few of his works at Schlesheim, at Vienna, and at Nürnberg, and at Soest, in some churches.

In a print of Titus Manlius ordering the execution of his son, Aldegrever has introduced an instrument, very similar to the guillotine used by the terrorists of the French revolution; it is dated 1563. (Heineken, Dictionnaire des Artistes dont nous avons des Estampes; Hartz, Printers Graev.)

ALETHOPERIESI (Sternberg), a genus of fossil Ferns, mostly from the coal formation. (Pecopertis of Bronn and Elt.)

ALFINUS VARUS, one of the Roman jurists whose excerpts are contained in the Digest. [JUSTINIAN'S LEGISLATION, P. C.] He was one of the most distinguished pupils of the great jurist Servius Sulpicius, the friend of Cicero. Fonponusus (Dig. i. tit. 2) states that he became consul, and that he is generally said to have been consul a.d. 152, and the same person as the F. Alfinus or Alfinus Varus of Dion Cassius (lib. iv. Index). But as Sulpicius, the master of Varus, was born about b.c. 110 and died b.c. 63, it is not probable that Alfinus the jurist could be consul so late as a.d. 126.

Acron the schollast (Horstius, Sat. i. 3. v. 150) has a story that Alfinus was a shoemaker at Cremona, who came to Rome, where he became the pupil of Servius Sulpicius, and attained such distinction for his legal knowledge that he was made consul and had a public funeral. The passage of Horace and the remark of the schollast have occasioned much discussion (Wieland, Horazas Satiren übersetzt, note on Sat. i. 3. v. 43). It is very difficult to form any conclusion from the passage of Horace, though it may perhaps be assumed that he does refer to the jurist Alfinus; but this will not determine whether the story of his early life as given by Acron and alhed to by Horace is true.

Alfinus wrote a work entitled 'Digesta;' in forty books. He is often cited by other jurists; the excerpts in the Digest show that his style was clear. Gellius (vi. 5) quotes a passage from the third book of the Digesta Varus in the second book of the Collectanea, or Conjectaneas, as it stands in some editions of Gellius; from which expression one might infer either that the Collectanea was a part of the Digesta of Alfinus, or a different work by Alfinus. But it is often an improbable that Alfinus was the author of the compilation of Audifius Nannus (Dig. i. tit. 2) in one hundred and forty books, which he made out of the writings of eight of the pupils of Servius. If so, Gellius referred to the
passage both in the original Digesta of Alfenus, and to the same passage in the Collectanea of Namus.

ALGÆ, FOSSIL. The remains of sea-woods in a fossil state are less common than their probable abundance in the ancient ocean and the generally marine origin of the strata in which they have been found. This arises perhaps from the cellular texture and destructive nature of the marine plants. Traces however of several genera occur in Silurian, carboniferous, liasse, colliert, and later deposits.

ALGADRI, ALGADRO. Italian sculptor and architect, chiefy distinguished however as a sculptor. He was the son of a silk-mercer of Bologna, where he was born about 1600, or even earlier, but the dates given by the various writers who have written notices of him are so contradictory, that it is extremely difficult to give a precise idea of his age or any definite certainty. He entered the celebrated school of the Carracci, but finding that sculpture was more suitable to his taste than painting, he became the pupil of Giulio Cesare Conventi, a sculptor of celebrity in his day. At the age of twenty, says Bellori, he accompanied Gabriele Bertazzuoli, the architect, to Mantua, and was introduced to the duke Ferdinand, with whom he apparently became a favourite, as he received many small commissions from him for models, and was afterwards sent on several important objects. In Rome he was two statues in stucco, for the Capella Bondoni in the church of San Silvestro on Monte Cavallo. He obtained these commissions through the intercession of his friend Domenichino: they were a John Baptist, and a Magdalen, and obtained for him the preference, as he had had the previous year still to depend upon the jewellers for support. His patron Ferdinand, duke of Mantua, died shortly after his arrival in Rome, he quarrelled with Domenichino, and for many years he laid no other occupations as a sculptor than that of restoring ancient fragments. But about 1640 his prospects changed; he was chosen by Pietro Buoncompagni to execute the statue of San Filippo Neri for the sacristy of the Padre dell' Oratorio of Rome; he made a group in marble of two colossal figures, the saint, and an angel kneeling by his side presenting him a book; and he displayed so much judgment and taste in working the marble, that he raised himself to an equality with the most favoured of his contemporaries; and the Cardinal Bernardino Spada, in consequence of the success of this group, gave him a commission to execute a colossal group in marble of two figures representing the decapitation of St. Paul, for the church of the Padre Ber- nabei at Bologna. St. Paul was represented kneeling, with his hands bound behind him, the criminal, enquiring, as he was asked, was behind the saint, with his sword mixed ready to strike. The success of this group was complete; it is technologically a work of very great excellence, but in the attitudes it is forced or affected; it however established for Algardi the reputation of a master, and he was employed in executing many works in rapid succession, chiefly in metal, both for Bologna and Rome. The principal of these were the monument of Leo XI. in Saint Peter's, and Attila checked by Saint Leo, an altoriel of enormous size, for one of the altars of the same church.

Algardi's better fortune commenced after the accession of Innocent X. In 1644, whose niece Costanza Panfilii was married to Algardi's friend and patron, prince Nicolò Ludovisi, the cardinal, henceforward, his works are on a scale. On Camillo Panfilii, another of the pope's nephews, entrusted to Algardi the erection of a villa without the gate of San Pancrazio, now well known as the Villa Panfilii. As an architectural designer he worked of little merit, though it is Algardi's most successful effort in architecture: it is richly ornamented with sculpture.

Algardi executed also the bronze statue of Innocent X. which was decreed by the Roman people or senate in con- sideration of the great services rendered in the Republic. Don Camillo Panfilii, another of the pope's nephews, entrusted to Algardi the erection of a villa without the gate of San Pancrazio, now well known as the Villa Panfilii. As an architect he worked on a scale, it is of little merit, though it is Algardi's most successful effort in architecture: it is richly ornamented with sculpture.

common arithmetic to the complete double algebra, as it may be called, the subject matter of which is capable of representation in space of two dimensions. It is not within human limits to demonstrate every one of those heads; but much has been done in the articles already cited, and by dwelling a little upon the parts which are completely new (as far as this work is concerned), it is probable that the reader who has mastered those articles will be able to supply what is wanting for himself.

1. In pure arithmetic the subject matter is simple number. Its number of symbols is much less than that of a mere geometrical, or the [3—4;] 1, 2, the abbreviation of 1—1; that of 1—1—1, etc. Also the symbols + — and ± of powers and roots. All these symbols have specific meanings, and the symbols of operation are connected with known operations. There are also symbols (not in full, but in part) of operations which will not enter into the discussion of pure arithmetic, that is, each one stands for a definite number, known or unknown, throughout any one train of thought, though it need not represent the same number in all investigations.

2. The fundamental direct symbols of operation, seen in $ax, ab, a^x$, are connected with inverse operations, seen in 

$$a - b, \frac{a}{b}, a^b, b^a.$$

Each inverse operation offers certain difficulties: those of $a ^b$ and $a - b$ are overcome by the introduction of the notion of factors; those of $\frac{a}{b}$ by the considerations in Linnell, P. C., applied to what is called the approximate extraction of roots. But $a - b$ presents cases of special interest, and the impossibility of being removed as long as the symbols are the symbols of pure arithmetic.

3. The rules by which operations of pure arithmetic are performed are found to be capable of classification under five heads: (1) a step by step in any train of thought leads to anything by the use of one of these five simple rules, or of complex rules obtained by their combination. Of course these rules are understood as applied only when they give intelligible results.

4. Rules for signs. Whenever two of the signs $+$ and $-$ both act upon any symbol, the result is that like signs give $+$, unlike signs give $-.$

5. The double rule of signs. In such cases the signs + and — are connected by a symbol, the result is that like signs give $+$, unlike signs give $-.$

6. The conversion of addition and subtraction, as in $a + b - c = b + c - a + b,$ etc.

7. The conversion of multiplications and divisions, as in $a \times \frac{b}{c} = b \times \frac{a}{c},$ etc.

8. The distribution of multiplications and divisions, as in $(a + b + c) = ab + ac + ad,$ etc.

9. Rules of exponents. These are $a^{b+c} = a^b \times a^c$ and $(a^b)^c = a^{bc},$ etc.

Every master of the use of these rules can perform all the steps of any arithmetic, and in that respect Algebra is nothing but a branch of arithmetic, but provided that no steps are entered except those which are arithmetically intelligible. Even the common rules of computation, so far as they are not acts of memory or trial, consist in the use of the first four rules.

On examining problems into which the impossible subtraction enters, whether in process or result, whether from inconsistency in the problem or in the mode of solving it, the impossibility is always to be traced to a diagonally wrong case put upon the meaning of some one quantity, as reading gain for loss, or ascent for descent, etc. And since the impossible subtraction can always be reduced to the form $0 - a$ or $- a$ (thus $3 - 7 = 3 - 3 - 4,$ or $- 4,$ and since this is found of every case where, as a correction, that a unit should be taken of the sort diagonally opposite to what was supposed when $0 - a$ was found, it suggests itself to let $1$ and $- 1$ mean, not merely the addition and subtraction of $1,$ but any two opposite kinds of units whatever [Negative, $- c,$ etc., F. C.]."
also with intelligible meanings. Every such system of meanings, superadded to the symbolical algebra, is a logical algebra, and every process of reasoning or a collection of reasonings. In all probability there is an infinite number of logical algebras to every self-consistent system of symbolical algebra: we merely note down the list of those which have hitherto been traced from the general and purely symbolical algebra.

I. Pure arithmetic, in which the subject matter is number.

II. Single algebra, in which the symbols represent numbers derived from concrete magnitude, considered as being, in every case, in the number of two or of two kinds.

III. Double algebra, the main subject of this article, in which each symbol represents a line of definite length, and in some definite direction out of the infinite number which may be taken in one plane.

IV. Triple and quadruple algebra, in which the quantities are represented in one plane (this subject is in its earliest infancy). V. The geometry of the second book of Euclid, and the corresponding solid geometry. Here AB actually means the area of the rectangle under the lines A, B, and C: the fundamental rules can be demonstrated, and propositions can rigorously be proved. The ordinary and incomplete mode of demonstrating the second book of Euclid must appear, in this particular practice, objectionable.

The complete process of operations, in which the symbols, or as many of them as we choose, are not magnitudes at all, but directions to perform certain operations on a variable quantity. [OPERATION, P. C.]

Let us assume that every symbol admits of explanation for every symbol or combination of symbols. Thus I. just mentioned requires 0 — 1; II. requires \( \sqrt{-1} \); III. is perfect; and IV. may perhaps be made so:

in V., AB means no more than AB, if it have meaning, and A is wholly inexplicable; and VI. is encumbered with difficulties of new and serious kinds as soon as its elements are passed. It may happen that the proper meaning of a symbol or formula cannot be assigned at the commencement of a logical algebra, but can afterwards be deduced from its symbolic consequences. When this is the case, the deduction may be termed an interpretation of the five symbols. This process is the interpretation to which we have alluded, and symbols of which the meaning is laid down from the common interpretations may be said to be explained.

It is impossible that a perfect algebra can be founded on ideas of time, loss and gain, or any in which only two directions can be imagined. Space, from the infinity of directions which it admits, is, as yet, the only perfect medium of explanation. Time before and after a certain epoch may be considered as two directions, positive and negative; and what is there in the ideas of time to which \( \sqrt{-1} \) possibly apply? Again, show us a commercial operation which, performed upon a gain, produces a sort of result which can neither be regarded as a loss or a gain, or which repeated two or more times upon a gain, turns it into a loss—and we should immediately construct a system of commercial algebra, in which \( \sqrt{-1} \) shall be intelligible. But, as yet, the necessary ideas are found in geometry only, which causes some persons to object to the extension of algebra. But these surely forget that even common single algebra must derive its theory of opposition from concrete quantity; — 1, standing alone, is unintelligible in the science of pure number.

12. Remark the manner in which [RELATION, P. C.] the definitions of \( a+b \) and \( ab \) can be given, even in arithmetic, in terms of process, without mention of subject-matter: \( a-b \) requires one to proceed as in \( a \) we proceed from 0 to form \( b \); \( ab \) requires us to proceed with \( a \) as we should with 1 to form \( b \).

13. Let the common symbol of algebra signify a length in a direction in a certain plane, change either of length or direction demanding change of symbol. Take a point \( O \) for the zero point or origin, and let 0 signify that we do not leave that point. From \( O \) draw any line at pleasure for the axis of length, and take a length \( OU \) upon it for 1: continue the unit axis both ways. Draw a perpendicular through \( O \) to the axis of length, and call it the axis of direction: the reasons for these terms will appear in the sequel.

14. Let \( a \) and \( b \) be the direction and length from the origin which is gained by going over first \( a \) and then \( b \); and let \( a-B \) denote that gained by going over first \( a \) and then a line equal and contrary to direction in \( b \). Let \( AB \) denote a line whose length has units equal to the product of the units of \( a \) and \( b \), and the sum of the angles which they make with the unit line for the angle it makes with the unit line. Similarly, let \( AB \) have the quotient of the lengths of \( a \) and \( b \) for its length and \( \pm \) of the difference of the angles for its angle. These definitions are for example open to most objections; if, however, they be all on the unit-side of the axis of length, there is nothing but pure arithmetic; except when an impossible subtraction obliges us either to reject the process, or to enlarge the definition and pass to the opposite side of the axis of length.

16. Make a positive and negative direction on the axis of direction, thus: Choose a direction of revolution in which a line revolving round the origin, and setting out from the one side of the axis of length will be called positive, and which we shall denote by \( + \). Let the unit revolve positively, and let the first side of the axis of direction which it meets be called the positive side of that axis. Let the opposite direction of revolution be called negative, and which we shall denote by \( - \). Let \( AB \) and \( AB \) be the operations of single algebra whenever the two lines are in the same direction. And if all lines be on the axis of length all the four operations are those of single algebra.

17. By \( A = (a, \alpha) \) let us agree to mean that \( A \) signifies a line of \( a \) units of length, inclined at an angle \( \alpha \) to the positive side of the axis of length. Use the notation \( A, B, \ldots \) of measuring angles. Then \( (a, \alpha), (a, \alpha + 2\pi), (a, \alpha + 4\pi), \ldots \), are all representations of the same line \( A \). The peculiar symbols of the new algebra, as long as they are wanted, shall be capital letters; small letters denoting the symbols of the single algebra.

18. The first four of the fundamental rules in § 5 may be easily shown to be true. The geometrical propositions principally required are two. Firstly, that any number of lengths being given and their directions, if we set off from a point through those lengths and in those directions, one after the other, we reach one and the same point in whatever order the lines of progress are taken. Secondly, that if any polygon revolve about one of its angular points, while at the same time it is turned into similar positions which have been changed in the same ratio, the figure always remains similar to what it was at the outset. With these propositions and the following:

\[
(a, \alpha) \times (b, \beta) = (ab, a + b\alpha) \quad \frac{(a, \alpha)}{(b, \beta)} = \left( \frac{a}{b}, \frac{\alpha}{\beta} \right) = (a, -\beta),
\]

which are merely expressions of the definitions, there will not be much difficulty in establishing the first four of the rules.

19. Let the cube, square, round power, \&c., of \( A \), as yet, be denoted in full by \( AA, AAAAA, \ldots \), \&c., and their corresponding roots by \( \sqrt[3]{A}, \sqrt[2]{A}, \sqrt{A} \&c. \). There is then no difficulty in establishing, as in the previous cases, \( P, A, P \&c. \) : That the nth power of the nth root of \( (a, \alpha) \) is derived from

\[
(\sqrt[n]{a, \alpha + (n-1)\pi}),
\]

\( a \) being any integer; that \( \sqrt{A} \) has 4 values and no more; that \( \sqrt[3]{A} \) stands for a unit on one side (say on the positive side) of the axis of direction, and \( -\sqrt[3]{A} \) for a unit on the negative side. Also, as in the article cited, that \( p + q \) and \( p - q \) in the complex number \( A, \alpha \), on the assumption that \( A \) is identical in meaning with \( p + q + (1/p-q) \) and with \( (\cos a + \sin a + 1) \). Indeed, at this point it will be advisable to receive the imperfect system of \( A, \alpha \), called quadratics, \&c., only reading elements of length and unit above, powers at full length, roots with the old radical sign.

20. Why do we not hitherto admit the exponent, and define \( A^\alpha \) to mean \( AA, \ldots \) ? Because we are not prepared with a definition which will include all exponents. In the article just cited, we get the meaning of \( A^{n-1} \) by inter-
27. The meaning of \( \cos^e \) is the line whose logometer is 
\[ \theta \sim \sin \theta \] and its sine \( \cos \) or \( \sin \) the equation 
\[ \cos = \cos \theta + \sin \theta \] is a necessary consequence of the various trains of definition. 
Now as far as we know, the various trains of definition are that the 
meanings of the symbols satisfy the five rules in § 3, it may 
seem to be too much that so remarkable an equation as the last 
should be actually involved in the definitions, instead of being 
the result of a long sequence of reasonings. And in truth it 
is too much in one point: for most of our preceding reasoning 
on the subject of \( A \) would only really to any base 
we might choose for logarithms, and any unit for measuring 
angles, what have we done but prove the preceding equation 
true for any base and any angular unit? And we reply that 
so far as the definition of \( A \) is concerned, our proof is 
perfectly general: but that, on looking back, we find a restrictive 
connexion between the logarithmic base and the angular unit, 
as follows:——It is very easy to see that in our prior definitions, the 

\[ \cos (1, \theta) \cdots (1, \theta) \cdots (m \text{ times}) = (1, \theta) \] 
leads to the following 

\[ \cos a \cdot \sin \theta \cdots \sin a = \cos m + a \cdot \sin m \cdot \sin \theta \] 
in which we may use \( m \) as an exponent, since for the same 
integer, representing a line in the axis of length, the definition 
in § 23 gives \( A = A \cdots \cdot A \) . 
Let \( \theta \) be the angular 
unit; then we have 
\[ \cos (1 + i \cdot \sin \theta) = \cos a \cdot m \cdot \sin m \cdot \sin \theta \] 

But the last is 
\[ \cos (1 + i \cdot \sin \theta) = \cos a \cdot m \cdot \sin m \cdot \sin \theta \] 
and for all integer values of \( m \) and this not merely from 
equation (8), but from comparison of what \( \cos 1 + i \cdot \sin \theta \) must 
mean in the definitions prior to that of the exponent, 

with the complete exponential meaning of \( e \). 
Hence we must have \( l \), the base of the logarithms, connected with 
The angular unit by the equation 
\[ \cos (1 + i \cdot \sin \theta) = \cos a \cdot m \cdot \sin m \cdot \sin \theta \] 
and any base and angular unit which satisfy this condition 
will do. The most simple way of doing this is to take \( \pi = 2 \cdot 71828 \ldots \) 
as usual, and the angular unit such that there shall be \( \pi \) or 
\( 3 \cdot 14159 \ldots \) units in two right angles: but if any one should 
prefer \( \pi = 2 \cdot 71828 \ldots \) for a base, and \( n \cdot \pi = 14159 \ldots \) for 
the number of units in two right angles, he might get into trouble, 
but not into error.

28. Another difficulty, of the sort which arises when the 
result seems above the means employed in the demonstration, 
is that we have a complete system of trignonometry ready for 
demonstration by mere algebraical mechanism, without casting 
a further thought on the meaning of the symbols \( \cos \theta \) 
and \( \sin \theta \), or more on those of \( \tan \theta \), \( \cot \theta \), \( \sec \theta \), \( \cosec \theta \), 
then to make them, by definition, severally mean, \( \sin \theta \cdots \cos \theta \), 
\( \frac{1}{\cos \theta} = 1 \div \cos \theta \), \( \frac{1}{\sin \theta} = \cos \theta \). All we have done 
with the \( \cos \theta \) and \( \sin \theta \) is to take them into our system as 
expressing the numerical values of the projections of a unit 
included at the angle \( \theta \) upon the axes of length and direction. 
We have not even directly used \( \sin \theta \) \( \cos \theta \) \( \theta \) but 
\( \pi \) in our system, and who attentively read Eucied see that he does, 
in the sixth book, prove \( 1 \cdot 47 \) over again, without any use of \( i \), 
showing that all similar figures described on the three sides of a right-angled triangle 
have the two smaller together equal to the greater.

\[ \sin (e \theta) = \cos \theta + \sin \theta \] 
\[ \cos (e \theta) = \cos \theta - \sin \theta \] 
In the above definition of \( \sin \theta \) and \( \cos \theta \) it is clear that 
\( \cos (- \theta) = \cos \theta \) and \( \sin (- \theta) = - \sin \theta \), whence 
the first of the following, being universally true, gives the second:

\[ i \theta + 1 \cdot \sin \theta \cdots \sin \theta \]
Whence we have

\[(\cos \theta + \sin \theta \cdot \sqrt{-1}) (\cos \theta - \sin \theta \cdot \sqrt{-1}) = e^\theta\]

Now, by definition, has 0 \& \infty, or 0 \& 1, or 0, for its logarithm, and is therefore (1, 0) or 1. And the first side is, by consequence, the rule, \(e^\theta = e^{\theta_0} \cdot e^\theta\). If any one, instead of merely applying rules to the equation

\[(\cos \theta + \sin \theta \cdot \sqrt{-1}) (\cos \theta - \sin \theta \cdot \sqrt{-1}) = 1,\]

should proceed to demonstrate the rules upon this instance, he would, in a circuitous way, be led to a perfect geometrical demonstration of \(e^\theta = e^{\theta_0} \cdot e^\theta\).

29. No equation of this system, which hitherto admits of expression, presents any difficulty as to the meaning of its sides, or any combination of symbols for which the meaning is to be found by interpretation. Perhaps one of the most remarkable results of the ancient system of algebra is the equation

\[\pi = \frac{\log (-1)}{\sqrt{-1}}\]

Some algebraical writers have stated that \(-1\) has neither square root nor logarithm, and without further warning have afterwards made the non-existent logarithm, divided by the non-existent square root, give the ratio of the circumference of a circle to its diameter. Others have given fair warning that, in using what they called imaginary quantities, they were appealing, more or less, to experience; seeing that operations so conducted always led to truth, when, by the limit of \(\sqrt{-1}\), the results could be interpreted, they were content to use such an equation as \(\pi = \frac{\log (-1)}{\sqrt{-1}}\) as an instrument of which the power was known, though its mechanism was concealed. In the complete system it is visibly obvious that \(\pi = \frac{\log (-1)}{\sqrt{-1}}\) is one of the logarithms of \(-1\), or of \((\sqrt{-1})^N\).

30. In ordinary working, there is no objection to dropping the distinction between the logometer and the logarithm, there being no difference between the two in operations.

That this system will finally be introduced into elementary instruction we entertain no doubt whatever. But how soon will this take place? The school-books hardly yet teach the interpretation of the negative quantity: so that there would be little hope of the speedy success of the complete system, even if elementary works existed by which to make it known. But truth must conquer at last: and the respect with which the memory will be preserved of the mathematicians who were neither discouraged by the difficulties nor rendered incredulous by the mysteries of the ancient system, will not protect from ridicule those who shall obstinately refuse to see light because there was once darkness, or shall willfully continue in the imperfect system from those who wish the exact sciences to be in all their parts the perfection of reason are at least duties to be delivered. With respect to those parts of the doctrine of series, and of the integral calculus, which still present difficulties, though of a different character from those here treated, the lesson taught by the victory over what was rashly called impossible, which must have required many years to gain, is—Never refuse to examine, and to continue in the examination of, all consequences of the symbolic laws of algebra: there is every reason to hope that the symbols are always right, even though the views of their explanation may require correction.

ALGEBRAIC GEOMETRY. The regular treatment in this as in every other case, cannot be dispensed with by any of our readers who are desirous of acquiring it. But in this article, as in the last, we are led to write by the total want of elementary works to explain a new and useful modification of the mode of viewing a part of the subject. In the body of the Cyclopedia we avoided, as much as we could, articles which presumed, from their outset, a very ready acquaintance with the details of the branch on which they entered. Thus, though we might take for granted much algebra in treating the elements of the differential calculus, and much differential calculus in such an article as Operation, P. C., or Taylor's Theorem, P. C., we endeavored to make every article to which a beginner was likely to refer an elementary exposition as we could. But it may be allowed, in a Supplement, to make some attempt at supplying the omission. And, during the progress of the Cyclopedia itself, we have observed that, though defects are not to be avoided, they are capable of being remedied within our limits of space: and the mere mention of those defects is a sufficient excuse for our assuming in the reader a reasonable knowledge of existing works.

In geometry of two dimensions, the number of co-ordinates is not so great as to make symmetrical disposition extremely necessary at the outset. We should not, for instance, gain much by forming the equation of the straight line thus:—ay + bx + c = 0 instead of \(x = m(a) + b\); in fact, the writers who have preferred the symmetrical course have rather overlaid themselves with symbols, to an extent which makes the burden thus imposed on the memory greater than that from which symmetry relieves it. But it is not so in geometry of three dimensions. There are three co-ordinates to every point; and, as it happens, symmetry, even when obtained by augmentation of the number of symbols, is found to be, on the whole, an assistance in the remembrance of formulæ. According, the equations of the plane and straight line, and formulae connected with them, are expressed with great convenience in the manner of which the following is a summary: the first use of which, as far as we know, is found in the celebrated work of Malus, 'Théorie de la double Refraction,' Paris, 1810, 4to.

1. In arranging expressions containing three quantities or different sets of three, symmetry requires that no one letter shall ever appear at the beginning of one expression without appearing at the end of another; and that in every set of expressions which are formed by combination of pairs, an interchange of any two letters, or of the corresponding pairs taken out of different sets, shall reproduce the same set of expressions in another order, or at most with different signs. Thus, \(a - b, b - a, c - a, a - c, b - a, a - b\) are the same.

2. When there are two equations of the form \(ax + by + cz = 0\), \(ax' + by' + cz' = 0\), the quantities are not given, but their proportions are: and \(x, y, z\) are in the proportion \(bc' - ac', ac' - bc', bc' - ac', ac' - bc'\).

3. An expression of the form

\[(c^2 - ax^2) + (2ax - ay)(c - ay - ax)\]

is identical with

\[(a^2 + b^2 + c^2)(x^2 + y^2 + z^2) - (ax + by + cz)^2\]

4. The form of the equation of a plane \(ax + by + cz + d = 0\); the common form \(a = \hat{A}x + by + c\) is unsymmetrical. The plane which passes through the point whose co-ordinates are \(p, q, r\), which call the point \((p, q, r)\), is

\[\{x - p\} \cdot \{y - q\} \cdot \{z - r\} = 0\]

The plane which passes through the three points \((p, q, r), (p', q', r'), (p'', q'', r'')\), is

\[\{x - p\} \cdot \{y - q\} \cdot \{z - r\} \cdot \{x - p'\} \cdot \{y - q'\} \cdot \{z - r'\} = 0\]

one term of which is enough; symmetry will point out the rest. Remember the order \(pq, qr, rp\).

5. When such symmetrical expressions as \(ab' - ba', bc' - ca', ac' - bc', \text{etc.} \), are to be constructed, the best way is to write down the letters \(a, b, c, \text{etc.} \), under one another, and to calculate from the left to the end, without returning to the beginning. Thus from

\[
\begin{array}{c|c|c|c|c|c|c|c|c|c|c}
8 & 1 & 3 & 8 & 1 & 2 & 4 & 6 & 2 & 0 & 6
\end{array}
\]

we have

30. — 6, — 42

The most convenient form of the equations of a straight line is as follows. Let \((abc)\) be a point on the straight line, and let \(aBc\) be any three quantities proportional to the co-ordinates of the points which the straight line makes with the directions of \(x, y, z\). Then the equations of the straight line are

\[x = a + y(\frac{a}{b} - \frac{b}{a}) + z(\frac{a}{c} - \frac{c}{a})\]

\[\text{where } \sqrt{(a^2 + b^2 + c^2)} \text{ is the distance between } (abc) \text{ and } (xyz).\]

7. The plane whose equation is \(A(x - a) + B(y - b) + Cz = 0\) may be called the plane \((ABC)\), and the straight line which is mentioned may be called the straight line \((ABC)\). Throughout this article capitals are generally proportional to co-ordinates of angles, and small letters are co-ordinates of points. The order of co-ordinates is \(xyz\), and all letters connected with co-ordinates run in consecutive triples, ABC, ABC, ABC, ... But when triplets of pairs are made, as AB, BC, CA, then AB particularly belongs to the co-ordinate which is attached, BC to that of A, and CA to that of B.

6. The angles made by the straight line \((ABC)\) with the axes have for their co-ordinates \(A + \sqrt{(a^2 + b^2 + c^2)}, \text{etc.} \)
and the angle made by the two straight lines (ABC &c.), 
\((AC'BC')\) has for
\[ \frac{\sqrt{A'C' + B'C'} + \sqrt{A'B' + C'B'}}{\sqrt{A'B' + C'B'}} \]
When the lines are perpendicular, \(A' + B' + C' = 0\); and when they are parallel, \(A', B', C'\) are in the same proportion as \(A', B', C'\).

9. The angles made by the plane (ABC  &c.) with the planes of \(px, sz,\) and \(zy\) are \(\angle \frac{A' + B' + C'}{A' + B' + C'}\); the co-

2. The plane (ABC) is at right angles to the line (ABC), whatever \(a, b, c, p, q, r\), etc. be. And the plane (ABC) line (ABC), where \(a, b, c, p, q, r\), are, parallel to \(A', B', C'\). But the plane 

The intersection of the two planes (PQR') and (PQR') is the straight line (ABC), in which \(A, B, C\), are proportional to \(Q'R' - B', R' - P', P' - Q',\) and 

The intersection of the planes (PQR') and the straight line (ABC) is the point whose co-ordinates are 

The equation of a plane which passes through the straight line (ABC) and is perpendicular to the plane (PQR') is 

14. Two straight lines (ABC) and (ABC) do not generally speaking, intersect at all; their shortest dis-

15. The equation of a plane which passes through the straight line (ABC) and is perpendicular to the plane (PQR') is 

16. The perpendicular distance from the point (abc) to the plane (PQR') is 

where the square of the length of that perpendicular is 

This is sufficient for a specification of the method, and even 

17. The perpendicular distance from the point (abc) to the plane (PQR') is 

\[ \frac{A(l-a) + B(m-b) + C(n-c)}{A' + B' + C'}. \]

ALGERIE, L' (pronounced Algerie; Algerie in Eng-

79
pristors, inhabitants of Algiers, the quiet subjects of France, whose property was solemnly guaranteed to them by the capitulation, and who let their lands to Arab or Kahyle cultivators or graziers. (Pichon, Alger sous la domination Française, s.v. 1839; a very interesting book for the history of the area.) The French were detested by the inhabitants of the bodying Moorish dynasty of Tunis with the title of Beys, on their paying an annual tribute to France. The Tunisians were to assist the French in dispossessing the refractory Ahmed Bey of Constantina. The treaty was agreed on by the court of Tunis; by Marshal Clausel, the under-secretary for foreign affairs. Meinhep a niece of the Emperor of Morocco at the head of a body of cavalry overran the country of Tlemcan, upon which Marocco had some antient claims, and he invaded the tribes of the west to place themselves under the protection of a Moslem prince of the Arab race. Clausel sent reinforcements to Oran, and, notwithstanding the paucity of his means, was inclined to adopt hostile measures against Marocco, but he was prevented again by the minister for foreign affairs, General Sebastiani, who preferred resorting to diplomatic means to obtain the evacuation of the district of Trencenec or Tlemcan by the Prince of Marocco, who ultimately withdrew to his own country. General Clausel, dissatisfied with the disappointment he had experienced from the French ministry, returned home in disgust, and published an apology of the acts of his administration. (Observations du Général Clausel sur quelques Actes de son Commandement à Alger, s.v. Paris, 1831.)

The military term at Algiers remained under command at Algiers: a temperate sober-headed man, who did not indulge in the sanguine aspirations of his predecessor. He resolved on contracting his line of posts within a narrower compass. He marched at the end of June, 1831, to relieve the garrison of Medjejah, which was closely blockaded by the Kahyles, and having evacuated the place, retraced his steps to Algiers, fighting his way through the pass of Tenfiche, harassed by swarms of Arab tribes, and arrived in the city by the 25th of July, 1831. He had thus crossed the Medjejah plain to within a few miles from Algiers. He wrote in the following month of August a long but interesting report to the minister-at-war, in which he refuted some exaggerated notions of the partisans of conquest and colonization, which letter is given by Baron Pichon in the appendix to his work, p. 44. Berthozéne applied himself to cultivate the friendship of the sheiks of the Arab tribes, who conceived a high opinion of his sense of justice. Unfortunatel y, after the month of July, 1831, Berthozéne went to Savary, Duke of Rovigo, on whose arrival at Algiers found himself beset by a party who talked loudly of exterminating the natives, or driving them back to the Desert, taking possession of their property, and distributing it among the French colonists. General Berthozéne after his return to France published a very interesting and impartial work: "Disparait Moit à Alger, ou récit des événements qui s'y sont passés depuis le 14 Juin, 1830, jour du départemuent de l'armée Française jusqu'à la fin de Décembre, 1831," Montpellier, 1834.

The administration of Savary lasted little more than a twelve-month. Its character was harsh, prejudicial, and disorderly. It alienated the natives of all races and classes. Several Arabs and Moors of distinction were summarily executed. The Oufias, a tribe of unoffending Arabs in the neighbourhood of Algiers, were wantonly exterminated; and sweeping confiscations of private property took place. The result was a general rise of all the tribes round Algiers and Oran, and the stoppage of all communication with the interior. Pichon, in his work already noticed, and General Brossard, in his "Mémoire présenté au Duc de Dalmatie sur les moyens d'assurer la securité de l'Algére," give much information concerning the dismal period of 1832.

In 1833 Savary left Algiers on account of ill health, and returned to Paris, where he died in June of that year. General Voiron remained pro tempore commander-in-chief of the French forces in North Africa. During the session that year in the Chamber of Deputies, Marshal Clausel, who continued to be a warm supporter of the system of colonization, after magnifying the importance of Algiers to France, which he compared to that of the East Indies to England, asked the ministers about their intentions concerning Algiers.

The president of the council replied, that there was no intention of evacuating the country; that France was at liberty to act as she pleased, being untrammelled by any engagement with foreign powers respecting it; that for the present the government thought proper to confine itself to the possession of the three towns of Algiers, Oran, and Bona, but that it might be thought advisable at a future time to occupy two or three more points on the coast, although there was nothing decided as yet on that subject. With regard to the placing of the French at Algiers, the government was ready to favour them if carried on by private companies, but had no intention to pursue them on its own account, or by its own means. These explanations seemed to give general satisfaction to the Chamber. The reverse derived from Algiers, and even to the inhabitants of the hugget city, was that they had not been consulted, whilst the whole annual expenditure required to keep possession of and administer the country was stated in the Chamber to amount to 80,000,000 francs. The army employed in North Africa consisted of 80,000 men, with 2400 were turbulent characters, chiefly from Paris, who had been formed into a fighting corps. A corps of auxiliary native troops, by the name of Zouaves, was also formed, as well as a battalio of Turks, and a foreign legion consisting of men of all nations.

In May of that year, General Desmichels, governor of Oran, sent an expedition against a tribe of Gharbas or nomadic Arabs, who had advanced to within 15 miles of Oran; the French succeeded in driving the enemy within two or three miles of Oran, and attacked the French outpost, but after some sharp conflict the enemy retired with the loss of 800 men. The Gharbas then entered into negotiations with the French, who restored their women and children. In June the French occupied the maritime station of Arzew, east of Oran, and soon after the more important town of Mascara, by the capture of the western side of the strait of Bona. Abd-el-Kader made every effort to recover Xoxamnem, but did not succeed. There was much fighting between the French and the Arabs in the province of Oran during the rest of the year. On the evacuation of Toulon, in September of the same year, landed a body of troops at Bougieh, and after several days' hard fighting against the Kahyles, who disputed every foot of ground, house after house, and garden after garden, the French obtained a footing at Alençon, which was superseded by an intermediate station on the coast between Algiers and Bona.

By an ordonnance of the month of August, 1834, General Count d'Erlon was appointed governor-general of the French possessions in the African provinces of the interior, and lands by the right of the minister-at-war. An intendant or head of the civil department was also appointed, as well as a commissary of justice at the head of the judicature. The military events of this year were of little importance. There was some desultory fighting with the Kahyles in the neighbourhood of Bougieh, and with the troops of Ahmed Bey of Constantina, in the direction of Bona. The sheik of La Calle, a maritime station east of Bona, on the frontiers of Tunis, made his submission to France. In the year 1835, Abd-el-Kader, Bey of Mascara, whose authority was now acknowledged by all the Arab tribes from the river Shelif to the frontiers of Marocco, entered into an agreement with the French governor of Oran, by which he acknowledged the supremacy of France, and was acknowledged by the French as the emir of the province of Mascara, which included the whole western division of the state of Algiers, with the exception of Oran and its immediate territory, and the other points on the coast which were occupied by the French. The Shelif was thus divided on the east. A sort of commercial treaty was also concluded between the emir and the French. This convention was censured at Paris, as giving a political importance to the Arabic chief, of which he would take advantage to consolidate his power, until he should be able to turn his arms against the French: and so it happened. At the beginning of 1835 Abd-el-Kader crossed the Shelif, and excited the Haidouks and other tribes in the immediate neighbourhood of Algiers to rise against the French. He himself collected a force of 9000 men and 4000 foot, of
which 1800 had been trained as regular infantry, in the neighborhood of Oran. General Trézel, the French governor of Oran, marched against him, and met him on the banks of the river Sig. The Arabs fought well, but gave way at last, and retired in service. General Trézel having lost 240 men, thought it prudent to move next day to the south-east coast; but he was attacked by the Arabs at the Pass of Makta, where he lost his baggage, a howitzer, several caisons, and 500 men either killed or wounded. This disaster was the most serious that could have befallen him in the camp. Abd-el-Kader showed considerable military skill in these encounters.

Marshal Clausel, being appointed by the king to succeed Clausel, arrived at Tlemcen, 18 leagues southeast of Oran. The Duke of Orleans sailed from France to Oran to accompany the expedition, which consisted of about 10,000 men. Abd-el-Kader tried to oppose the French on the banks of the Sig, and afterwards at the pass of the river Harbah, but his men were overcome by French tactics and discipline. He then withdrew into the interior, leaving Mascara to its fate. The French found Mascara deserted by its inhabitants, and plundered by the wild Arabs. Being unable to retain possession of the post, he was ordered by the Duke of Orleans to retreat to the town of Tafna, situated about 100 miles south-west of Oran, near the frontiers of Marocco, and which was now the headquarters of Abd-el-Kader. The Meshowr or citadel of Tlemcen was held by a body of Kooloolis, the sons of Turkish soldiers, formerly in the service of the Bey, who had retained possession of it ever since the fall of the regency. These men were on bad terms with the Arabs, who considered them as intruders, and they looked therefore up to the French for support. The troops of General Clausel, an army of 5,500 men, marched for five days entered Tlemcen, which Abd-el-Kader had evacuated with all the Moorish inhabitants. The Jews and Kooloolis received the French with acclamations. A body of troops then moved towards the mountains east of Tlemcen, where the Emir was encamped, and drove him away into the interior.

Marshal Clausel next marched northward of Tlemcen to the confines of the rivers Tafna and Isser, where he defeated another body of Abd-el-Kader's followers, among whom he picked the defectors. These men had come to join in the Djehel or Holy war which the Emir had proclaimed against the infidels. Clausel, having returned to Tlemcen, found that the Moorish population had re-entered the town. He appointed a native Bey, distributed arms among the inhabitants, and left a garrison in the citadel, consisting of a mixed garrison in the citadel, which Abd-el-Kader had evacuated with all the Moorish inhabitants. Unfortunately, the Emir was misled by exaggerated reports of the wealth of the people of Tlemcen, and of the small force of the French; and endeavored to march against them an extraordinary contribution of half a million of frances, leaving three natives, one of whom was the well-known Moorish colonel Jussuf, to collect it. It appears, that notwithstanding many acts of execution and oppression said to have been committed by these men, they could only exact the sum of £5,000 of these women's trinkets. The Marshal being now better informed, remitted the rest of the contribution, but the conduct of the army at Tlemcen was the subject of severe censure in the Chamber, and there was a communication between Tlemcen and the sea-coast, Marshal Clausel established a fortified camp at the mouth of the river Tafna, occupying at the same time the little island of Ragusa, which lies before the town.

On his return to Algiers the Marshal marched southward against the Kabyles, who had collected in the Little Atlas, and had interrupted the communication with the town of Meleyah. After an obstinate fight he forced the pass of Mount Tensend, and entered Meleyah, where he reinstalled the Bey Mohammed whom he had been appointed by the French. Meantime the French engineers completed a military road from Algiers to Meleyah. Having performed all these things, Marshal Clausel went to take his seat in the Chamber of Deputies, and defend the system which he had pursued in government of Algiers.

Soon after the Marshal's departure the French of the Tafna camp attempted to relieve the garrison of Tlemcen, but they were met on the way by Abd-el-Kader, who obliged them to retreat with considerable loss to their camp, where they were closely blockaded and suffered much from want of provisions. The French then sent an expedition direct to the mouth of the Tafna, under General Bugues, who having learnt on his arrival that Abd-el-Kader had moved in the direction of Oran, marched in the same direction by the coast road, and arrived at the town of Oran, which had been closely blockaded for some time. From Oran, Bugues began his march to Tlemcen, but on arriving there he found the whole country around stripped of all provisions and cattle by Abd-el-Kader, and he was obliged to return to the town of Tlemcen, which lay across the Telgoet Mountains, a road as yet untrodden by the French. At the Tafna the French collected provisions from their transports, with which they loaded 500 camels and 300 miles, to supply the garrison of Tlemcen for some time. Having crossed the mountains and the Isser, they found, on the 6th of July, Abd-el-Kader strongly posted on high ground above the steep banks of the Sikkat river. The Ala cavalry attacked the French as they crossed the ravine, and obtained a momentary advantage, but they were at last repulsed, when Abd-el-Kader advanced in good order with his reserve of regular infantry. This body of men fired with considerable precision, and was driven by the French General, who had been routed and driven in their flight down the precipice into the ravine below, most of them were killed. The native auxiliaries of the French were busy cutting off the heads of the dead, and collecting the bodies of their lives of 180 men, and this was the first instance of prisoners being taken in Africa. This was the first approach to a more humane system of warfare, and it led afterwards to an exchange of prisoners between Abd-el-Kader and the French.

At Tlemcen, Marshal Clausel was committed to the general command of the troops, and Constanz was resolved upon Paris, and Marshal Clausel returned to Algiers to make his preparations. Troops were sent both from Algiers and from Toulon to Bona, where the Duke of Nemours, Louis-Philippe's second son, arrived also to accompany the army. On the 13th of November the expedition, about 7000 strong, left Bona, and after two days arrived at Guelma, an old Roman station on the Seyboos river, where a deposit was established for the sick. The troops then marched to Al-Abs, and entered the well-fortified town of Constantina, when they were assailed by a storm of hail and snow, followed by a sharp frost, which reminded some of the veterans of the retreat from Moscow. Many men died, and others had their feet frostbitten. On the 20th of November the army entered the town of Constantina. Marshal Clausel had been told by Colonel Jussuf, whom he had prematurely appointed Bey of Constantina, that the population of the town would open the gates to him; but he found the garrison, consisting of 500 and 900 men, determined upon defence, and the red flag of Algiers floating over the main battery. He had not the means of investing the place regularly, the snow continued to fall heavily, one-half of the men were ill or were left behind with most of the baggage; and the garrison of the town, with 2000 or 3000 people kept the French outposts continually on the watch. After attempting to batter down with his guns the gate of Al-Cantar, Clausel made a desperate effort, on the night of the 23rd, to force that gate and in front of Er Rabah, in Er Rabah, near Constantina, by which the French occupied the town, and men lost their lives. On the morning of the 24th the French began their retreat in the direction of Bona, followed by the garrison of Constantina, and harassed by clouds of Arab cannon, and the population of the country. The French themselves proceeded to Bona. The official statement of the loss of the French stated it at 453 dead and missing, and 304 wounded. The sick were in still greater number. The failure of this expedition produced a very unpleasant sensation in France. Marshal Clausel was recalled and was succeeded by General Danréanet. Upon the whole, this second period of General Clausel's administration was brilliant and bold in a military point of view, and notwithstanding some reverses, it paved the way for the ultimate occupation of the whole state of Algiers by the French.

In the spring of 1837 General Bugues was sent again to Algiers.

P. C. S., No. 11.
Oran on a special mission to treat with Abd-el-Kader in order to prevent him from joining Ahmed Bey of Constantia, against whom a second expedition on a larger scale was being prepared. On January 18, 1889, the French Army, under the command of General Danormant, took possession of the coast between Bougieyah and Oran, in the country of the Kabyles. General Abd-el-Kader, the representative of Arab nationality, had little sympathy for the Turkish Bey of Constantia, who was besides much inferior to him in character and abilities. Bugeaud, having 9,000 men, made a strong escort to the banks of the Tafna, where he had a remarkable interview with Abd-el-Kader, which Bugeaud managed with considerable spirit and address, and at last a treaty was agreed upon and stamped with the seal of the Bey, dated at Oran, on the 27th of May, 1889. Abd-el-Kader acknowledged the sovereignty of France, retaining the administration with the title of Emir of the two provinces of Oran and Titteri, with the exception of the towns of Oran, Mostaganem, Arzew, and one or two more points on the coast. Tlemcan was given up to him, on condition of his not molesting the Kooloudi and the other friends of France. On the side of Algiers the boundary-line of the Emir’s territories was extended as far as the ridge of the Little Atlas which is nearest to the capital. Medehya of course was given up to him, but Bledah and Cologha remained in possession of the French. The Emir on one part engaged not to code any part of the coast-line to any foreign power, and he also engaged to furnish the French with a cavalry force of 3,000 men and 5,000 mules. This treaty was very advantageous to the Emir, who gained a considerable extent of territory. But the French also obtained their object of being for a time relieved of anxiety from the west, so as to be able to turn all their strength towards the eastern provinces of the country. On the 27th of May, General Danormant arrived at Bona and Guelma to the beginning of October. General Danormant took the direction of the expedition, and the Emir of Nëounou came from France to assume the command in chief. The army met with little opposition in its advance. They formed their batteries on high ground which command the town, and effected a breach in the wall. Upon the 12th of October, the Governor, General Danormant, whilst surveying the operations, was killed by a cannon-shot, by the side of the Duke of Nemours. General Abd-el-Kader, who assumed the direction of the besieging army, and the town was stormed, but the French encountered a stubborn resistance in the narrow streets; the natives sprung a mine, which killed a number of French soldiers, and a high wall which fell down buried many more under its ruins. At last all opposition was overcome, the surviving part of the garrison escaped or threw themselves down the walls of the town, and the Kasabah, or citadel, surrendered soon after. The Duke of Nemours took up his quarters in the palace of the Bey. The soldiers at Oran recommenced acts of violence, but by the exertions of the officers were restored, the Russians were respected, and the inhabitants were assured of protection. Ahmed Bey had left the town previous. Peronneau, a general of the French, established himself in the interior, with a few followers. A native Kaid, or civil magistrate, was appointed, and a French governor and garrison being left at Constantia, the army returned to Bona. The conquest of Oran, and the burning of the suburbs, in which many tribes from the interior, was an important event. It established the French power in the centre of a vast inland region, the antient Numidia, extending to the borders of the Regency of Tunis on one side, and as far as the Sahara, or Great Desert, on the other.

In the following year, 1889, the French sent detachments from Constantia in several directions into the interior, to Milah, Djemliah, and Setef, the antient Statis. The province of Constantia was divided for administrative purposes into two divisions, one of which was given to Bona, and the other divided into three Khiliyas, or Lieutenant Sahels, Sahel, Ferjuda, and Majanah. Native officers were placed at the head of each, to administer justice and collect the tributo from the various tribes. The division of Bona was subdivided into four circles, Bona, Tlemcan, Constantia, and El-Kedira. The head of each circle a French military officer, and a native chief under his orders, were placed. The French occupied the maritime station of Stors, the antient Rousaca, the nearest landing-point to the port of Constantia, and near it they built a town which they named Philippville.

Meanwhile Abd-el-Kader was busy in subduing some remote tribes in the south of his province, which would not acknowledge his authority. After the ratification of the treaty, he sent a detachment to unite with the head of each of the three Khiliyas, and then proceeded to Ain Madh, about 200 miles inland, on the borders of the desert, the Marabout of which had refused obedience to him. He besieged the place for several months, and at last took it by capitulation, in January, 1889, and he sent to General Valdo a journal of his expedition in French, which was written by M. Léon Roches, a young Frenchman commissioned by General Danormant to be secretary. Abd-el-Kader was also forming a cordon of stations in the interior, upon which to fall in case of future reverses: at Boughar, about 40 miles south-east of Medehya; at Messaou, on the road to Constantia; at the south bank of the Shelf; at Saidia, south of Mascara; Tafnez, south-east of Mascara; and Tefzra, south of Tlemman.

In the spring of 1830 the French took possession of Jijel, and immediately established a military station on the coast between Bougieyah and Stora, in the country of the Kabyles. In the summer of 1831, the Bey of Constantia occupied permanently Djemliah and Setef, which last became the head town of the new khaliya of Meliana. In September of the same year the Duke of Orleans arrived at Algiers, and then proceeded by way of Philippeville to Constantia, where he received the homage of the various khaliyas and chief men of the province, as well as of the Ulemas with the Mufif at their head, and of the various corporations and tribes of Constantia. He distributed to several native chiefs the decoration of the Legion of Honor, which he had worn in the service of General Danormant. He proceeded with an exploratory expedition in the direction of Algiers, by way of Milah, Djemliah, Setef, Sidi Embarka, and then through the Billion or Iron-gates, a remarkable defile, and then up the river Tafna, which issues from the rocks from 800 to 900 feet high, a sort of Cheddar cliffs on a more gigantic scale, which the Turks had never been able to pass without paying tribute to the neighbouring tribes. The French met with no opposition, and then by way of the river Jamna and Wadi Zeltun to reach the coast.

There is a well written report, published in 1839, by M. Blanqui, of the French Institute, who travelled through the French possessions in Algeria for the purpose of inquiring into the social and economic conditions of the country: Le Rapport de M. Blanqui, Membre de l’Institut, à l’Academie des Sciences Morales et Politiques, sur la Situation Economique de nos Possessions dans le Nord de l’Afrique. He describes in lively terms the failure of all attempts at colonization in the Medjda plain, and the measures he believes the government to take to the towns of Bledah and Cologha, with their splendid orange, almond, and olive plantations, well irrigated, from the capricity of the squatters and adventurers who had ruined a number of pretty country-houses and hamlets on the Sahel, or table-land round Algiers; he speaks of the alarming mortality among the French troops in the country; he censures the tariff of the customs; he seems pleased with the bustling and life which he perceived about the town of Algiers, which assumes rapidly the appearance of a European town; he laments the stillness and solitariness which he found in the eastern province, at Stora, Philippeville, Bona, and Constantia. On the road from Stora to Constantia, a distance of 20 leagues, he gives a picture of the two roads, the one for the sure or the eye; for many a mile there is not a shrub, not a plant to be seen. The aspect of this undulating barren and deserted region reminds the traveller of the Campagna near Rome. 'The whole of the northern coast-line is the highest point of the system of administration different from that of the rest of Algeria. The old civil constitution of the country has been respected, and European colonists are forbidden to enter the province. The French rule through the means of native authorities, khaliyas, imams, and sheikhs, who have received the investiture of their office from the governor, and have sworn fidelity on the Kora. They retain their former authority, except the power of inflicting death. They raise the taxes and tributes, to which they are liable, in the name of the French, for the maintenance of one-third of the gross amount for their troubles. This understanding prevails between them and the French military, who on their part maintain the strictest discipline. M. Blanqui accompanied the Duke of Orleans to Constantia, and saw all the principal native authorities and other inhabitants of the prince. He remarked that their appearance and manners were far superior to those of the Arabs of the province of Algiers. The whole population of the town he reckoned at about 10,000. The whole appearance of the town was that of a little miserable, dirty, and decaying. He considers it important only to have an advanced military post in the interior, but the doubts whether it is worth keeping. The whole report is very interesting, and is one of the best written papers we have seen on the state of the country. It is reprinted in a graceful volume by M. Blanqui. While Kader ruled over half of Algeria, several of the author’s reflections and suggestions are now out of date, in consequence of the events that have happened since. This document has
been inserted in the appendix at the end of Lescot's 'Annuaire Historique Universel' for 1839.

In October, 1839, the Arabs of Abd-el-Kader resorted however, to Bazille, to cattle, and by this they any previous declaration. They invaded the Mejidia, and surprised and cut to pieces the French colonists, as well as several detachments of soldiers. A subsequent letter of Abd-el-Kader to Marshal Valée was mounted on a raid, and the tribes are again in the south. The Algers were defeated near Bledah, and the Marocco, near Tazn, on the road to the great desert. From his place of retirement within the frontiers of Marocco, Abd-el-Kader not only strove to keep the possession of the tribe of Algiers, but he likewise succeeded in exciting the fanatical population of Marocco itself to a holy war, for the purpose of driving away the infidels from Africa. Some of the emperor's family and court joined in this war. The French, however, had gained a footing between Marocco and the French. Marshal Bugeaud has added to his former successes that of defeating, at the battle of the Ili, the army of Marocco, which had advanced into that part of the territory of Algiers which lies west of the Tafna river; after which the French seized upon Ouehs, a frontier town of Marocco. These events, and the bombardment by sea of the towns of Tangier and Mogador, induced the emperor Abd-el-Rahman to sue for peace, the principal condition of which is that he will not permit his subjects to make any more the French in possession of Algiers. In the debates which took place, both in the British Parliament and in the French Chambers, it was elicited that the French dominion of Algiers has been so extended in both North and South Africa, that on its part, having engaged not to extend its conquests beyond the boundaries of the Algerine territories, either on the side of Tunis or on that of Marocco. Perhaps the best security for this is, as was freely stated by the Journal des Découvertes, that France will not conquer Marocco for the best of reasons, namely, that she cannot afford to do it. 'France,' observed the Journal, 'is already obliged, in order to retain possession of Algiers, to keep there an army of nearly 100,000 men, and to have some 40,000,000 francs every year, and she would require double that contingent in order to effect the conquest of Marocco.' It will take many years of peace before the revenue of Algiers can be raised so as to cover its expenditure, and it is even very doubtful whether it will ever be able to do so. In the year 1840, the revenue of Algiers is undoubtedly of considerable importance to France. Mankind at large, and the nations that border on the Mediterranean in particular, have derived one great advantage from the French conquest, namely, the termination of a century of piracy and the final abolition of Christian slavery.

The high administration of the 'Algérie,' or State of Algiers, is by the king's ordinances managed as follows:—A governor-general, who is a military officer of high rank, has the supreme command of all the civil and military forces, and is also the head of the civil and political administration. He is under the orders of the minister-at-war at Paris, where a department of the War Office is especially engaged with the affairs of Algeria. The governor-general of Algiers is assisted in his duties by a council of administration, consisting of the director of the interior, the commandant of the naval force on the Algiers station, the military intendant, the attorney-general, and the director of the
finances. A secretary-general of the government attends the sittings of the council; the director of the interior has under him sub-directors at Oran, Bona, and Philippeville. Algiers, Oran, Bona, and Philippeville have municipal councils and maires. In the other towns, as at Constantina, there are civil commissioners, most of them Albanian.

The country is divided into three provinces. 1. Algiers Proper, which includes also the old division or province of Titteri. 2. Oran. 3. Constantina and Bona. The principal military stations are: Algiers, Bône, Philippeville, Oran, and Ténez. Algiers has a customs department, and a number of forts, Bôned, Moledy, Milliana, Coléah, Shershel, and Boujeyah. In the province of Oran—Oran, Mostaganem, Arzew, Ténez, Mascara, El Esmoun, Tiemcen, Messerghi, Mazagran, Tiaret. In the province of Constantina: Constantina, Bône, Guemâa, Philippeville, and La Calle. Algiers, Oran, Constantina, and Bône have each a considerable garrison and staff. The naval stations are—Algiers, Oran, with the fine bay of Marsa-el-Kebir, Bône, Shersheh, and Ténez.

For the department of justice, there are courts in the first instance at Algiers, Oran, Bône, and Philippeville. Appeals are made to the Royal Court, which sits at Algiers. There are justices of the peace at Algiers, Bôned, Bône, Oran, Philippeville, and Constantina. Algiers has a tribunal of commerce, and the rest are.

The public instruction is under an inspector. The establishments for instruction are—a college at Algiers with 15 professors; gratuitous courses of Arabic, both vulgar or oral, and Arabic school, at Bône. There is a Roman Catholic bishop of Algeria, and there are consistory for the Protestants at Algiers and Oran.

The European inhabitants, not military, settled in the various towns of Algeria, amounted in 1843 to about 60,000, and those of English or Scotch extraction were about one thousand. French villages have been built on the Sahel, or table-land round Algiers, each of which contains from fifty to sixty families of French colonists, chiefly emigrant farmers with a small capital. The government has granted them allotments of ground, on condition of their cultivating them and building their own houses. These villages have been surrounded by a ditch and towers, thus forming a chain of fortified outposts round the capital. Each village has its fountain, its church, a public house, and a school. The villages, therefore, have been built by private individuals near Bôned and in other places. At Ténez on the coast, about 90 miles west of Algiers, a new European town has been constructed outside of the old Moorish town. From Ténez a road has been made to Or- blouanville, an inland colony of 500 or 600 inhabitants, with a military garrison. More to the east is Miliana, a town built on the declivity of Mount Zakar, more than 2000 feet above the sea, and occupied in the war against Abd-el-Kader, but has since been restored on a much improved plan, and is an important garrison town.

Marshall Bugwood stated lately at a public dinner given to him by the merchants of Marseille on his return from Algiers, that the question of safety prevailed in Algeria, that the public revenue has risen to twenty millions of francs, and that the European population amounts to 75,000 individuals, and is daily increasing. It appears by the newspapers, that in the budget for 1845-6, just laid before the French Chambers, the receipts of Algeria are estimated at six millions and a half of francs, and the expenses of the war department are estimated at 74,465,527 francs, for 60,000 men and 15,896 horses. It appears that one half of the emigrants to Algeria are natives of Spainiards, Germans, Italians, and Maltese. A regular communication by steam-boats has been established along the coast, between Algiers and Bône on one side, and Algiers and Ténez on the other. A diligence runs between Algiers and Bôned in the interior. (Guide du Voyageur en Algérie, contenant l'Annuaire de 1844 et les Lois, Ordonnances, et Arrêtés concernant la Colonie, a very full written and instructive compilation; L'Algérie et le Maroc, 1838; Histoire de l'Algérie, 1831; Histoire de la Régence d'Algérie, 3 vols. 1833; Moniteur Algérien; P. B. Lord, Algiers and the other Barbary States, 2 vols. 1835."

ALIEN. On the 6th of August, 1844, an act was passed (7 & 8 Vict. c. 68) to amend the law relating to aliens. It repeals the clause of 1 Geo. I. c. 4, which enacted that every naturalization bill shall contain clauses to the effect that no person naturalized should be a member of the Privy Council, or of either House of Parliament, or hold any office, civil or military, or be capable of holding grants from the crown, of lands, tenements, and hereditaments, either in his own name or by the right of any other person, until he has been a naturalized person born out of her majesty's dominions, of a mother who is a natural-born subject of the United Kingdom, is rendered capable of taking either real or personal estate by devise, purchase, gift, descent, or inheritance, in the United Kingdom, and a friendly state may take and hold every species of personal property, except chattels real, as fully and effectually as natural-born subjects. The subject of a friendly state may also, for the purpose of residence or occupation, either by himself or by his servants, in the United Kingdom for twenty-one years, and not exceeding twenty-one years; and may enjoy the same rights, remedies, exemptions, and privileges (except the right of voting at elections for members of parliament) as if he were a natural-born subject. An alien residing in the United Kingdom may be naturalized by marriage. The privileges conferred upon aliens by this act may be seen by referring to the former disabilities of aliens. [ALIEN, F. C.] Such of the provisions of the following acts which are still in force are—Mariners Act, 5 Will. III. c. 2; 1 Geo. I. sess. 2, c. 4; 14 Geo. III. c. 84. The Alien Act of 1844 also contains a new provision for the naturalization of aliens. An alien who comes to reside in the United Kingdom with a view to residence or occupation, under the following circumstances, is entitled to claim all the rights and privileges of a British subject, except the capacity of being a member of the Privy Council, or a member of the House of Commons, and except the rights and capacities (if any) specially exempted from and by such certificate. The certificate must be enrolled in the Court of Chancery, and within sixty days from its date the memorialist must take and subscribe an oath of allegiance. The course of proceeding to be adopted by aliens wishing to become naturalized is to be regulated, so far as details are concerned, by the secretary of state, and the amount of fees is to be fixed by the lords of the treasury. Persons naturalized by marriage under the provisions of this act, and who have resided in this country for five successive years, are entitled to all the rights conferred by the new act.

The act at present in force for the registration of aliens is the 8 Will. IV. c. 11, which repealed an act of a similar kind 7 Geo. III. c. 70. Subject to the reservations above mentioned, all parts are to declare what aliens (mariners navigating the vessel excepted) are on board or have landed, under a penalty, for omission or for false declaration, of 200l., and 10l. for each alien omitted. Every alien residing for more than one month is required immediately to exhibit any passport in his possession to the chief officer of customs at the port of disembarkation, and to state to him, either verbally or in writing, his name, birthplace, and the country he has come from, under a penalty, for neglect or refusal, of 5l. The officer of customs is to register this declaration, de-
...the certificate to the alien, and transmit a copy of the de-...
supercritical if allowed to spread. This seems to depend on its strong affinity for water: hence it acts as violent corrosive poisons, and are never used in a pure state, save in surges of its use when to form gaseous mixtures. Diluted with oils they constitute rubefacients, particularly ammonia. Their causticity is also greatly lessened by combination with carbonic acid, and is more subdued by an excess of the acid; hence bi-carbonates are less caustic than the corresponding carbonates, and the latter are the bases.

The carbonic acid is apt to fly off on exposure to the air, so that they regain their causticity. Carbonate of ammonia will altogether disappear if not kept in a well stopped bottle; this tendency is one source of its use when used as uncombined salines. Diluted with water or by combination with carbonic acid, so as to be safely applied to the tongue, alkalies have a taste peculiar, and to most persons unpleasant, which is not only so powerful as to be similar to burning when it is thought to liken it. Ammonia and its carbonates are likewise pungent. They exercise an immediate influence on the fluids of the mouth and alimentary canal, as far as they pass unchanged. They neutralize all acids they meet with in their course, and render the muses, and perhaps some other secretions, thinner and more watery. That they are readily absorbed into the circulating mass, on which they have a marked influence, is certain; but they are for the most part quickly eliminated, their effects seem to be limited to the fluids within which they are thrown out of the system. Many alkaline compounds, as well as the uncombined but diluted alkalies, increase the secretion of urine, and change its nature if long persevered in, altering it from an acid to an alkaline state. This is particularly the case when a bicarbonate is used, one of the carbonates, and of vegetable acid with the base, all of which are decomposed in transit, as first remarked by Sir Gilbert Blane, and produce on the urine and the system generally ultimately the same effects as the pure alkalies. The alkalies possess a power of rendering albumen soluble: unboiled white of egg is an albuminate of soda. The albumen of the blood is rendered more fluid by alkalies; hence in excess they impair the physical power of that fluid.

These and all that are requisite to form a correct estimate of their therapeutic powers and employment. Their caustic and rubefacient properties fit them for external use. Their internal employment is regulated by a variety of indications, but it is chiefly as antacids, or to counteract acidity in the stomach and prismatic visae, as diuretics, and to dissolve calculi in the kidneys or bladder, as a refrigerant or cooling medicine in inflammatory diseases, that they are used. Many persons, soon after food has been taken into the stomach, are distressed with heartburn and other signs of indigestion, and either have the urinary secretion in an unhealthy state, or, if they be of a gouty disposition, have frequent attacks of gout. Such persons feel relief by taking some alkali or a mild diuretic, or having their urine made alkaline; and the use of alkali is still more pronounced to those who desire to prevent the formation of uric, as well as the proper quantity to be taken, requires much judgment. Assuming that some alkali is proper, Sir B. Brodie thinks from three to four hours after each of the principal meals, especially dinner, the most suitable time. (Lectures on the Medicinal Use of the Alkalies, ed. p. 203.) Dr. Prout makes a similar remark with respect to alkaline mineral waters. A variety of circumstances regulate the alkali to be selected. From their greater causticity they are in a greater degree injurious in cases of difficult labour, those of a long, or even when taken in such bland vehicles as veal broth. The alkaline carbonates are better borne, and bi-carbonate of potass more easily than carbonate of soda. Their unpleasant taste constitutes an objection with many; this is in some degree lessened by absorbing them in fruits, with which they are often conveniently disguised by Mr. Brockedon, or in an effervescing state with an excess of alkali, as recommended by Sir Gilbert Blane. If taken unnecessarily or persevered in too long, must be considerably done with. The carbonate of soda, for instance, is reduced to the state of acid carbonic, and as such when used as uncombined salines, diluted with a deposit of the phosphates, as indicated by a white, salted sediment, or an indescribable pellucid on the surface of the urine, but much general debility is caused.

Other ill consequences follow the too liberal use of alkalies: they alter the quality of the blood. After some time the patient is liable to pectiche; he perspires too easily, becomes insipid, apprehensive, susceptible of all inflammations, and, in short, is an almost perfect victim of the "burning desire of evil." (Brodie, l. c. p. 292.) As effervescing or saline draughts, made with a vegetable acid and some alkaline carbonate, are much used at the beginning of inflammatory diseases, the following prescription is worth mention: A grain of the compound, in very hot water, should be given by every person against the abuse of these, yet for such are they unfortunately most employed. Weak vegetable acids will be found more beneficial.

ALK. LOIDS—Medical Properties of. These substances, which modern chemistry has made known, are termed sometimes vegetable alkaloids, as being hitherto found exclusively in vegetables, and also organic alkaloids, from requiring a vital power to effect their formation; but the name given to them above is the most appropriate. They are the properties in the lowest degree, and are either tasteless or have a bitter acid taste, existing generally in a solid, mostly crystalline form; some however are amorphous (Ammonitine), occlusive, or vege-morphous (depolev), which form is very volatile, and readily undergoing decomposition, with an evolution of ammonia, at a moderate temperature. The point in which they differ most from the common alkaloids is their affinity for nitrogen in their composition, one of the constituents of the organic (Caffeina) and inorganic (Carbonic acid) compound known. Sometimes one only exists in a plant, sometimes several in the same plant, e. g. opium. Generally they are combined with an acid; most frequently it is a peculiar acid. Many of them are with difficulty dissolved in water, more so in alcohol; they rarely completely neutralize acids, but the salts which they form are more soluble than the bases; hence various of their salts are used in medicine in preference to the primitive article. Their characteristic is the extraordinary action most of them have on the human system in a very small dose, and indeed several of them are, in very minute quantity, deadly poisons. No remedy, devoid of nitrogen, possesses a poisonous action in a similar dose; but it is certainly not in direct proportion to the quantity of nitrogen. Solanias, and picrotoxias, which contain least nitrogen, are powerful poisons. Quina contains more nitrogen than morphia. Caffeina and theobromina, the most highly nitrogenized of all vegetable alkaloids are not so injurious as the former. (Liebig, Animal Physiology, 1st ed. p. 177.) This author conjectures that they owe this great power to having a composition analogous to that of the nerves and brain; but points so hypothetical need not be dwelt upon to the understanding of the question.

Having been first detected in plants long used as medicines (Cinchona), it is chiefly among medicinal plants that they have been sought after and found. By many they are regarded as the active principle of those, and their extraction has had the great advantage of enabling medical men to administer their remedies in a smaller bulk and more convenient form. As the most important of them have been already treated of under the names of the plants which yield them, it is not necessary to notice any of them further here; except to state that chemists have recently rendered a great service in forming a neutral sulphate of quina, which is much more soluble than the diaphane.

ALLAN, DAVID, called the Scottish Hogarth, was born at Allola, in the parish of Holborne, near the Maidstone, in 1744, where his father was shoemaker. The choice of his profession was partly owing to an accident; he burnt his foot, and while he was being nursed at home, having nothing else to do, he amused himself with drawing. He afterwards entered for a time the university, and there he got so much attached to that, when he recovered he had a very great objection to going to school. But he soon obtained a happy release from this obligation, for his old schoolmaster turned him away from the school, for making a caricature of him; but what Mr. Allan likes best is to see him well done, for himself. He was apprenticed to Mr. Stuart, the collector of the customs at Allola, was so much struck with it, that he recommended Allan's father to send him to the academy of Robert and Martha Faulis, to learn drawing, painting, and engraving. Allan remained at this academy nine years, and when he re-
turned home, he had the good fortune to be introduced by Lord Cathcart as a native prodigy to Erskine of Mar, on whose estate he was born, and by whom he was generously set as a pensioner to prosecute his studies at Rome. At Rome he lived under the protecting eye of Gavin Hamilton, to whom was due a great assistance to him in his professional pursuits. Allan proved himself worthy of the generous patronage he enjoyed: he raised hopes however at Rome which he never realised afterwards.

He first received a silver medal for a drawing in the Academy of St. Luke, and afterwards the gold medal for painting. The subject was the legend of the Corinthian maid who drew the profile of her lover around his shadow cast by a last sun's lingering picture was worked up into a good engraving of it by Canego spread Allan's reputation throughout Italy; and his praises reached even his own countrymen; it was however the first and last good picture he ever painted. His subsequent works were distinguished for the advisement of feeling, but in execution, whether as paintings or engravings, they are very inferior.

He painted two other pictures at Rome, the Prodigal Son for Lord Cathcart, and Hercules and Onophaele for Erskine of Mar; and he made also four humorous designs illustrating the Roman Carnival, which through Paul Sandby's prints of them became very popular, and they gained Allan a considerable reputation for broad humour. But he no more deserved the title of the 'Scottish Hogarth,' which for these few broad prints he was permitted to coin, than his historical pictures would warrant his being called the Scottish Raphael. 'He is among painters,' says Allan Cunningham, 'what Allan Ramsay is among poets—a fellow countryman in any tailoring in all but spirit of rustic droolly, but deficient in the sensibility of conception, and little acquainted with lofty emotion or high imagination.'

In 1777 Allan visited London, which however he left for Edinburgh, after practising there for a short time as a portrait painter. After the death of Runnemede in 1786, Allan succeeded him as master of the Trustees' Academy, which office he held for ten years, until his death in 1796. He left a son and daughter; the former went in 1806 as a cadet to the Royal Military Academy, Woolwich.

Allan's most popular designs are his Twelve Illustrations of Ramsay's Gentle Shepherd, which be engaged himself in aquatint, and published with an edition of the poem, with some prefatory remarks, as a sort of apology for the humbleness of the style of his designs. He made also some designs for the lyric poems of Burns, which complimented the painter in his letters to his friend Thomson, on more than one occasion. Burns also found fault with Allan's stock and horn,' a rude manner of instrument which he put into the hands of some of his characters. Burns often says, 'Get thee for a shepherd the used in the brases of Atholl.' 'If Mr. Allan chooses,' says Burns, 'I will send him a sight of mine, as I look on myself to be a kind of brother brush with him.' But neither are his original sketches clear of divergences, and the slight difference that I look on Mr. Allan and Mr. Burns to be the only genuine and real painters of Scottish costume in the world.'

Allan however did not think that Burns's stock and horn were a humour appropriate to his own; he said it was only fit for 'reading and roasting.'

In another letter, Burns, speaking of Allan's illustrations of his works, says, 'Wool and married an' a' is admirable; the grouping is beyond all praise; the expression of the figures, consummately delicate, is absolutely faultless perfection. I next admire Turnermipe.' Others of these designs which were successful were the 'Gaberlunzie Man,' 'Maggie Lauder,' and 'John Anderson my Jar.' Allan designed several designs of another description, as the Escape of Queen Mary from Lochleven Castle; several homely scenes, as the Scotch Wedding, the Highland Dance, the Repentance-Stool, &c., and some sketches of Scotch scenery.

(From 'The British Painters,' &c.)

_ALLEGATION, ECCLESIASTICAL_ is the term applied to the first plea in litigations ecclesiastical: in criminal proceedings (ecclesiastical) the first plea is called _allocution_; in plenary or ordinary causes the first plea is called the _defension_, which is a statement of the law or of the common law or to a bill in equity. The term Allegation is also applied to every subsequent plea, in all causes. The first plea given in by a defendant is called a _Responsive Allegation_; the plaintiff's answer to that is called a _Counter Allegation_. The headings are not usually carried beyond this step. Besides these allegations, either party in the case is allowed to except to the credit of any witness upon matter contained in his deposition. These exceptional allegations, when admitted, are proceeded upon in the same manner as other pleas.

(Phillimore's ed. of Burn's _Eccl. Law._)

ALLEN, JOHN, M.D., a writer on subjects connected with metaphysics, history, and physiology, was born in January, 1770, at Redford in the parish of Colliston, near Edinburgh. The seat of his family, called Townfield, is at Redford, situated on the slope of the Pentland hills, was his birthplace. The mansion-house still attests the moderate but substantial wealth of his ancestors. He studied at Edinburgh, where he took a degree in medicine in 1791. He soon afterwards continued his studies in London, and entered into a connection of parliamentary reform, which called down the vengeance of the government. In 1795 he published 'Illustrations of Mr. Hume's Essay concerning Liberty and Necessity,' in answer to Dr. Gregory of Edinburgh, by a Necessitarian. This small tract is in many respects characteristic of his subsequent more distinguished works, in the felicity with which it adopts a broad and comprehensive view, as well as in the clearness with which it adheres to one unbroken line of reasoning, and keeps to the same ground in all his arguments.

It is an exposure of the fallacious assumption that Hume's theory of cause and effect did not make allowance for uncaused causes. This celebrated theory had been deemed a principal one in his system, in nature, that in all cases the same event is caused by following those apparent effects. Gregory's attack was made in diatribes, and Dr. Allen's answer was in the same form, showing that Gregory's reasoning was accurate, but his description of Hume's system erroneous. He stated the doctrine of the common man in a manner simple, and in that simplicity of style he the trueprovince of a popular writer. Without the help of the friendship he enjoyed, 'An Introduction to the Study of the Animal Economy,' it appears to have been about the commencement of this century that he formed an intimacy with Lord Holland, with whom he continued to reside until that nobleman's death. The connection between the two he was permitted to have rested on the foundation of common tastes and opinions and mutual esteem, not on patronage on the one hand and servility on the other. After the peace of Amiens Dr. Allen accompanied Lord Holland to Ireland, and resided with him and Spain, and resided with them in the latter country until the year 1805. He made large collections relating to the past history of Spain, and to its social and political position. He had formed high hopes of the prospects of the Spanish people—hopes destined to be bitterly disappointed, as each effort to regenerate them sunk under anarchy and despotism, and the mortifications to which his zealous feelings in their favour were exposed, appear to have in his latter days damped his ardent admiration for two institutions of whose far reaching influence this extensive contributor to the 'Edinburgh Review,' on subjects chiefly connected with the British constitution, and with French and Spanish history. Forty-one articles in that periodical are attributed to him, and they will serve to establish and characterize his opinions on constitutional questions. His earliest papers were on Spanish and South American subjects, and among those attributed to him are—'Bourgeois, Tableau de l'Espagne Moderne,' October, 1804; 'Helm's Travels from Buenos Ayres,' October, 1806; 'Mercurio Peruano de Historia,' &c., January, 1807; Molina's account of Chili, July, 1809; Laborde's View of Spain, October, 1809; Humboldt's 'Essai Politique sur la Nouvelle Espagne,' April, 1810, and his poem on the History of England by Lingard, which occasioned a pamphlet controversy with that author, chiefly relating to the massacre of St. Bartholomew, the authorities for which charged Lingard with having roused the populace. The latest article which he is supposed to have contributed to the Review is that on Church Rates, October, 1839. He wrote the History of Europe in the Annual Register for 1806; and in 1809 a 'Biographical Sketch of Mr. Canning.' In 1819 he published a small work on Parliamentary constitutional work, called an _Inquiry into the Rise and Growth of the Royal Prerogative in England_. He maintains that by the older constitution public acts were not performed by the English kings until after their coronation; and it is a remarkable circumstance of a general constitutional doctrine stand-
ing the test of minute chronological inquiries, that while Dr. Allen states the reign of Richard I. to be the only exception to this practice; Sir Harris Nicolas, in his ‘Chronology of British Painting’, 1727, has deduced other collections of documents, the regnal years of that reign are antedated by a year. Dr. Allen published several other pamphlets, some of them on subjects of comparatively temporary interest. He was a member of the Royal Society, and the only other person he ever appointed was that of under-secretary of the commissioners for treating with America in 1806. He died April 3, 1843. He left his medical books and MSS. to his early friend Dr. John Thomson, of Edinburgh—and his other MSS. he bequeathed to Colonel Fox. W. believe it is in contemplation to print a collected edition of his works. His character has been eloquently drawn by his friend Lord Brougham, in the third series of the ‘Essay on the Euphones of the Statesman of the time of George III.’ p. 342-348.

Judith. His, his, 1829. The 1806. Heretic. Magdalen, is establishing it the (Pharmaceutical galvanic desirable his Philosophical Plough-court, cleaning Historical 5000/.

Allen’s, both in oil and fresco, are numerous, and many on a large scale; his greatest work is the Montagni Chapel in the church of the Annunciata, painted in oil in 1855. He has painted the Goodwin’s Christ disputing with the Doctors, and Christ driving the money-changers from the Temple. In the second he has introduced the portraits of Micheangelico and Giacomo da Pontorn to their own costume, besides several other portraits of his contemporaries in the character of dilettanti. He constantly introduced portraits of his friends into his historical pieces.

The son, Cristofano Allori, born at Florence in 1677, was a painter; and, as his father, he is said to have been a fastidious, and his works are scarce. In execution he was equal to anything, and he had (of course) a corresponding skill in copying. He is said to have made some copies of Correggio’s Magdalen, with slight alterations in the background, which now pass as duplicates by Correggio; he generally signed his own name on the back of the picture, but of this original work at Dresden; that which the Roman government recently forced Vallati, an animal painter, to return to its former owner, from whom he had purchased it in a disfigured state some months before for 15 scudi, may be one of these copies by Allori. It seems it had been carefully but badly painted over, probably during the French revolution, to preserve it. The fact was forgotten by or unknown to its present possessor, a few years ago, and he sold it as a picture of no value. Vallati, who bought it, discovered its identity, and paid £500 for it; but the Roman government has now recovered it to its original owner, who has since recovered the original work at Dresden, and is now valued at 5000l. sterling: the background differs slightly from that of the Dresden picture. Cristofano was an excellent landscape-painter. His masterpieces are considered the ‘Miracle of San Giuliano, in the Pitti gallery: San Manetto, in the church de’ Servi, and Holophemes; and a Magdalen, which was the portrait of his own mistress, a very beautiful woman. The Judith is also her portrait, and the Holophemes was painted from life. It is described as having been an important event that Cristofano became ‘reputed for the Venus Napoloni.’ He died in 1621: his portrait is likewise in the Florentine portrait gallery.

(Baldinucci, Notizie de’ Professori del Disegno, &c.; Landi, Storia dell’arte, &c.)

ALLOTMENT SYSTEM. The allotment system may be defined to be the cultivation of small portions of land by agricultural labourers and other classes of workmen at their leisure, and after they have performed their ordinary daily work. It is desirable that every smallholder should be entitled to the occupation of a certain allotment of land, and the right to cultivate his cottage for the growth of vegetables. In villages where the houses are not detached this cannot always be done, and the most convenient mode of giving them gardens is to divide a field near the village into small allotments. The allotment system is the most satisfactory mode of providing for the non-agricultural classes of the community of the town having ceased, to about the close of last century, and the bishop of Bath and Wells commenced the setting of allotments in 1807: but it is only since 1830 that its adoption has become common. In 1800 the agricultural labourers were in the habit of destroying thrashing-machines, and demanding higher wages; and at night the country was lighted up by incendiary fires.
Under the impulse of fear the farmers increased the wages of the labourers, but on the suppression of the disturbances they generally returned to the old rates. The season of alarms did not however pass away without some attempts being made to improve the lot of the labourer, and the extension of the allotment system was the most general mode by which an attempt was made to accomplish this object. A society, called the Labourers' Friend Society, was formed to promote the objects of the system, and to circulate information respecting it. Allotments (garden-allotments, or field-gardens, as they are sometimes termed) are now common in all the agricultural counties in England; but they are nowhere universal. In East Somerset there are to be found in the allotments, and the quarter of land devoted to allotments is said to be equal to the demand. At Farnley Tyas, Yorkshire, the tenantry of the Earl of Dartmouth have agreed to allot a road of land to the cottage of each labourer employed on their farms, the rent to be charged at the average rent of the farm, with the addition of rates and taxes.

In several of the northern and midland counties the allotment system is promoted, and in some degree superintended, by a society called the Northern and Midland Counties Ari- sans' Labourers' Friend Society. The number of acres under allotment, according to the report of this society, in June, 1844, was 1082. There are several similar societies in the market towns, and in the district in which his plot of ground was cultivated, and are not much differ from the social schemes of Mr. Owen. The Reddington Land Allotment and Provident Fund Society, in December, 1844, purchased forty-two acres of freehold land, on which it is intended to erect 160 five-fooled cottages, besides allotments for the use of the labourers. The allotments consist with the freehold of his cottage and garden, at the cost price. An industrial school is to be erected in the centre of the allotments. At Rotherham a Land Allotment Society has been established for the purpose of purchasing one road of land for each of its members by payments of seven pence a week. The society has already obtained possession of four and a half acres, which, in the last week of December, 1844, was divided into fourteen allotments and balloted for. The road of land that constitutes each allotment is to be let to the applicant, the object is to become proprietors of land. It is scarcely necessary to remark that the members of these societies are not agricultural labourers. Allotments are also found in the neighbourhood of several large towns, and the proprietors of factories have in many instances granted allotments to their workmen; but in both these cases the land is more frequently cultivated rather as a recreation than as a view of the means of subsistence. It has happened however, that in the Midland Counties landlords and farmers have employed in factories have been enabled to keep out of the workhouse with the aid of an allotment. At Nottingham land belonging to the corporation is divided into about 400 gardens, which are let to the tenant at a rent for the year of 1s. 3s. 4d. The greater number of these gardens have been cultivated for about 50 years. Where the tenant is an agricultural labourer, the main object is to increase his resources, and thus enable him to maintain himself without assistance from the poor's rate. There seems to be good authority for stating that the allotment system has been successful in this object; and that it has not only diminished the incentives to crime, but has encouraged habits of sobriety and industry, and led to a general improvement of character. Of the heads of families holding allotments of land in West Kent, not one was committed for any offence during the years 1841 and 1842. In the parish of Hallow, Kent, there were 35 commitments in 1835, and on the allotment system being introduced in the village of Ditton, commitments were reduced in 1837 to one, and from 1837 to 1843 there had been only one. About 15 of those who were committed in 1835 became holders of allotments, and up to June, 1843, no cause of complaint had arisen against any of them.

Of course it is not to be supposed that the administration of this system is perfect. Hence the tenants have not been able to obtain their allotments in the same manner as in the principal towns and cities; but it has been found that the landowners have been willing to grant allotments without the usual conditions of mortgage or lease, and that they are not always set at a rack-rent. Many persons recommend the landowner to take the cottages on each farm into his own hands, instead of allowing the farmer to let them. It is usual to let the land tenant to a tenant on his own responsibility for the rent, in order to save trouble, and to prevent the tenant being unexpectedly and frequently called upon for money.
payments. The rent of 137 acres belonging to Mrs. Davies Gilbert, divided into 419 allotments, is 428l. 8s. 54d., or nearly three guineas per acre, which includes rates, tithes, and the payment of the cost of improvements of houses and buildings, whose increase is paid for separately. The rents vary from 6s. up to 8l. an acre. The rent of 15 acres of land belonging to Mrs. Walker Ferrand, near Bingley, which are divided into 59 allotments, is 32l. 8s., or 1l. for each allotment, averaging as nearly as possible a rent of one guinea per acre. With the addition of rates and taxes, the cost of the 15 acres amounted to about 40l. per annum. The value of the crops for 1844 was estimated at between 400l. and 500l., or between 7l. and 8l. each. The tenants are chiefly employed in the worsted factories, and the form of agreement, which is usually signed by allotment tenants, embodies rules for the management of the land, and fixes other conditions for their observance. Spade-culture is invariably (except in the case of the prohibited) to underletting and working on Sunday. There are instances in which attendance at the parish church is enforced; and in other cases it is merely stipulated that there shall be attendance at some place of worship. The allotment is usually forfeited for non-payment of rent, gross misconduct, commitment for any crime, or wilful neglect of the land. Cottagers without families, those whose circumstances are considered tolerably comfortable, and those whose character is not good, are in some cases allowed to have a separate rotation of crops is sometimes required in the agreement. The growth of wheat is not allowed in some cases. Where it is encouraged, it may probably be safely assumed that in that particular district the labourer is worse off than usual. Some reckoning is made of the half-acre in one hand and the other half in potatoes; and it is assumed that other vegetables are grown in the garden attached to the labourer’s cottage. Captain Scobell thinks it unadvisable to exclude any one from holding an allotment on account of previous bad character, as there is a chance of his being reclaimed. Becoming permanently a pauper is a fit ground for exclusion; but when the tenant receives casual relief on account of sickness or accident, he is not excluded. So long as the tenant observes the conditions of his agreement, the landlord is not permitted to stipulate that he shall on no other account be ejected from his land.

There seems to be no doubt that the absolute produce of the soil when cultivated in small allotments is greater than the same land would produce under the ordinary course of tillage by farmers. A much larger quantity of manure is used; in some cases four times as much as farmers are enabled to put upon their land, and a single rod is frequently made to produce vegetables of excellent quality. The consumption of a labourer’s family for six months; but if every labourer had an allotment, the quantity of manure collected could not be so great as it is at present. The disposable produce per acre of land is of course much greater when the same quantity of land is divided into small holdings.

Captain Scobell estimates the average value of an allotment at 2s. per week, or about 5l. per year, and that during the year it is required. The rent, seed, and other expenses, it is said, will amount to 3l. 10s., leaving a profit (without deducting the cost of labour) of 15l. 10s., which is equal to 6s. a week for a whole year. Such an allotment as the above allowed to will require about 30 days’ labour in the course of a year; but it is necessary that the chief part of this labour should be given between Ladyday and Michaelmas. One of Mr. Sutton’s allotment tenants at Wigginton, near Tring, stated at the Michaelmas rent-day, 1844, that the total of potatoes, and of all the increase of vegetables, on an acre was between 6l. and 6l. Supposing that there are a million families in England and Wales who are in the same circumstances as the tenants of existing allotments, and that four times as much ground as is at present cultivated by allotments, 2,500,000 acres, or nearly 400,000 square miles, which is one-third more than the area of Middlesex, and about the 128th part of the area of England. This would be equal to about 43rd of all the arable land in England. At three guineas an acre, this would amount to 787,600l., and the value of the produce, according to Captain Scobell, would be about 5,000,000.

From the Anglo-Saxon period to the reign of Henry VII, nearly the entire population of England derived their subsistence immediately from the land. The great landed gentry consumed the produce of his demesne, which was cultivated partly by himself and his serfs and cottiers attached to the manor. These tenants occupied small farms, and paid their rent in kind or in services, or in both. The cottagers had each a small rent or parcel of land attached to his dwelling, and the right of turning out sheep and cattle, of cutting wood, and of gathering common woods, commons, and wastes of the manor. While working up the lord’s demesne, they generally received their food.

The occupation of the land by allotments in the form of 120 acres, and there is a discussion in existence which contains 21 distinct conveyances of the land, the soil has been traced at various dates between the years 1200 and 1400. During the thirteenth and fourteenth centuries, this farm, which is now occupied by one tenant, or there is some evidence of its existence which became the property of one owner, who let it as a farm to one occupier. (Quarterly Review, No. 81, p. 250.)

In the history of the parish of Hawsted in Suffolk, by Mr. T. Collinson, the cultivated land is called a cottager’s or labourer’s allotment land. The right of the occupant, which is a separate individual, to cultivate the land is called a “labourer’s allotment.” The same term is used of the right of some persons to cultivate the land, which was divided into small portions, or parcels of land, at a later period. The labourers, who cultivated the land, were also entitled to a portion of the produce, and by this means of cultivating the land, they became the property of one owner, who let it as a farm to one occupier.

The number of properties began to decrease; by the year 1520 it had been reduced to six; in the reign of James I. the six were reduced to two, and soon after this restoration, when the land became the property of one owner, who let it as a farm to one occupier. (Quarterly Review, No. 81, p. 250.)

The distribution of small farms in the sixteenth century, and the altered social state of the country which took place at that period, from a variety of causes, disserved to a great extent the labouring classes from the soil which they cultivated. They had produced previously for their own consumption, and as domestic manufactures were common, each household possessed within itself the means of satisfying its principal wants. They now more generally worked for money wages; and in some districts the legislature attempted to preserve them from dependence on this source of subsistence, by enacting penalties against building any cottage without laying four acres of land therefor. (51 Eliz. c. 7.)

There were on the farm of Captain Scobell more than 88 acres occupied in disbanding about one third of the tenants who could not be benefited by the local government. It was desired to secure that thecottager could turn a cow, a pig, a few sheep, or goose, and this right also gave him a portion of subsistence directly from the land. The division and enclosures of these cottages, which had been completed the process by which the labourer was thrown for his own dependence on the sale of wages. From the reign of George I. to the close of the reign of George III., about four thousand inclosure bills were passed. Under these allotments were made, not to the occupier, but to the owner of the cottage, and this compensation for the extinguished common right generally benefited only the large landholder; and when this was not the case, the cottage was tempted by a high price offered by his richer neighbour, and this was a step in the direction of the abuses of the old poor-law, to part with his patch of land.

So long as the labourer is paid fair wages, he can obtain the chief necessaries of life; yet it happens that in most parts of the country he would be unable to procure any other food when potatoes, which are but poor in his own consumption, though if potatoes for winter storing can be purchased from his employer, or grown under the usual conditions on a patch of his employer’s land, it will be as profitable as growing them himself, that is, if he is paid a certain price above the market. The necessity for cultivating the land on his own account, further than for the purpose of raising sufficient vegetables for his own consumption, and of looking to the allotment system as
great, that there is in small manufacturing establishments compared with large ones. Profitable production is carried on better on a large farm when proper capital is employed (and indeed a large farm without proper capital would ruin an owner), than if it were divided into a number of small farms and the same amount of capital was employed for it. It is obvious that the amount of fixed capital in buildings, agricultural instruments, and animals must be greater on the small farms than on the large one. There are many other considerations that show, as much as the climate, the economy, the large farms are best for the public, and consequently for the holders of such farms. The small farms, if stocked sufficiently, would pay the farmer, not equally well nor with large farms but they might easily well to make his investment profitable. But such farms are generally understocked. In fact it is only in those cases where the cultivation is with the spade, and the land is managed like a garden, that such small holdings can be made profitable: the holder cannot, as a general rule, enter into competition with the large producer as a supplier of the market.

In some countries, where there are numerous small landholders, and it is usual for the estate to be divided on the death of the head of the family, the tendency must be, and is, to carry this division further than is profitable either to the community or to individuals. But in such case the evil may correct itself: a man can sell what it is not profitable to retain, and sometimes it may be possible that the land has been long attached to a small plot as a tenant, and mainly or entirely depends on it for his subsistence, will not leave it till he is turned out.

The allotment system, when limited to the giving a labourer a small plot of garden-ground, presents many advantages. But the object of making such allotments is moral rather than economic: the cultivation of a few vegetables and flowers is a pleasing occupation, has a tendency to keep a man at home and from the public-house. In many cases also, a small plot of ground can be cultivated by the labour of the wife and the young children, and a pig may be kept on the produce of the garden. The agricultural labour of young children is very valuable but charitable labour cannot be employed on a small plot of ground. Such employment is better than allowing the children to do nothing at all and run about the lanes; and if their labour is well directed to a small garden, it cannot fail to be productive, and to add greatly to the supply of vegetables for the poor.

Any extension of the allotment system beyond what a labourer can cultivate easily at his leisure hours, or with the assistance of his family, may be for a time a specious benefit, but if carried too far it might be a temporary advantage to themselves and to the neighbourhood. But a continual extension of such allotments in the same neighbourhood, though it might be called for by the wants of the labourers, would be of no benefit to that neighbourhood. It involves sufficient capital, and the natural ends would be that many of them would be reduced to get their entire means of subsistence out of a small plot of ground. The allotment system then, if carried to this extent, involves the question of the advantage of very small farms as compared with large ones; a question that cannot be discussed satisfactorily without a consideration of the general economic condition of each particular country. But it may be laid down as a sure principle that in a country where a large part of the agricultural labour is employed in pursuits other than those of agriculture, the necessary supply of food and other agricultural produce, for those who are not agriculturists, cannot be raised so profitably in any way as by the system of large farms.

The system of allotment of land and the small farm system, on which the large part of the population in this country depends for their means of subsistence, will very probably continue for a long time. But it is, in the course of this distribution, have just as much as would raise produce enough for himself and his family; and ultimately, he must be content with less than is sufficient, and it would be reduced to the condition of the Irishman who lives on his own plot of land.

There is a difference between small farms of a few acres which are let on lease, and small farms which are a man's property. If all farms were divided into small holdings, there could be little accumulation and little improvement.

There is the same disadvantage in small farms compared with
to the advantage of letting such land 'at a fair rent, and in small portions, to industrious cottagers of good character.' The act is to be carried into effect by the trustees appointed by the Act of Inclosure, and by the parish officers in vestry assembly. The allotments are to be the fourth of an acre, and will not exceed an acre, and the rent is to be the average rent of land of similar quality in the neighbourhood. It must be let to industrious cottagers of good character, being day-labourers or journeymen, and not to be let by the holders of cottages. The tenants must cultivate their allotments in such a manner as to preserve it in a due state of fertility; and non-payment of rent or improper cultivation subjects them to be ejected. In case the land which the trustees are not able to let in a sufficiently profitable manner, it may be let, and other land for the cottagers may be hired. No habitation is allowed to be erected by the tenants.

The provisions of this act are extended to the acts 1 & 2 Wm. IV. c. 42 and c. 46, already noticed. The 5 & 6 Wm. IV. c. 69, § 4, places the working of the various acts quoted above under the control of the Poor Law Commissioners. In the session of 1844 a bill for the promoting the letting of allotments to the labouring poor was introduced into the House of Commons, which contained regulations and provisions for the superintendence of a very complicated nature. When a cottager has a garden attached to his dwelling, he may manage it as he pleases, and it may or may not be well cultivated, but his independence is not interfered with by the municipal or parish authorities. The bill in question, which is likely again to be brought forward, proposed to delegate the powers conferred upon parish officers by the acts already quoted to five 'wardens of field-gardens,' who were to be appointed by the local ratepayers for every meeting assembly, and who are to act in conjunction with the officiating minister of the parish. The wardens are to be authorised to take land belonging to the parish or to hire land to an extent not exceeding half an acre for every ratepayer assessed at not more than 10s. This land are they to let in field-gardens or small plots.

ALLSTON, WASHINGTON, a distinguished American historical and landscape painter, was born in South Carolina, in 1763. He was educated at Harvard College, which he entered in 1796, having spent a preparatory term, by the advice of his physicians, at Newport, Rhode Island. Having determined to follow painting as a profession, he resolved to visit England for that purpose; he accordingly set out in 1801, with another artist, for London, and 'entered the Royal Academy of Arts of London as a student, in which he remained three years, during the presidency of West.

In 1804 he went with a friend to Paris, and thence to Rome, where he remained two years. In the latter year he exhibited a considerable notice there by a picture of Jacob's Vision. He excelled chiefly in colouring, and is said to have created considerable sensation among the painters in Rome, by the peculiar and accomplished manner in which he treated asphaltum, after the manner of Rembrandt. Many of the German and Italian painters endeavoured to imitate his effects; they however failed, says the 'Morganbatt' (1807), and spoilt several of their pictures.

He painted several pictures at Rome, which were admired for their colour and chiaroscuro; among them a portrait of himself, and several landscapes.

In 1809 Allston returned to America, and at Boston married the sister of Dr. Channing. In 1813 he again visited England, where he obtained the 500 guinea prize from the British Institution for a picture of 'The Dead Man raised by Elisha's Bones,' which was afterwards bought by the Public Library of the Art Institute. In 1818 he was a member of the Royal Academy. In 1819 he received the following letter to his wife, at a time when he was himself in a very weak state of health. In 1814 he published a book entitled 'Hints to Young Practitioners in the Study of Landscape Painting.' In 1817 he paid a second visit to England, and he returned to America the following year, to America, to Cambridge in Massachusetts, where he resided until his death in July, 1843. He was an Associate of the Royal Academy of London; his election to which was owing to the high estimation in which he was held by his contemporaries. Fiorillo, in his history of painting in England, speaks of a clever picture by Allston, of a French soldier recounting his deeds of heroism to a circle of listeners around him. Two pictures of Jeremiah and Uriel are noticed in his Journal of Selected Artists, as having been painted by Allston in 1821. Shortly after his death a large unfinished picture of Balsamuz's feast by him was exhibited at Boston. He has left several other unfinished works. He is spoken of as having been a very accomplished man and an elegant writer.

(Act Union, 1843; Fiorillo, Geschichte der Malerei, v. v.)

ALOES—Medical Properties of. Though known to the ancients and largely used in modern times, the sources of this drug are not accurately determined. It seems better to follow the plan of the 'Edinburgh Pharmacopoeia,' and assign it to the families by which it is supposed to be produced. It is a thick, round, hard, and particular genus of plants, and is not at all difficult to distinguish, as done by the London Pharmacopoeia, to the A. spinata, which, though it may yield Socotorine and some Cape aloes, is not the source of Barbadoes aloes, which last would appear to be produced in Asia Minor, an plant very rare of Greece, and which furnished the aloes of the ancients, and which is now cultivated in the West Indies, as well as in Spain, Italy, and Sicily, from which latter countries France and other continental nations, but not Britain, are often supplied. This plan seems the more judicious, as the commercial varieties, however designated, or whensoever derived, are to be found of nearly every degree of excellence or worthlessness, if care be not taken in the mode of obtaining the article. Dr. O'Shaughnessy, whose position in the East gives him good opportunities of observing states, in his 'Bengal Dispensatory,' that 'the quality of the product is apparently more dependent on soil, climate, and preparation than on specific differences of the plant itself.' Not only has Barbadoes aloes become less valuable from changes in the mode of collection; but even the real Socotrine aloes has become deteriorated, from any person in the island of Socotea being at liberty to cut as many leaves of the now neglected plant as he pleases, and prepare it in any manner he may. When the real aloes was a very valuable commercial product, it was extensively used in Europe, not only as a medicine, but as a food. It 'Formerly every part of the island produced the aloe; and the whole was farmed out to different individuals, the produce being monopolised at a fixed price by the Sultan.' The boundaries however thus set up which consisted of loose stone walls, and were carried with immense labour over hill and dale, though they still remain, under the present unsettled government no longer distinguish property. The descendants of the owners to whom the several fields were formerly allotted have never been able to recover the aloe, therefore it has been forgotten. At present, any one collects the aloe leaves who chooses to take the trouble, and nothing is levied on account of the Sultan. (Lient. Welsted, 'Memoir on the Island of Socotea,' in Journal of Royal Geogr. Society, vol. v. p. 197.) In the language of the island the aloe is called Tayef; by the Arabs, Sooboth. Though this island possesses plants sufficient to yield nearly all the aloes required in commerce, very little is now obtained from it; and what passes under the name of aloes has been almost entirely attracted almost exclusively by the cultivation of the Aloe vera, the East Indian sort, as is rendered further evident by its being exported from Bombay. When one source of any article of commerce is dried up, it is the custom of the dealers to beget a new source, with a great advantage to the possessors; meaning, not that it is the produce of the place the name of which it bears, but that it possesses the qualities of the kind originally obtained from that part. Alterations in commerce, dependent on a variety of causes, are constantly rendering imperil its reliance on names a very unsafe guide.

Attention to the mode of extracting the juice might render aloe, whenever procured, of excellent quality; but it will be seen presently how little the ordinary methods are calculated to ensure this end, quantity rather than quality being aimed at by the preparers. The aloe, like the hyacinth and many other luscious plants, contains a vast quantity of a mucilaginous matter (vegetable albumen?), more abundant towards the centre of the thick fleshy leaves than near the surface. The mucilages of the aloe are altogether different from those contained in a distinct set of vessels (Ompangia, Link; Opophora, vasa laticiferis), which are distributed chiefly under the thick cuticle of the leaves. Out of these vessels the juice containing the mucilages is drawn out, and it is from these vessels that any foreign bodies or substances are carried to the aloe juice. The juice of the aloes of the Cape aloe, but it is quite distinct from that now spoken of.) It transverse but not deep incisions were made at various points and at proper distances in the course of the leaves while yet attached to the stem, much finer aloe could be procured by scraping off the juice from time to time as it flows, than by allowing it to become concrete and then picking it off. The general practice however is to cut off the leaves near the base, and put
their open ends into a skin, into which the juice flows. This is afterwards inspissated, either by spontaneous evaporation in the sun, or promoted by a gentle heat. When the leaves are sometimes made to assist the flow, but by this means 'large quantities of viscid mucilage are forced out, and mix with the proper bitter juice, which is proportionately deteriorated.' (O'Shaughnessy.) Dipping the leaves into hot water, by this preparation, heightens the action of the juice. When hygroscopicity is diminished, is equally objectionable, as the viscid mucilage then flows out more freely. Worst of all is the plan now, but not formerly, pursued in Barbadoes. Barbadoes is one of its effects of the oil. It is made by immersing for ten minutes in boiling water the chopped leaves previously enclosed in cloths or wicker baskets, increasing the strength of the decoction with repeated supplies of chopped leaves till the water is fully charged; then allowing the mixture to stand for 24 hours, finally evaporating the clear liquor with caution till it is concentrated sufficiently to become solid on cooling. The hot liquor is allowed to coagulate in large gourd-shells, in which it is always transported to Europe. (Christison.) From these different plans of collecting and inspissating the juice, results an article which differs considerably in appearance and greatly in value. Aloe is one of the few drugs in which adulteration is not extensively practised further than by substituting the inferior for the finer and more valuable. With properly prepared, sand and fragments of leaves and skins are frequently found in the samples.

A few of the most important sorts found in commerce may be enumerated: 1. The cost of true or natural aloe, as it is given, can scarcely be regarded as one of daily occurrence, and is noticed merely as a standard of excellence by which to judge of others according to the degrees in which they approach the standard. It is prepared by chopping a deep garnet-red colour, altered somewhat by exposure to the air; a coiled fracture, a resinous lustre, very translucent in thin layers, a beautiful garnet-red line by transmitted light, and a peculiarly fragrant odour. It is brittle, easily pulverizable, and of a fine golden-yellow tint when in powder. It is almost entirely soluble in spirit and the density of 1.050, a very scanty light flocculent matter being left. (Christison.) As specimens decline from this unusually high standard, the actual fracture becomes rougher, the colour less pleasant, the solubility less, they are not so readily pulverizable, the powder is of a deeper colour, inclining to brown, the residuum greater, and consisting of more of the flocculent matter, as well as incidental impurities. In regard to the amount of insoluble matter, Barbadoes aloe contains the most, varying from 5 to 12 per cent.; and it is much more difficult to reduce to powder, as the mode of obtaining it explains.

Varieties go by the name of —Socotrana; East Indian, called also frequently hepatica; and Cape aloe (Aloe tetracantha of Geiger and Theol. Martinus,) also called A. Cabo. Insoluble subvarieties of these are found. Caballine, or laevigata, has nearly disappeared from commerce, refinement or fashion in veterinary medicine deeming it not fit for horses.

Barbadoes aloe comes to this country in the gourds and calabashes into which it is poured when prepared. Each of these weighs from sixty to eighty pounds. When broken, the fracture is sometimes coiled, seldom lustrous, and having a more liver-like aspect, better entitling it to the designation of hepatica, by which it is frequently called, than any others.

The most critical chemical analyses of aloe have been made by continental chemists, and although they designate the species analysed, it cannot be accurately known how far they correspond with the kinds so called in Britain. The chief constancy is the presence of aloin, which is present sometimes to the amount of 81 per cent.; resin, varying from 25 to 50 per cent.; vegetable albumen, absent from the best kinds, present in others from 5 to 12 per cent.; gallotannin, present in eight to twelve per cent. of the aloe, according to Ferreira. Aloe is however of rather a more complex nature than appears from this view. Aloelin, or aloe-tannin, is entirely soluble in cold water, but not in absolute alcohol. When hot water is used, something is taken up, which is deposited as the water cools: to this the name of aloe-tannin has been given, perhaps not with perfect propriety. The aloelin is looked upon as the cathartic principle of aloe, rather than the irritant and objectionable ingredient. Hence in some of the 'Pharmacoceutica' an extract is ordered to accomplish their separation, a proceeding altogether unnecessary, when aloe of the best quality can be obtained by giving a proper price for it. The formation of a decoction by heat is still more objectionable, as a much superior preparation is made by cold water alone, more grateful to the stomach, and not less effective if given in larger doses.

Few more valuable drugs exist, as is proved by thenumerable subvarieties of aloes, as well as by the other articles combined with it. These combinations have various objects in view, some to heighten its powers, others to modify, and some to get rid of certain well-founded objections.

In large doses it is decidedly aperient, but is unlike many other cathartics in so far that increasing the dose beyond a certain point by no means increases the effect. This can be accomplished however by associating it with other cathartics, and still more decidedly by uniting it with astringents or iron or quina. Aloes and quina with antimonial powder, and aromatic powder to cover the unpleasant taste, form a combination of great utility in many gastrick derangements, especially where the head is implicated. When persons are so fortunate as to be rallying from the stage of collapse in Asiatic cholera, this combination given frequently improves the secretions and abates the fever. In some fevers with numerous liquid motions it may also be given with striking benefit, the motions lessen and disappear, the pulse becomes stronger and quicker, as well as becoming of a more healthy appearance.

The constitution of the bowels and brain which precedes water in the brain, aloes, either in this combination or in some other form, is of great utility. On the bowels, it is a sure means of increasing the power of the bowels, and of clearing the inspissated, or dried up stools, which has been frequently subject to a hemorrhoideal flux which has been suppressed.

The combination which increases the purgative power of aloes in the most remarkable degree is formed by adding one drop of strong (undiluted) sulphuric acid to four grains of Barbadoes aloe, and forming a pill, two of which, given every two hours, or six hours, will almost invariably produce the most of the most objectionable cases of constipation, such as occur in painters' cholie, ileus, and other diseases. It is even more efficacious than croton-oil, and so apt to excite inflammation of the intestines. This superior power is possessed of them, and with a general law, by which many vegetable principles have their properties heightened by adding an acid, either mineral or vegetable. Thus ammoniacum becomes a more powerful expectorant by adding dilute nitric acid to the mistsors ammoniaci; and the folic acid, such as ammobotul, are rendered more potent by solution in vinegar. (Acetum Anthystericum, formula No. 1, in Copland's 'Dictionary of Medicine.')

Aloe, especially the compound decoction, is a most valuable emmenagogue, particularly when combined with tincture of ergot or preparations of iron. From its action on the lower part of the bowels it is deemed an improper purgative in pregnancy or during the menstrual flux. It is also considered a dispensor for poison, and is ordered to be given when it is attempted to be obviated by various means, but the best way is to combine it with other agents, as stated by Dr. Christison, as many persons can take the compound gummo-poll, or compound extract of colocynth, who cannot take aloes alone. The best means of covering the unpleasant taste of aloes when given in the liquid form is the compound tincture of lavender.

ALPACA, or PACO. The natural history of this animal is treated of under ALPACA, A. P. C. P. The introduction of alpaca wool in manufactures has attracted considerable attention, and the question of naturalizing the alpaca in this country, in Germany, and in Australia, is also an object of much interest. The wool of the alpaca is superior to that of the Angora, and has a much longer staple. The weight of the alpaca averages from 10 to 12lbs, while that of our sheep is seldom more than 8lbs; and while the staple of English wool does not often exceed six inches in length, that of the alpaca varies from six to eight inches. The quality of the alpaca wool renders it applicable to many of the purposes for which silk is usually employed in textile fabrics; and it is found a useful substitute for Angora wool. The manufacturer of plain and figured stuff from the fleece of the alpaca was commenced first in Yorkshire, and the articles which were manufactured in this manner have been much admired. The consumption of alpaca wool in this country in the seven years ending December, 1843, is estimated by Mr. Walton at 12,000,000 lbs. A Parliamentary paper (197, Sess. 1844) gives the import...
of wool of the llama and alpaca tribe for the year 1843 at 1,485,032 lbs., and the consumption was probably higher in that year; for this wool is yet being produced in the Andes from 2s. to 2s. 6d. per lb. Towards the close of 1844 different articles were manufactured at Bradford for her Majesty, from the wool of an alpaca which had been kept at Windsor. The fleece weighed 164 lbs., and when sorted and combed 10 lbs., increased in value by the addition of a good deal of wool, the material being entirely jet black. One of the articles manufactured was an apron, in which the wool of the alpaca, without the admixture of any other wool, was used for the first time in this country; for, though large quantities have been woven at Bradford, it has usually been in fabrics where the warp was of cotton or some other material, and the weft only of alpaca. Amongst the other articles manufactured for her Majesty were a striped and figured dress; the warp consisting of roseline wool, and the weft of black and white plaid with figures on alternate grounds of alpaca and silk. This dress, which measured 12 yards, required 24 lbs. of alpaca. A plaid dress, measuring fifteen yards, and containing 24 lbs. of alpaca, was woven with an intermixture of silk and worsted. Another article was a plain black alpaca lustre dress, the warp of fine cotton twist, and the weft of alpaca. This required 24 lbs. of alpaca, and when taken from the loom it resembled silk from its impressing the same mark of its manufacture. Besides the use of the wool in textile fabrics, the fleece of the alpaca is also wholesome and palatable. The carcass weighs on an average about 180 lbs.

The question of naturalizing the alpaca has been taken up with some little pertinacity; but very little progress has yet been made in convincing the country of its practicability. The alpaca inhabits the mountainous and inhospitable regions of Peru, and is remarkable for its alophobia; but it has been domesticated and reared on the farms which have been brought to this country have been confined in parks and richly cultivated lands, and have been treated with too much care and tenderness. Mr. Walton asserts that they will live where our hardest sheep would starve, and that they will find as much food in Great Britain as in their native country.

In the Transactions of the Highland and Agricultural Society, 1844, there is an account, by Mr. Stirling, of the attempt which is now making to introduce the alpaca into Scotland. During the severe winter of 1843-4, when sheep required to be regularly fed with turnips and hay, the alpacas perseveringly sought their own food, and did not experience a single day’s illness. Mr. Stirling says that they were kept within enclosures better than sheep, and never attempted to leap a fence. In 1841 the Highland and Agricultural Society offered their gold medal for ‘a satisfactory account, founded on actual observation and experiment, of the attempt to naturalize the alpaca in Scotland;’ and in 1844 a prize was offered, at the same meeting, ‘for the best account of alpacas which have been naturalized and bred in Scotland, and the best two, male and female, imported. If, as Mr. Walton states, the alpaca may be pastured on lands which are now waste and unprofitable, and where the sheep would starve, the naturalization of the animal would undoubtedly prove a profitable object of enterprise;’ but if this is not the case, it is a question whether a constant demand for the wool as an article of import would not be quite as beneficial. The Peruvians would be induced to bestow greater care on the management of their flocks, and the possession of so valuable an export would bring them under influences of a civilizing nature, which would render them better customers for our commodities. The expense of introducing the animal is very great, and the long voyage kills more than two-thirds of the number shipped.

(Walton On the Alpaca; its Naturalization in the British Isles considered as a National Benefit.)

ALTDORFER, ALBRECHT, painter and engraver, a native of Regensburg in Bavaria, was born at Altдорfer in Bavaria, in 1488. This has been shown by Heinke, who acquired his information from a senator of Regensburg (Hatzliu), who found documents concerning the family of Alberti, which had a seat in Altдорfer in that city. Those who speak of him as a Swiss have been misled by Sandrart, who was the originator of the error.

Altdorfer was himself a member of the imperial senate of Regensburg, of which city he was an officer in 1511; he also archbishop of the city of Regensburg. He was probably the son of Ulrich Altdorfer, an artist of Regensburg, who gave up his right of burghership in 1491.

Altdorfer did not paint much, but his pictures show a surprising Residence and industry. There is in the Pinakothek at Munich a picture by him, representing Alexander’s battle of Arbela, of which the labour is prodigious. It bears the date 1529; it was perhaps ordered by way of war against the Turks, and is an innumerable mass of small figures, all in the German military costume of the day, every article of dress or military implement being made out with the greatest exactness; and all the various and probable incidents of a battle profusely introduced. One may almost fancy that this painting was not an attempt to represent actual incidents, but to imitate the whole of a historical picture which contains so many figures; the design is however strictly Gothic, and Altdorfer has wholly neglected the powerful aid of aerial perspective. This picture was formerly at Schlissel- burg, where it was burned to the ground. This picture was ordered by Holy Roman Emperor Charles V., at the request of the French king Robert Second, to be executed with the most accurate engravings, the engravings, the engraving of which would probably appeal multitudes to many engravers. His other pictures are in a similar style; he scarcely ever painted large figures: the Savoir with Mary and John, St. Peter, St. Catherine, and another saint, at the shrine of Molk, which are the only known exceptions, and these have been attributed to Albert Dürer, who is supposed by some to have been the master of Altdorfer, but it is a mere conjecture.
contemporary. Mariotti however, in his 'Lettere Pittoriche Pergino,' states that Alunno was established as a painter at Foligno as early as 1460, and that he painted at least two years before that date. He was a native of Foligno, and his workshop was in Assisi, the city of Nicolò Fi- 
giato Opus; but there was a Niccolo Deliberatore, likewise of Foligno, and therefore all the works with this signature may not be by Alunno.

His father, Alunno lands in a chapel of the Assisi of which there is now scarcely a trace left; Vasari speaks of a Pietà as a part, with two angels bearing torches, and weeping so naturally, that in his opinion no painter could have done them much better. Besides which Vasari mentions a painting by his father of the Virgin and Child in a frame of Saint Agostino, at Foligno; an alter-piece for San Francesc, and another for the high altar of the cathedral of Assisi. There is still at Foligno, over a side altar of the church of San Pietro in Montorio, a fresco painting which was attributed to Alunno in 1492: it had formerly a predella, or a long picture in various compartments, which served it originally as a base, according to the old Italian custom with altar-pieces; but being one of the paintings which the French thought fit to send to Paris, it was returned at the general restoration of the plundered works of art, without its predella, which is now in the gallery of the Louvre. It contains six pictures, one of which is an allegory of the history of its works, and was written some verses which are legible with difficulty, celebrating the abilities of Alunno, and the generosity of a lady of the name of Bressola. The other five pictures are from the life of Christ. They are drawn in a dry and meager style, they have very broad outlines, and very contrasting lights; but they have much expression, and are executed with facility. Alunno excelled in expression; he was in the habit, in his large pictures, of painting the heads from the life, which gave them a truth and reality not found in the works of many of his contemporaries. The period of his death is not known, but he painted after 1600; he painted in the old manner in water-colours, or a tempura. Alunno painted his own portraits, and religious pictures which are called gonfalone. There is still with a gonfalone of this inscription by him made of very fine canvas, in the church of Santa Maria Nuova, at Perugia, with the inscription—
'Societas Annunciate fecit fieri hoc opus, 1466.'

(Vasari. Vite de' Pittori, etc.; Landi, Storia Pittorica, etc.; Rumoh, Italienische Forschungen.)

ALVAREZ, DON JOSE', a very distinguished Spanish sculptor and one of the most eminent artists of the nineteenth century, was born at Priego, in the province of Jaén, in 1798. His father, Jeronymo Alvarez, was a sculptor, whose youth was spent as a labourer in that business, as his father was too poor to send him to school. However, in 1825, a public competition for the best sculptor was held, and Alvarez was awarded the first prize. In 1826, he was elected a member of the Royal Academy of Fine Arts, and in 1827 he was appointed professor of sculpture at the School of Fine Arts in Madrid. Alvarez excelled in every branch of sculpture, and his work was recognized throughout the country. He was especially noted for his portraits and busts, which were considered the best in Spain. In 1848, he was appointed professor of sculpture at the Royal Academy of Fine Arts, and in 1850, he was elected a member of the Royal Academy of Fine Arts. He was also a member of the Royal Academy of Sciences, Fine Arts, and History, and the Royal Society of Sciences.

ALVILLOTES (Lamarck), a genus of fossil Polypriaria, from the cretaceous and tertiary strata.

AMALTEO, POMPEIO, a distinguished painter of the Neapolitan school, born at San Vito in the Frati, in 1505. He was the son of Giovanni, who had painted in the style of that master, though he was less bold in execution and inferior to him in invention. His Three Judgments however, in the court of justice or loggia at Ceneda, which were completed in 1536, were long supposed to be by Pordenone, both through their style and the mistatement of Ridolfi. They are the Judgment of Solomon, the Judgment of Daniel, and a Judgment of Trajan, and are considered Amalteo's masterpieces.

Vasari, in the Life of Pordenone, some frescoes by Amalteo in the Castle of San Vito, for which he was ennobled by Cardinal Grimani, the signor of San Vito, and patriarch of

of the value of 500 francs. Notwithstanding this personal honour, Napoleon's after-conduct regarding Spain excited in Alvarez an irrevocable aversion to him: he would never model his bust; and when Joseph Bonaparte was proclaimed king of Spain in 1808, he left Italy, and entered the castle of St. Angelo for refusing, as a pensioner of the Spanish government, to take the oath of allegiance to the new king; he was however released shortly afterwards. After the completion of his statue of Ferdinand VII, Alvarez's pension was increased to 28,000 reals, and he left Paris for Rome, where he hence forth chiefly resided. In Rome he executed or modelled many much admired works, the best of which was a group of Amlothous and Memnon in 1818, for which he was nominated Knight of the Order of St. Louis. He commissioned him to execute the group in marble: it is now in Madrid.

In 1825 he was appointed principal sculptor to the King of Spain, and was decorated with the cross of Civil Merit. In 1836 he visited Rome with the purpose of selecting the best statues and other sculptures in the king's palaces to be placed together in the museum of the Prado; but he died within twelve months of his arrival, in the sixteenth year of his age. From his office, the circumstances connected with his death, and the honourable commission about which he was engaged, it is evident that the reports which appeared in the French newspapers at the time of his death about his extreme poverty bordering upon destitution must be false. There are no facts to support the extreme poverty which is hinted in some of his letters; for during his long residence in Spain, he was possessed of a large fortune, and the best of his works were executed for the favourite Guzman; of whom he was appointed principal sculptor to the King of Spain, and given the commission to execute the group in marble: it is now in Madrid.

It is generally admitted that Alvarez excelled in many qualities of a high order, in invention, in expression, and in design; and he is by his admirers compared with Canova. That he is less generally known than many of his more for- tunate or more renowned contemporaries, is probably more owing to an ignorance of his works than to their inferiority. He was a member of the Institute of France, the Academy of St. Luke of Madrid, and of the academies of Carrara and Naples. He left behind him a large and valuable portion of their father's pension. The eldest, who promised to be a sculptor of ability, died at Burgos in 1830, in his twenty-fifth year.

There was another distinguished Spanish sculptor of this name, Don Manuel Alvarez, who was born at Salamanca in 1727. After acquiring the rudiments of his art with two sculptors of Salamanca, he repaired to Madrid, and became a member of the Royal Academy of Fine Arts, the first sculptor, whom he assisted in many of his works. He obtained the prize of the academy of San Fernando in 1754, by which he was entitled to study in Rome, with a pension from the Spanish government, but he declined the advantage on account of the weakness of his health and the disapprobation of his father. He was elected a member, in 1762 vice-director, in 1786 director of the academy of San Fernando; and in 1794 sculptor to the king. He died in 1797, generally regretted, in the seventieth year of his age. His busts and vases are very numerous in the churches, palaces, and monasteries of Spain, especially at Salamanca, Toledo, Zaragoza, and Madrid. Alvarez was commonly called by his fellow-artist El Greico, or the Greek, on account of the purity and vigour of his design, and his accuracy of execution—a great compliment.

(Archivo für Geschichte, etc., 1829, No. 15; Seminario Pintoresco Español, No. 62; Cezar Bermudez, Diccionario Historico de las Ilustres Profesores de las Bellas Artes en España.)

ALVEOLITES (Lamarck), a genus of fossil Polypriaria, from the cretaceous and tertiary strata.
Aqulca. Amalteo was distinguished for good drawing, a quality rare among the Venetian painters.

Pompion's brother and pupil, GIROLAMO, had also great ability for painting, but he generally painted small pictures, his best being those of the Madonnas. Otherwise, says old writer, he would have rivaled Pordenone in reputation. By which observation we may infer, with Lanzi, that the story told by Ridolfi about his being induced to give up painting and to study law, through a promise of an allowance of 100 ducats per annum from Pompion, is not true. The meaning of the story is, that Pompion was jealous of his brother. It seems that such a transaction did take place between Titian and his brother. Amalteo was a great practitioner of the latter art, and was numerous in Italy about the district of Friuli, but he was unequal: many of his pieces have very little merit. He had several scholars, some of whom distinguished themselves. One of his pupils, Giocoferto Moreto, made a good painter at Quintilla, who likewise painted and executed some works in sculpture. The date of Pompion's death is not known, but it was probably prior to 1588, according to the following inscription upon a picture at San Vito, in Inchiostro, Pompionus Amalteus, perfect Joseph. Mortius, A. 1588.

(Altan, Memorie interno alla Vita di Pompionio Amalteo, in the Opuscoli Cologeriani, vol. xliii.; Renaldis, Della Pittura Friulana; Lanzi, Storia Pittorica, &c.)

AMALTO, ANTONIO D', a distinguished painter of the early half of the sixteenth century, and one of the best of the Neapolitan painters, was born at Naples in 1475. There is not much that has been related himself chiefly by studying the works of Maestro Bertrami, to whom he was taught all that he had, and whom he served at Naples in 1485, and an altar-piece of Pietro Perugino, which is in the Cathedral of Naples.

Amato was a remarkably pious man, and probably respected by the clergy for the fidelity he had shown in the picture of the Madonna and Bambino, his most favourite subject, without first taking the sacrament, and thus purifying himself for the holy use. He carried his feeling of propriety so far as to consider it wrong even to show a naked woman; and insomuch with this feeling he refused to paint the decorations of the triumphal arch which was erected in honour of Charles V. when he visited Naples: he recommended Andra de Salene to the authorities in his place.

The painter he lived chiefly in the sixteenth century, his style is more that of the quadracoastitis, and is very similar to that of Perugino, but, with equally good colouring, the forms of Amato are fuller than those of Perugino. He painted in oil and in fresco, but his frescoes have almost all disappeared: they have either been whitewashed or have disappeared in the repairing of their localities. His best picture is considered to be the Dispute on the Sacrament, in the Cathedral of Naples.

Amato's numerous scholars, his own nephew of the same name, born in 1555, was one of the most distinguished. He was called II Giovane, to distinguish him from his uncle, who however was himself sometimes called II Vecchio, or the Elder. The nephew after the death of his uncle was called theNephew of the Elder Amato. His best work is a large and admirable altarpiece of the Infant Christ, in the church of the Banca dc' Poveri at Naples: he was a beautiful colourist. He died at Naples in 1590.

(Dominici, Vita de' Pittori, &c. Neapolitani.)

AMBERGER, CHRISTOPH, a celebrated old German painter of the sixteenth century, was of a family of Amberg in the Ober Pfalz, whose name; but Amberger himself was, according to Giorgi Bernoldi, an older scholar of the elder Amato. His best work is a large and admirable altarpiece of the Infant Christ, in the church of the Banca dc' Poveri at Naples: he was a beautiful colourist. He died at Naples in 1530.

(Dominici, Vita de' Pittori, &c. Neapolitani.)

Amberger painted also in oil and in fresco. His oil pictures are chiefly portraits, much in the style of Holbein, whose portraits he studied and copied. Fiorillo states that many of Amberger's copies pass as the originals of Holbein. He is himself a painter of history, and executed in the hard manner and sharp Gothic style of the period in Germany, without any feeling for aerial perspective, though the rules of linear perspective were well observed in his works: his compositions are well wrought with the utmost care. He has painted in his time portraits of Charles the Fifth, Charles the Ninth, and Charles the Second, King of France, and Portraits of the Emperors Maximilian and Charles V., and Portrait of a Lady, with landscape, in the Museum of the picture gallery of Berlin, and according to the inscription upon it was painted in Charles's thirty-second year, or in 1632. Sandrart speaks of a portrait which was painted in 1530; but from the fact that Charles the Fifth went in the year 1537 to Pavia, Bologna, he showed himself to be painted again so soon, and Sandrart's date may be wrong, and the portrait he speaks of may be that in the Berlin gallery painted in 1532. However, about the portrait

(Nagler, Künstler-Lexicon; Conversation-Lexicon für Bildende Kunst.)
of which he speaks, he says that Charles expressed himself highly satisfied with it, ordered thirty-six rix-dollars, three times what Amberger asked, to be paid to him, gave him a cold chain and medal, and said that it was as good a picture as the one Holian had made of it, which had cost him one hundred rix-dollars.

Amberger is generally supposed to have died about 1563 at Augsburg: he was however still living in 1568 according to some judicial records in that place. As in type 3 is often mentioned the date 1563 of earth, some scholars may be led to conclude that 1563 may have originated in a misprint of 1568, which was probably the year of his death.

(Sandurt, Zeitschrift, etc.; Michel, Catalogue des Tableaux, etc.; Künstlerischen Sammlung zu Berlin: Nagler, Künstler-Lexikon.)

AMBLYPTERUS (Agassiz), a genus of fossil Ganoid fishes, from the coal formation of Edinburgh.

AMBLYSEMIUS (Agassiz), a fossil fish, from the sediments of Somersettshire.

AMERICAN ANTIQUITIES. At the commencement of the present century the existence of antiques in America was hardly known in Europe, if we except those in the vicinity of the town of Mexico, and at a few places in the Andes of South America. But since that time we have become acquainted with such a number of ancient monuments, that not only Europe, but nearly every part of the globe, except Spain and Africa, have been opened to unlimited investigation, and these parts of North America where antiques exist have only been discovered by the eye of the American.

In the last-mentioned countries the monuments of the ancient population are generally overgrown with forests, which concealed their existence until the country was fully explored.

The North American antiques are of two descriptions: they are either fortifications or mounds. The fortifications are not found to the east of the Appalachian Mountains; but on the west of them they occur in many places. The most remarkable is that of the Basket Rock, which falls into Lake Ontario at its eastern extremity; but here, as well as in the Genessee county and other parts of New York they are small and difficult to trace. Further west two extensive systems of fortifications may be traced. One extends over the southern portion of the state of Ohio, and is enclosed on the east by the course of the river Muskingum, and on the west by the Miami. The most northern fortifications extend into the county of Lieking, to the vicinity of the place where the Miami and Great Black river, which falls into Lake Erie, unite. These fortifications have four forts, enclosing from twenty to forty acres each, and consisting of earthen walls from eight to thirty feet high. Two of these forts are perfect circles, one a perfect square, and the fourth is an octagon. These forts are severally connected by roads as far as thirty miles long, which are divided by similar roads with some creeks. Other less extensive fortifications are in Perry county, but those near Marietta, near the confluence of the Ohio and Muskingum, occupy a considerable space. These are the ancient fortifications in the valley of the Muskingum.

In the valley of the Selot a square fort with eight gateways is united to a circular fort surrounded by two walls and a deep ditch between them. The town of Ogdensville, in the county of Ficksayar, is partly built in the circular fort. Extensive works of a similar kind exist on the Paint Creek in the county of Ross, west of Chillicothe; and others at the confluence of the Selot river and the Ohio, near Portsmouth. There are several isolated fortifications to the east of the Little Miami river, and in the country between this river and the Great Miami.

The other system of fortifications occurs on the banks of the Mississippi, but we are not so well acquainted with the locality. There are several forts in the vicinity of St. Louis, one of which extends a long distance toward the south, about a quarter of a mile from the river.

The square forts, like the pyramids of Mexico, face the cardinal points. When they have only one entrance, it looks toward the east. The walls are usually made of earth, but there are also one or two instances where they are of stone.

To convey a more precise idea of their construction and disposition, we shall give an account of the works near Marietta. They consist of several walls and mounds of earth, in direct lines, and in square and circular forms. The largest square fort contains 40 acres, encompassed by a earthen wall from 20 to 30 feet high, and from 30 to 80 feet broad at the base. On each side are three openings, at equal distances, resembling 12 gateways. The entrances at the middle are the largest, particularly on the side next to the Muskingum. In front of this gateway is a covered way, formed of two parallel lines of earth, 48 feet broad. The side nearest the Muskingum the most elevated part on the inside are 21 feet in height, and 42 in width at the base, but on the outside they average only about 5 feet in height. This covered way forms a passage of about 200 rods in length, and 4 rods in breadth, passing over low grounds, where at the time of its construction it probably reached the river. The walls commence 60 feet from the ramparts of the fort, and increase in elevation as the way descends to the river, and the bottom is rounded in the centre in the manner of a well-formed turmunk.-Other mounds in front of the fort are three square mounds. One at the north-west corner is an oblong square, 190 feet long, 132 feet broad, and 9 feet high, level at the summit, and even now nearly perpendicular at the sides. Another elevated square is 150 by 120 feet, and 8 feet high, and similar to the other, except that of instead of an ascent to go up by on the side next the wall, there is a hollow way 10 feet wide leading 20 feet towards the centre, and then rising with a gradual slope to the top. The third square mound is 100 by 50, and 20 feet high, at the ends 10 feet wide, but it is not so high as the others.

At a short distance to the south-east is another smaller fort, containing 20 acres, with a gateway in the centre of each side, near which are two other mounds, and in front of these mounds in front of them, either within or without the enclosure. Still farther to the south-east is a mound in the form of a sugar-loaf. Its base is a regular circle 150 feet in diameter and 21 rods in circumference. Its altitude is 30 feet. It is surrounded by a ditch from 5 to 10 feet deep, protected by a parapet four feet high, through which is a gateway towards the fort 20 feet in width.

These fortifications are peculiar to the plains drained by Ohio and Miami; there are no others near the Indian tribes. These mounds are similar works found. Mounds or tumuli however occur in many other countries of Europe and Asia. In the countries bordering on Lake Erie they are of inferior size and fewer in number than in those which lie nearer the banks of the Ohio. It is believed that these mounds exist all over the countries between the Appalachian range and the Rocky Mountains, and as far south as the Gulf of Mexico. They vary greatly in their dimensions. Some are only four or five feet high and ten or twelve in circumference, whilst others have 100 feet in diameter, and 40, 50, 80, 90; and some more than 100 feet, and cover many acres. Their base is round or oval, and their shape that of a cone, but sometimes flat at the top. They are made either of stone or of earth. Many of them are in the vicinity of, and sometimes within the towns and villages. It is certain that of some that thus situated have been used as stations to discover the approach of an enemy. But it is evident that the greater number of them are sepulchral monuments. In most of the lower ones great numbers of bones have been found. In the more elevated tumuli only a skeleton or two have been found. In the monuments of the last description, some utensils and trinkets are usually found, as hatchets made of stone, vases of earthenware, vases and ornaments of copper, a little iron sometimes, and sometimes fragments of earthenware, plated, and very rarely a little gold. One of the larger of these tumuli is found on the banks of the Ohio, 12 miles below the town of Wheeling in Virginia. Its figure is a truncated cone, measuring 280 feet in the East and 210 in the West, and 180 feet in perpendicular height. The height appears to have been originally greater, and the form more regular. This mound was opened in 1839, and there were found in the centre two cavities, one towards the base and the other towards the top. In the lower cave were several vases, and in the upper one in a state of position, but nothing else. In the upper cavity was a single skeleton and along with it 1700 ivory beads, 500 small shell-sheaths of the value class; 66 pieces of mica, each of which contained four perforations, and an arrow-head, a flint hatchet, and five copper bracelets or arm-bands, but without being soldered at the points of junction. None of these relics evinced any artistic talent or acquirements beyond what are possessed by every Indian on the frontier. But there was also found in this mound a small elliptical stone table, with 24 distinct characters arranged in parallel lines. It appears
that they are not letters, but hieroglyphics. Some very high tumuli are found in the neighbourhood of St. Louis, and among them are a number of large pyramids, which are considered as important in an historical point of view, as they seem to connect the antiquities and consequently also the civilization of the ancient tribes that inhabited the United States with those of Mexico; for these tumuli appear to be the remains of the teocallis of the Spaniards.

We pass to the Mexican antiquities. On the river Gila, which falls into the Rio Colorado, some large ruins are said to exist under the name of Casas Grandes. Humboldt considers these as early as the first temple of the Aztecs, and that they were the remains of the migrations from the north to the south, and he has given some account of them and the surrounding population according to the information published by two monks in 1792. These ruins have not been found since. It is true that nobody has ever seen them, but the country in which they are supposed to have existed has been traversed by several persons, who do not mention the high civilization of the Indian tribes inhabiting these regions. It appears that the country is uninhabited, and that being the case, ruins may escape the attention of travelers for a long time. But there are Casas Grandes in the state of Chihuahua between 30° and 31° N. lat., where for several leagues the country is covered with the ruins of buildings, among which some edifices of a very considerable size are included. The ruins of ancient edifices are evident in many other parts of the United States, and it is not improbable that, if the site of each ruin could be accurately surveyed, a monument of a great extent, if not of the whole, might be discovered.

The ancient monuments of Mexico, in this respect, differ very much from those of the Old World. Indeed, Humboldt finds a resemblance between the Mexican teocallis and some of the pyramids of Sakkara in Egypt. But there are also ruins of buildings, which evidently have not been very different from those of the Aztecs, and which appear to have been erected at a period when Humboldt visited America only one group of ruins of this description appears to have been found in Mexico, at Mitla or Mijuatlan, south-east of Oaxaca, which the author of his "Vues de l'Amérique centrale" describes as a place surrounded by ruins of a large building, 386 feet high, which has been surrounded by a ditch, and divided by the work of man into five stages or terraces, which are covered with mosaic. The whole forms a truncated pyramid, whose four sides exactly front the four cardinal points. On the top of the hill is a flat space, containing more than 12 acres, on which there are the ruins of a small building, which may have been a kind of watch-house.

The antiquities of Meso-America are of a different character, and very much resemble those of the Old World. The Teotihuacán race, whose ancient city is situated at a few miles from Mexico, has built temples and palaces of gigantic dimensions, and which are not inferior in size to the largest in Egypt or Asia. The Pyramid of the Sun is 205 feet high, and that of the Moon, 138 feet high; and both are surrounded by an area of 69 acres. The step-pyramid of CholulaJimenez or Zeki has been built by the Aztecs, and is the largest of those described by Humboldt. It is built around a hollow square, and is 200 feet long on each side. It has four stories, of 20 feet, 30 feet, 100 feet, and 50 feet high, and it is situated in a most picturesque situation.

To every one who has been on a vantage point, the view of the great Pyramid of the Sun, and of the whole of the city of Mexico, with the other ancient monuments, is one of the most sublime and magnificent which the eye is capable of admiring. There is nothing in human art which can equal the grandeur of those works, which were erected in a period when the sciences and arts were at a very low state. The monuments of the old Egyptians, for instance, are of a more elevated and sublime kind of art, but they are less considerable in numbers, and in extent.

upon which the inhabitants had acquired was certainly such as to imply the existence of several mechanical arts and trades, but it is not easy to comprehend how any article could have been required to such an extent as to constitute a regular branch of manufacturing industry. The state of society therefore did not require towns; nor did the account of commerce nor for the establishment of manufactures, and yet we find it stated that the number of towns is great. It is evident that for the government of the country a single town would have been sufficient. We may therefore presume that these ruins are the remains of towns; and of what kind of buildings they are the remains is very difficult to ascertain, as we are entirely unacquainted with the state of society in those countries when those structures were erected.

The three high pyramids, the top of the whole being a large square, constituted the main part of the front wall. The front of these buildings is generally ornamented with numerous sculptures. This edifice is evidently the principal object in every group of ruins. It is surrounded by some ancient temples once occupied, or at least not occupied. Among these outbuildings, as it were, sometimes an edifice is found which, according to our ideas, may have been a temple; but nothing has been produced which proves them to have been places of public worship. Generally there is one, and sometimes two temples, connected with the bulk of the ruins, but even their use is uncertain. As the ruins are not found in places where there are many of the town, we are inclined to think that they were the residences of a ruling priest-bishop, for the political constitution has been founded on theocratical principles. But perhaps they have been baronial establishments. It is known that the political constitution of Mexico rested chiefly on feudal principles, and that the bulk of the nation were bound to give a considerable part of their time and labour for the advantage of an hereditary nobility. We may therefore presume that this was also the case in Yucatan; and such a state of society appears to have been much favoured by the peculiar character of the country, there being water for irrigating the fields, which can only be obtained at the expense of great labour. [YUCATAN, P. C. P. 722.]

The most famous of these ruins are those of the city of Palenque, as it is called, which lies near the boundary-line between Mexico and Guatemala. The whole of the town was covered in the middle of the eighteenth century, and from that time it has been always stated that they cover a space of six leagues in circumference, and contain public works of great magnificence. We now know that the ruins consist only of a large building called the Palace, and four or five other buildings of inferior size, in a tolerable state of preservation, with the remains of a few others so utterly dilapidated that it is impossible to say what they have been. The palace stands on an artificial foundation of earth and stone, which has remained without injury for about two thousand feet in front and rear, and 260 feet on each side. The palace itself stands with its face to the east, and measures 528 feet in front by 180 feet deep. The height is not more than 26 feet, and consists of three stories. The principal building is a tower, or court-yard.

There are no windows. The front contains 14 openings resembling gates, each about nine feet wide, and the intervening piers are between six and seven feet wide. The building is ornamented with stone, with a mortar of lime and sand, and the whole front is thrown over with a painted coating. The piers are ornamented with spirited figures in bas-relief, but only six of them remain. The outer walls of the palace, as it were, are formed by two parallel corridors running north and south and connecting a large open court on the east side. The floors are of cement, as hard as the best in the remains of Roman baths and cisterns. The space enclosed by these corridors contains four court-yards, separated from one another by corridors of less extent, several sets of apartments, but connected again by passages between the corridors and rooms. The number of the apartments exceeds 90. The bas-reliefs in stone and in stone, in the court-yards of the palace, attract attention partly on account of the manner in which they are executed, and partly on account of the style of the figures. In one of the court-yards is a tower whose base is 80 feet square, but it has three stories, and is conspicuous for its height and proportions. Nearly contiguous to this great palace is one of inferior dimensions. It stands on a pyramidal structure 110 feet high on the slope. This building is 76 feet in front and 20 feet deep. It has five doors and six piers, all standing. The piers, without exception, are octagonal, and the corner piers are covered with hieroglyphics, each of which contains 96 squares. Besides these two tablets, there are in the corridors of the interior three others, likewise covered with architectural designs. Two or three buildings of this kind are remarkable, but they also contain a few bas-reliefs of value. All these buildings stand on the top of artificial mounds resembling pyramids, and the slopes of these mounds have evidently been faced with stone, which however has been thrown down by the growth of the trees which now cover them.

The ruins of Santa Cruz del Quiché are connected with the conquest of this part of the country by the Spaniards, and are therefore the only remains which have an historical value. These ruins are situated on the north-western extremity of the peninsula of Yucatan. These ruins are far from being extensive, and very little remains of the work erected by them. The natives before the arrival of the Spaniards, for the purpose of rendering this place impracticable. These ruins are on a hill nearly 100 feet square at the summit, and are surrounded by extensive ruins. A part of one of the ravines is stated to have been made by the natives; and it is said that upon it 40,000 men had been employed at one time. The flat top of the hill is surrounded on the south by the ruins of the pyramid, and on the north by the ruins of the governor’s palace, and on the east and west by the ruins of the other parts of the town. The ruins of Palenque are very richly adorned, and the city was remarkable for its many temples and churches. The ruins of the palace were long supposed to be the work of the Aztecs, but recent discoveries prove that they were the work of the Toltecs, who, it is stated, the Toltecs had attained a higher degree of civilization than the Aztecs, and the ruins of their buildings appear to confirm this opinion. It is however problematical if the ruins found east of the isthmus of Chiquimula belong to the same people, as they are distinguished from all other American antiquities by very marked characteristics. The most extensive of these ruins, and certainly the most remarkable, are those of the city of Copan, which are on the north-western side of the river Motagua from the south. This city was in existence at the time of the arrival of the Spanish, and was destroyed by them on account of an insurrection, which happened among the natives some years after they had submitted to the conquerors. At some distance from the ruins of the town, and opposite to them, is the ruins, and the whole site of the town is overgrown with large trees and underwood. The ruins are dispersed over a space about a thousand feet in length and five hundred in width, and consist of the remains of strong and high walls constructed of massive hewn stones, and of several pyramidal buildings, but there are some square altars, of which one is sculptured on the four sides and the top, and of a considerable number of stone idols, most of them still standing, though a large number have been broken or destroyed by the Spaniards. These sculptures, on the best preserved of these altars is in bas-relief, and this is the only specimen of that kind of sculpture found at Copan, all the rest being in bold alto-rilievo. It is six feet square and 10 feet high, and the top is covered with hieroglyphics. The sides of this altar are covered with sculptures representing each four human figures in sitting attitudes. There are perhaps no ruins which show greater art and ingenuity and more labour than the ruins of Copan, and they may in these respects be compared with the temples
of Elephants and Elefants in Hindustan. It appears that other ruins of a similar description occur in this part of Central America. We know at least that some idols of stone are found at a place called Quirigua, which is situated on the banks of the river Motagua, several miles east of Encuentros, which runs along the western side of the great road leading from the port of Yatoco to the town of Guatema. The idols are exactly in the same style as those of Calapa, but they are two or three times as high. At this place is also found an obelisk, or rather a curved stone, twenty-six feet high, and probably twenty-eight feet in circumference. These sides represent figures of men, and are finely sculptured.

It is probable that other ruins will be found in the states of Honduras and Nicaragua, as these countries too, at the time of the conquest, were inhabited by the ancient Spaniards by tribes which had scarcely emerged from the lowest state of civilization. No ancient monuments are met with in the republics of Venezuela and New Granada, though it is probable that these nations inhabiting the table-land of Cundinamarca, or of Bogotó, have made considerable progress in civilization. There are however a few ancient edifices in Ecuador, on the table-land of Quito. Not far from the volcano of Cotopaxi are the ruins of a large building called the Temple of the Sun. It consists of three stories, each side about thirty yards, and it has four doors. The interior is divided into eight apartments, three of which are still in tolerable preservation. Not far from the mountain-pass of Ayacucho is what is called the Fortress of Caziar, a building consisting of three walls, of stones, about five or six yards high. It has an oval form, of which the greatest axis is nearly forty feet long. A modern traveller mentions an ancient fortress called Huilcay, situated not far from the town of Ayacucho, which evidently belonged to some ancient and important state, but which is rapidly going to decay. The ancient Peruvian monuments are not, like those of Central America, distinguished by sculpture and rich ornaments, but by solidity and simplicity, as is proved by the great road of the Incas, running from Quito to Cuzco and farther southward, and by the massive stone buildings which are dispersed over the mountains of the Andes. There are however the ruins of some destroyed towns in the coast of Peru, and the Pacific is a state that no traveller has thought it worth his while to give us a description of them. Neither in Brazil nor in Paraguay and the states of the Plata have ancient monuments been discovered.

This short and rapid survey of American Antiquities is incomplete. Such as it is, it shows the immense extent of country over which they are dispersed, and gives a slight indication of the great difference in character which they exhibit. This difference must be an additional stimulus to investigate their origin and use, to all those who take an interest in the history of the human race; but the study of American Antiquities presents much greater difficulties than that of the antiquities of other parts of the world. There is no history of the nations who erected them; there are no facts on record with which we can connect them. We do not know by whom and under what circumstances these remarkable monuments were erected; nor do we know what purpose they were intended for. In the great majority of cases, the antiquities of Europe we find in most cases that these circumstances can be ascertained. Either the erection of these buildings is recorded in history, or some inscription or other indicates the time in which they were erected and by whom. There are a few antiquities, such as the Celtic remains, as to which some discrepancy of opinion exists, but even here we can approach to probable conclusions. The monuments of Egypt are covered with the names of kings who erected them, and the Greek historians have not recorded such traditions as were current in Egypt when they visited that country. We cannot say so much of the rock-cut temples and other great monuments of Hindustan. Few inscriptions are found on them, and the nations who erected them are remarkable for their neglect in recording historical facts. But the sculptures which adorn these monuments are so closely connected with the present state of society in that country and with the religion of the people, that it may be asserted that they mutually explain one another, and that a person who is thoroughly acquainted with the people and their religious institutions is enabled to understand the sculptures on the monuments. In this way nearly all the ancient monuments of the Old World may be explained by the aid of historical records or inscriptions, or by their evident connection with the present state of the inhabitants. But the monuments of America are not in the Old World. They are not mentioned in historical records, nor do they contain inscriptions. It is true that many of them contain hieroglyphic characters, which were probably sufficient to explain them to the ancients who erected them and knew their significance. But to us they are dead letters. We do not know the state of society of the people who erected them, and we are unacquainted with the meaning of the hieroglyphic characters. Further, we cannot derive from the present condition of the nations of America anything which can explain their antiquities. Their condition has been abruptly and greatly changed, much more so than that of the nations of Europe when their countries were inhabited by the ancient Greeks and Romans. The people of the fourth and fifth centuries issued from the central parts of Asia and the north of Europe. The Spaniards, who conquered the most civilized portions of America, had urgent political motives which distorted the records of their conquest. We are thus enabled to judge of the degree of authority with which they conquered and to reduce the whole population to a state of degradation; and what they began from political motives, they finished from religious zeal. It is quite impossible to connect the present condition of the native population of America with any of the monuments now remaining, whether they were built by the Maya, or the Aztec, or Chichen, or to draw from it any facts which can elucidate the monuments, though it is probable that these monuments were erected by the ancestors of the present native inhabitants.

AMIGONI, JACOPO, one of those painters who, by some chance not quite apparent, obtained a popularity in his life time immensely beyond his deserts according to more modern critics. He was born at Venice in 1675. After he had acquired some reputation in Venice, he added considerably to it in the service of the elector of Bavaria, by some works he executed for the Schleissheim; and when he returned to Munich, another elector caused some fresco ceilings to be executed at Schleissheim. He had with equal success in London, where he came in 1729, and painted a few staircases in fresco, and many portraits in oil. He painted also Shakspere and the Muses over the orchestra of the new theatre at Covent Garden. He died at Venice in 1739, having saved 5000l. during his ten years' stay in London. In 1747 he went to Madrid with the appointment of painter to the king, Ferdinand VI. He died at Madrid in 1752, where two of his daughters were still living in 1778, both married to some of them, Signor Castellani, practised as a portrait-painter in crayons.

Amigoni's frescoes are purely ornamental, mere variegated decorations; the following is Wallpole's critique upon his picture of the Thames, several years afterwards.

'His manner was a still fainter imitation of that nervous master Sebastien Ricci, and as void of the glow of life as the Nespoli Solimena; so little attention do the modern Venetian painters pay to Titian, Tintoret, and Paul Veronese, even in Venice. As Leonis' women are mere chalk, as if he
and only painted from ladies who paint themselves. Nor was this his worst defect; his figures are so entirely without expression, that his historical compositions seem to represent a set of actors in a tragedy, ranged in attitudes against the curtain, as in the productions of Mr. plot himself. Yet, notwithstanding this, his pictures are so free and easy in design as to please his contemporaries. Yet novelty was propitious to Amiconi, and for a few years he had great business.

He painted some small conversation pieces in the style of Sandrart, and later, in the very highest manner, as to his larger works. Of the latter one of the best is a Visitatio, at the Padri di San Filippo at Venice. He engraved a few prints for his masterpiece, and instructed Joseph Wagner in engraving; so many works of Amiconi, the principal of which is Melchior, Heine engraving 127, include of the portraits of several crowned heads, among them Peter the Great, and one pope, Benedict XIV.

AMMANI, JOST, a celebrated Swiss engraver and designer of the sixteenth century, born at Zurich in 1528. Though a Swiss by birth, he was a German by adoption, for he established himself in Nürnberg in 1560, and gave up his right of burghership in Zurich in 1577. He is the case with most of the old German masters, little or nothing is known about him, save what is contained in his colosal study, and the few engravings that yet are not a single painting of his known. Sandrart and Doppelmayr speak of him as a painter on glass only. Amman's designs are extremely numerous; a painter of Frankfurt, of the name of Keller, who lived with Amman four years, tells his principal to do with his designs; but while the size of his work would fill a large wagggon. Though he did not live long, he surpassed every artist that preceded him in the number of his designs. There are about a thousand wood-cuts attributed to him, but whether he cut all or even any of them himself is not known. Bartic also doubts whether all the etchings attributed to Amman are etched by him; he supposes some to have been etched by Stephen Hermann. His designs generally appeared as the illustrations of books; few books were printed with them, except the two large folios, one published in 1541, and the other in 1547; the former was published by the most of Amman's works; many of them were published after his death. He died at Nürnberg in 1591.

His works comprise nearly every subject—History, sacred and profane, general costume, military costume, field-sports, natural history, heraldry, and other subjects. His drawing is generally good, and in the costume very accurate and evidently drawn from nature; his animals also are executed with much spirit. Sandrart describes him as a very assiduous man, of a quiet and decided character; but if his strokes are more regular than usual with the engravers on wood of his time, it is to be feared as much as he gained by the pains he took with this labour, he lost in the execution of the same.

One of his most remarkable works is Fluvia, published first at Frankfurt in 1564; again in 1574, and again in 1588. This book is very scarce; it is a description of all the principal towns and occupation of Amman's time, containing 116 illustrations on wood of various mechanical and tradesmen, &c. in appropriate costume; he has represented himself as the engraver. Hans Sachs used Amman's plates for his work entitled 'Einige liebliche Beschreibung aller Stände auf Erden' (Particular Description of the Society of Men upon the Earth), printed at Frankfurt in 1568 and 1574.

Another remarkable work is 'Icones Livianae,' &c., published also at Frankfurt, in 1572 and 1573, containing 103 illustrations of the Roman History. They were published also with some additions and a German translation of Livy in 1573, in the same place; and again at Strasburg in 1613. The first cut is a portrait of Feyerabend, the publisher.

Feyerabend published also, in 1564, 103 illustrations of the decoral and monastic costumes of the Church of Rome, with Latin descriptions; but three German editions have since been published. And also a book of female costumes with 120 cuts, entitled Costume, as Theatre of the World, &c. published at Frankfurt, 1586. Also the same place, the book of Plays the elder, 1584; a folio set of 12 illustrous women, beginning with Eve, on copper; and in 1587 a Dance of Death, 'Der Toten Tantz,' in 49 cuts; besides many other works.

Amman was also an author: he wrote a book on poetry, panting, and sculpture, which was published at Frankfurt, first in 1578, and later as a Manual of Painting, 'Arta Pincere.' Enshehrird.'

(Sandrart, Deutsche Academie, &c.; Doppelmayr, Historische Nachricht, &c.; Stutt, Dictionary of Engravers; Heinecken, Dictionary of Woodcutters, Fussli, & Nagler; & Le Peintre-Graveur of Bartusch.)

AMMANATI, BARTOLOMEO, this distinguished sculptor and architect was born at Florence in 1511, and died at Rome on the 22nd of February 1574. Thus it was, that the former part of the wall of the church of the Jesuits in Rome, was completed by his own hands, and the latter part by his own pupils. He was educated in such a nursery, with Basnio Bandinelli and Sansovino for his tutors, he could not easily fail to produce works worthy of his opportunities and his education. His father, Antonio da Sebignano, died when Bartolomeo was young, but he left Bartolomeo under the care of a neighbor, to be in a condition to choose his own profession and to follow it.

When Ammanati returned from Venice to Florence, Michelangelo was at the height of his reputation as a sculptor, and Ammanati became one of his most devoted admirers and imitators, and, like many other painters and sculptors, catching chiefly the defects of Michel-Angelo's style, fell into the error of treating the limbs as the most essential part of man. In this spirit Ammanati executed several works in various cities in Italy. He made three great figures at Naples for the monument of the poet Sannazzaro; a colossal Neptune for the Plaza di San Marco at Venice; a colossal Hercules at Padua; the Neptune of the Piazza del Gran Duca at Florence; and the figure of Ammanati's Ancestors at the Piazza di San Miniato, at Prato, near Florence. The Neptune of the Piazza Gran Duca was ostensibly designed in competition with Benvenuto Cellini, the Fleming John of Bologna, and Vineceo Danti; but according to Cigognara, the competition had been rescinded, and the commission awarded to Ammanati's design, the duke, says Cigognara, did not even see the designs of two of the competitors.

Ammanati was also much employed in Rome by several popes, curts by Paul III., Julius III., and afterwards by Gregory XIII.

During the interval between the two periods that he was employed by these pontiffs, he attained great fame at Florence as an engineer and an architect. He constructed the celebrated Ponte della Trinita, in which a turned arch was light and elegant elliptical arches, calculated to allow the sudden floods of that river to pass without the slightest risk, it still exists, and has withstood lately (1844) the most important flood that has visited the Arno for centuries, in which even the newly constructed iron suspension-bridge was swept away. The old Ponte della Trinita, which was replaced by the bridge of Ammanati, was destroyed by the floods of 1567. Ammanati made also some additions to the Palazzo Farnese, the new court of the Farnese. He was commissioned to design and to superintend the construction of the cornice of the church of the Jesuits, and has been finished only within the last ten years. At Rome he built the Palazzo Rucellai, afterwards Ruspoli; the court and facade of the Collegio Romano, built for the Jesuits; the temple of Venus and Rome in the Propolet; and the church of the Suor in Via, dedicated to the Corneli family. His principal works of sculpture in Rome are the figures of Justice and Religion and the other sculptures of the tomb of the Cardinal del Monte in the church of San Pietro in Montorio. Many of the works of Ammanati are naked, which, as he grew old, he seems to have deeply regretted; and he wrote a letter as an apology to the Academy of Florence, which was published in 1562, and in which he exhorts the rising artists to drave their figures, the representation of the naked being, as he then thought, offensive and injurious. Baldinucci has reprinted the letter. His wife, to whom he was married in 1560, was the celebrated Laura Battiferri of Urbino. He distinguished himself as a member of the Society of the Internati of Siena. Her poems were published twice, at Florence in 1560, and at Naples in 1569. She died at Florence in 1589, aged sixty-five. Ammanati survived her three years, and died, according to Baldinucci's account, on the 16th of December 1592, at the age of sixty-six. His body was laid near his wife's, in the chapel of San Bartolomeo, which he had prepared for the purpose, in the church of the Jesuits, San Giovanniino, at Florence. He bequeathed the greater part of his property to the Jesuits and the Society of the Internati of Siena.

There is in the library of the Florentine Gallery a manuscript by Ammanati, entitled 'La Citta,' in which he has treated of all the buildings necessary for a city.

(Baldinucci, Notizie dei Professori del Disegno, &c.; Cigognara, Storia dell'Arte, &c.)

AMMODYTE, a genus of fishes belonging to the division of Apodot Malacopterygii and family Angiitoidei. The
body is very long and the head lanceolate. On the back is a dorsal fin extending nearly its whole length. The anal fin is also long; and the caudal, which is forked, is separated from both the dorsal and anal. Two species occur on the coasts of the British Islands, the Ammonia lancea and the Ammonia dubia. The former is the larger, and is distinguished by the greater size of the head, and by the dorsal fin, which commences in a line with the extremities of the pectorals, whilst in the A. lancea it commences in a line with the middle of the first ray of the Sand-Eel, and this species is popularly known, attains a length of between 12 and 15 inches. When alive the back is of a dark bluish-green, and the sides and bellies bright silver-white. It frequently sand-aborbs a great number of fish, and is thus a most dangerous in approaching the shoals. At the ebbing of the tide it buries itself with great dexterity and rapidity in the wet sands to the depth of from 4 to 6 inches, whence it is extracted by means of various instruments, such as peculiarly formed grippers and sickles with blunt edges, made for the purpose. It is much esteemed by fishermen as a bait, and is also sought after on many parts of the coast as an article of food, being very delicate eating when fresh, and excellent when dried in the sun and grilled.

The sand-lance, Ammodytes lancea, is a smaller species, and usually of a more brownish hue, with a tinge of red about the head. It is more abundant than the Sand-Eel, and has always been distinguished from it by the fishermen, though for a long time associated with it in scientific works. The distinctions between the two species were first pointed out by M. Leasug of Caen. Both appear to be generally distributed through Northern and Western Europe. In Scotland the Sand-Eel is the same name as the Horner, and in the Isle of Man the two species are distinguished from each other as the Grey Gibbon and Red Gibbon.

(Yarrell, British Fishes, vol. ii.; Parnell, Fishes of the Frith of Forth.)

AMMOCHEMI—Medical Properties of. This alkali is distinguished from the others by the application of Volatile, because at the ordinary temperature and pressure of the atmosphere it never exists in a fixed state, but either in a gaseous form, in which it is immediately combined with any carbonic acid which it encounters in the air, or is absorbed by water or spirit, from both of which it is easily liberated, particularly if heat be applied. Having been formerly obtained by distillation of shavings of hawthorn or other animal matters, it is familiarly known under the name of Spirit of H纳税ton. The combinations with carbonic acid have the same properties as the pure alkali, in respect to volatility, and only a diminished degree of causticity.

The gas in an ascertained state is highly pungent, with a suffocating odour, is irreparable, and irritates and inflames the animal tissues. (Christison.) Diluted by passing through the air, from which it absorbs moisture and carbonic acid, which serves further to lessen its acrimony, it is occasioned to be of service to the alchemist and confectioner, and to keep up vigilance in cases of somnolence from narcotic poisons.

This last mode of using it is scarcely to be recommended, as dangerous inflammation of the eyes may subsequently follow. Indeed all employment of even the less caustic forms of administration, when much insalubrity exists, such as in fumigations, epileptic fits, or from narcotic poisons, likewise in experiments on persons in the state termed manieeric coma, requires great care. Fatal inflammation of the eye and stomach has been occasioned by merely holding carbonate of ammonia (smelling salts) or a handkerchief dipped in strong aqua ammoniae under the nostrils. (Nysten.) When it is to be introduced into the stomach, this should be done by means of the stomach-pump, to avoid any of it passing into the windpipe. Besides its local action, exciting inflammation and its effects, ammonia is itself poisonous, its secondary effect on the nervous system, particularly the spinal column, being sufficient to cause tetanic convulsions. Though Eau de Collod is used to adv. cold weather is unsafe for children.

(See Lancet for April, 1844.)

Amoniacal gas absorbed by water constitutes the aqua or liquor ammoniae. This is formed of two different degrees of strength: the one of a density of 962 at 26° F. called fortior, much used in chemical experiments, by no means the most suitable for some chemical processes; the other of the density of 960, which also generally requires to be diluted further with water when intended for internal use, or with oils when for external use, as it is very frequently to form refrigerating liniments.

The solution of the carbonate likewise frequently employed in combination with oils. These, if long, if frequently repeated, cause inflammation which terminates in suppuration and ulceration.

Ammonia, when suitably diluted to be taken into the stomach, is used in doses between the 20th and 30th drops of the nervous power. Hence it acts as a prompt and valuable counter-poison to Prussic Acid, the bites of serpents, and the poison of many diseases, such as Cholera Asiatica, and typhoid fevers, at the commencement of which great depression of the nervous system is often observed; in such cases of depressio, such as the languor of hysterical females, or in atomic goit, ammonia or its carbonates are daily resorted to. It is likewise employed to counteract acidity in the stomach.

The use of ammonia should be kept warm, especially in the fasting state. The use of ammonia produces the same ill effects as the other alkalies when taken in excess. (Aylie, P. S.)

The salts of ammonia require a brief notice. The properties of the different combinations of ammonia with carbonic acid are too similar to those of the pure alkali to be noted separately, except to state that carbonate of ammonia furnishes a good emetic in the earliest stage of fever with great depression, and is in smaller doses given freely throughout all adynamia fevers, sometimes in the effervescing form, especially when action of the skin is desired. Citric acid is employed to cause it to effervescence.

Hydrochlorate of ammonia is little employed in this country internally, but it may be beneficially used in combination with astringents. (I. H. P., vol. vi., p. 699.)

It is obtainable chiefly employed to form disinfecting and evaporating lotions in conjunction with vinegar and spirit. For these it is most valuable.

The latter of these sometimes are given in doses of two grains, and in this state, the causticity of the pure alkali or the carbonates, neither is it volatile. It is so delusive that it cannot be kept in the solid form, and is always administered in weak acetic acid. This forms a most grateful refrigerant at the commencement of slight inflammatory complaints, and if the patient be kept warm, generally relieves the perspiration. For this purpose it requires to be freely given. It is also a diuretic, but not much employed. Properly diluted with rose-water it forms a cooling eyewash, most grateful after instances of inflammation, to relieve the turgescence which remains, or for a removal of turgescence which may have been preceded by inflammation. Scarpia thought it useful against commencing amanuaris.

AMMONIA—Medical Properties of. This gum-resin is fully described in P. C., vol. i., p. 498, where it is ascribed, on the authority of the former edition of the London Pharmacopoeia, which was missed by Willdenow, to the Heracleum gumifcrum, Willd., an error corrected in the subsequent one, where it is correctly referred to the Doresa ammoniacum (Don, in linn.) which was discovered by Lieut.-Col. Wright, growing near Yezd Khést, a town of Irāk Ajem, the antient Perses, about 42 miles south of Isphahan. Its Persian names are Coosh and Math, and it is said to be a native of the countries now called Persia, and used in the herbs of Persia. It is a resin, very abundant near Herst, likewise abundantly in Sygah, near Buncanec, on the north-west slope of the Hindu-Cooch range of mountains. (Christison.)

Ammoniacum was not known to the antients: but it is supposed that what they used came from Afgis as well as Asia, and was procured from a species of Ferula, either the F. orientalis (Linn.) or the F. t Ignaria (Linn.).

The Persian plant yields the juice chiefly from the stalk, especially at the points of division of the umbel, owing to the punctures of numerous coleopterous insects. 'The gum is so abundant, that upon the slightest puncture being made, it instantly oozes forth, even at the ends of the leaves.' (Capt. Hart, Trans. of Medical Society of Couchiwt, vol. i., p. 509.)

The juice quickly dries, and is either picked off or allowed to accumulate till it falls on the ground. This collection takes place about the middle of June. A tenth part is remitted as tribute to the government; the rest is sent to Bushire, on the Persian Gulf, and thence through the Cape of Good Hope to Bombay. The juice of the Sygah plant is obtained by making successive slices of the root, as in the case of asafoetida. The samples vary much in quality. The directions given to purify the inferior sorts, by softening them in boiling water, and then blotting dry, and thus purgative in effect, and causing moving mechanical impurities, impair the power of the gum-resin, by driving off the volatile oil, which even in good specimens is not very abundant, 32 ounces yielding by distillation only one drachm.

The official form for administering ammoniacum is the
The group of Arietes, including Amm. Bucklandi, A. Co-nybeerii, &c., belongs almost wholly to the lias formation.

Paeliferi.—The back is narrow, and acuminated to a sharp keel (no furrow on its sides); the ribs are elegantly and sigmoidally bent. The sutures differ from those of the Arietes, the dorsal sinus D being much less deep, with diverging and not parallel sides; the sinus L is very much deeper, and there are three or four smaller ones, a, b, e, near the inner edge of the whorls. The latter whorls usually embrace the preceding ones.

The Ammonites are numerous in the upper lias and lower oolitic formations. A. Sturkei of Cowbery is an example. (Ammonites Walcottii does not belong to this division.)

Amaltheii.—The back is generally acute and keeled, the keel generally crested; the ribs generally a little sigmoidal; the latter whorls embracing the preceding ones. The sutures are in general form much like those of the last division, but more richly lacerated and foliolaceous.

This group belongs to the upper lias and oolitic formations. Ammonites amathaei of Schlotheim (A. Sturkei, Sowerby) is an example from the lias.

Capricorni.—The back broad, without a keel. The ribs simple, straight, strong, and crossing the back. Inner whorls exposed. The sutures often approach to those of the Arietes in character. Perieira has their usual range on the same line, and the undulations are all lower and less foliolaceous than in the Paeliferi and Amalthei. Ammonites planicostatus (Sowerby) is an example. The species are common in the lias.

Planulatti.—The back and sides rounded; no keel; the inner volutions exposed. The ribs are often divided over the dorsal region. The sutures are remarkably lacerated and complicated; the sinus (L) extremely deep, and generally trifurcating.

The species occur commonly in the lias and oolitic formations. Ammonites communis, Sowerby, is an example from the lias; A. plicatissim, Sow., from the coralline oolite.

Dorcati.—The back is broad and not keeled; the whorls often quadrate; the ribs are simple on the sides, but divided over the back, and generally bear a tubercle at the point of division. Ammonites Davos, Sowerby, is an example from the lias.
in commerce, viz. short, short-long, and long-long, placed in the order of their merit. The first and best are about three to six lines long; the second about six; the last from seven lines to an inch. From this analysis he found the small carminatives, and obtained—essential oil, 4°/6; fixed oil, 10°/4; a salt (probably malate) of potash, combined with colouring-matter, 2°/6; fecula, 3°/0; nitrogenous muclage, with phosphate of lime, 1°/9; yellow colouring-matter, 0°/4; and woody fibre, 7°-8.

The fixed oil somewhat resembles castor oil. The excellence of the specimen depends on the volatile oil; this is small in inferior kinds; the best yield about six drachms and a half of the fruit. The experiments were run only four scruples for one pound of fruit. Like oil of terepine, lemon, &c., it consists only of carbon and hydrogen.

Ceylon cardamoms, or larger, sometimes termed long, are produced in that island; but some of the less valuable of the Mistletoe, and seconded Ceylon cardamoms, who have in their possession are liable to heavy penalties.

[ADULTERATION, P. C.S.]—The duty on grains of paradise was reduced from 2s. per lb. to 15s. per cwt. by 5 & 6 Vict. c. 47. Cardamoms are in great favour in the East as a spice, and also introduced into Europe after the fall of the Mamluk in 1258. In the last part of the 16th century, they were as highly esteemed as carminative and stomachic agents. Dr. Christison observes that they form part of eighteen official preparations, besides their own tincture.

AMONTONS, GUILLAUME, a diligent mechanician and experimentalist in natural philosophy, was born at Paris in August, 1663. He was, during all his life, afflicted with dizziness in consequence of a fever in his childhood; and, after a sickness which lasted but a few days, he died in October, 1705, being in the forty-third year of his age.

The taste of Amontons led him, at first, to the study of architecture and the processes of land surveying; and he applied himself particularly to the principles of both those branches of art. It is said that he was induced to apply himself to the study of mathematics by the desire of constructing a machine which should exhibit a perpetual motion: an opinion of the possibility of such a machine certainly lingered among the half-leaved of that age; and, if Amontons really attempted to form one, his failure had the good effect of disposing him to cultivate the legitimate branches of science.

In the countries are instruments employed for measuring the density, temperature, and humidity of the atmosphere were in an imperfect state; and several years of the life of Amontons were spent in improving them or in devising others. He invented a barometer, consisting of a slender conical tube of glass, which was filled with mercury and variegated with the variations in the upward pressure of the atmosphere on the base of the column; the open end of the tube, which was the greatest, being below, and the mercury being retained in the tube by a leaf of lead. He also invented one, consisting of a tube bent so as to form three parallel columns, of which the first and the third contained mercury, and the intermediate one air. Amontons contrived what he called a universal thermometer: it was a tube of glass, 30 inches long, containing mercury, and to which was adapted a scale of inches; and, by comparing its indications with those of a column of mercury in an ordinary barometer, he was able to determine the expansion due to temperature alone: he also invented a magnetometer, consisting of a tube of glass, filled with a fluid contained in a glass tube which terminated below in a leather bag. The contraction or expansion of this bag, in consequence of variations in the humidity of the air, produced corresponding variations in the length of the column of fluid.

But the most remarkable instruments employed by Amontons in the life of Amontons is his invention of what must be considered as a species of telegraph. His proposal was to have signal-posts established at intervals between the two extreme stations, which were to be Paris and Rome; a map at each post, being provided with a telescope, was to observe the signal (a letter of the alphabet) made at one station, and to repeat it to the next; the process being carried on thus along the whole line. Two experiments are said to have been made by him in 1715 in practice. The result of this family of experiments was not, however, with what success. Dr. Hooke had however anticipated the discovery about 18 years.

The only work which Amontons published is one entitled "Remarques et Expériences sur la Construction d'une nouvelle Clepsydra, sur les Baromètres, Thermomètres et Hygromètres," Paris, 1695. He was subsequently a member of the Académie des Sciences; and among the "Mémoires" of that body are those of Amontons on the expansion of fluids by heat, on the muscular strength of men and animals, and on the friction of materials.

AMPERE, ANDRE MARIE, was one of the many scientific men who, since the commencement of the present century, have contributed to the development of the highest branches of mathematical analysis to physical propositions, particularly to such as relate to electricity, magnetism, and light.

Of his private life little is known; and, like that of many men who have devoted their days in scientific pursuits, consists merely in statements of his birth and death, with a list of the works which he composed. He was born at Lyon, in 1775, and it appears that he resided in or near that city till about the year 1800, when he removed to Paris, where he died in 1836. Before this removal he was professor of physics in the central school of the department of Ain; and, subsequently, he held the appointment of professor of analysis in the Polytechnic School of Paris.

His anterior contributions to science are enumerated in the "Annales de Mathematique" (Lyon, 1802), in which it is satisfactorily proved that, if a person play habitually in society, he must infallibly, even though he play on equal terms, be ruined.

In 1803 Amontons published a work entitled "Recherches sur l'Application des Forces Géométriques du Calcul des Variations aux Problèmes de Méchanique," and in the "Annales de Chimie" (1814) there is published his letter to Berthollet on the subject of Definite Proportions, or the Analogy of the Laws of Glacial and of Chemical Action.

Some connection between the electric, galvanic, and magnetic powers in nature had been long suspected on account of the observed effects of lightning on the directive property of a magnetized needle; and in 1819 M. Oersted observed that the wire connecting the opposite poles of a galvanic or voltaic battery caused a magnetized needle suspended near it to deviate from that position which it assumes when beyond the influence of any disturbing power. This remarkable phenomenon being clearly exhibited to the philosophers in Paris, who conjectured an important discovery, at once corrected that same one; and a little more than five minutes, the current repeated the experiment in various ways; and almost immediately, by the discoveries to which their researches led, raised up a new branch of science. Among the earliest of these philosophers was Ampère, who, in September, 1820, published a paper before the Academy, in which it was stated that the voltaic pile, or galvanoic trough itself, produced a like effect on a needle suspended near it; when its opposite poles are connected by a wire; and soon afterwards M. Biot communicated an important discovery by which it was proved that some, at least, of the phenomena of magnetism could be represented by electricity alone. He showed that if two wires connect the opposite poles of a battery, they attract one another when so disposed that the currents pass along them in the same direction, and repel one another when the currents flow in contrary directions; and he contrived a delicate apparatus by which the phenomena were exhibited.

Ampère, having discovered that if a wire be suspended over one pole of a magnet, and the galvanic fluid be made to pass along the wire, or if the wire be fixed and the magnet suspended over it; the wire in one case, and the magnet in the other, would revolve about the fixed object; Ampère, to whom the discovery was communed immediately repeated the experiment, and subsequently contrived an apparatus in which the suspended magnet was, by the influence of the wire, made to revolve on its own axis. He also invented the well known voltaic galvanoelectric apparatus, consisting of a cylinder containing three cylinders, being supported by conical points over one end of a magnet placed in a vertical position, revolve about the magnet; or, in the right hand, and to the left; or, in the contrary direction if the south end be uppermost. M. Arago afterwards, in conjunction with or at the suggestion of Ampère, succeeded in communicating magnetism to a needle
AMV

by placing it within a helix of copper wire, the extremities of which were connected with the poles of a battery.

From the mutual attractions and repulsions existing, apparently in electrical, or, as they may be called, electro-magnetic currents, Ampère inferred that such currents revolve continually about a magnet; at first he supposed that the centres of their revolutions were in the axis of the magnet, but he was quickly dissuaded from this supposition by experiments. It was found that the electric current was produced in the wire as long as each atom in planes a little inclined to the general axis of the magnet; setting out with this principle, he satisfactorily deduced, by analytical processes, the phenomena of electro-magnetism. The phenomena of electricity, however, have been developed and elucidated by hundreds of thousands of experiments, and it is evident that much has yet to be discovered. Mr. C. F. Wheatstone has recently shown, in fact, that the magnetic action of the earth is the result of currents circulating within it, or at its surface, from east to west in planes parallel to the magnetic equator: he also imagined that these currents act on balanced suspenders, which, like magnetized needles, contain electric currents, causing them to place themselves in such positions that the currents on their under sides may flow in the same direction as those of the earth. He contrived several ingenious machines in which terrestrial magnetism was an agent: among others, he disposed a wire bent in the form of a rectangle or a spiral, so that the plane might turn on a vertical axis, and, placing it in the position of the magnetic meridian, he allowed the electric current to enter at either extremity, when it revolted from the current's direction; on the other side, when it became at right angles to that meridian. He also exhibited to the Royal Academy of Sciences a copper wire bent in the form of a helix which possessed the properties of a magnet: he subsequently placed the helix, each way, to the middle, from whence they passed out in opposite directions and served as pivots on which the spiral might turn. When the pivots were connected with the poles of a battery, each end of the helix, on a pole of a common magnet, was attracted to the poles of the battery.

Ampère published at Paris, in 1822, a work entitled "Recueil d'Observations Electro-Dynamiques"; in 1824, one which was designated "Précis de la Théorie des Phénomènes Electro-Dynamiques" (both of these are 8vo.); and in 1826, in 4to, "Théorie des Phénomènes Electro-Dynamiques." Two years afterwards he published a "Mémoire sur la Determination de la Surface courbe des Ondes lumineuses, &c., &c." and six years subsequently an "Essai sur la Philosophie des Sciences, &c." Besides these works there were published separately several memoirs relating to his experiments in electro-dynamics; also, in the "Mémoires de l'Institut," in the "Journal de l'École Polytechnique," and in other works, many papers relating to Mechanics, Optics, and Natural History.

(Addressee H. R. H. the Duke of Sussex to the Royal Society of London, 1836; Barlow's Essay on Magnetic Attractions, Turner's Elements of Chemistry.)

AMPHETHIUM, a genus of fish, from the Isle of Shetepy, (King's, Icon. Fossil.)

AMPHIDURETUS, a genus of Echinida, found in the coast of Suffolk.

AMPHIORIUS (Pander), a genus of fossil Crustacea (TriLOBITAE), four species of which have been described, from Tyrone and Waterford, by Captain Portlock.

AMPHIOXUS. [Branchiostoma, P. C. S.]

AMPHITRITE (Blainville). This fossil mammal, from Stonesfield, is now termed Sphenothalamus by Owen.

AMPLEXUS (Sowerby), a fossil genus of MADREPOLOides, P. C., remarkable for the simplicity of its structure and the variability of its general figure. "Occurs in the mountain limestone." (Barlow's Elements of Chemistry.)

AMPYX (Dalman), a genus of fossil Crustacea (Trilobite), four species of which have been described by Captain Portlock, from Tyrone.

AMYGDALUS.—Medical Properties of. Amygdalus communis, a tree native of Asia and Africa, cultivated in the southern parts of Europe, of which there are two varieties, sweet and bitter. Of the sweet almonds the parts which are official are the seeds or kernels. When covered with the skin, or protected by the outer covering of moderate weight and traversing the skin, and forming a raphe. Dissected of the skin, the egg-shaped seed, formed of two cotyledons, is seen of a white colour. They have a sweet and mucilaginous, rancid, only taste, and scarcely any odour when fresh, but when pressed to the press, and when ripe, they are strongly aromatic, and acquire a rancid, oily odour.

Analysed by Boullay, they yielded emulsion, and a fat oil of a very bland kind. Ten pounds of seeds yield four pounds of oil. Upon being subjected to pressure, or treated by means of either, the oil is separated, and there remains the cake, or farina amygdalae. The commercial varieties are numerous, but the most esteemed are the Jordan almonds.

Triturated with water, sweet almonds form a grateful, sweetish emulsion, which possesses considerable nutritious as well as demulcent properties. This emulsion should never be prepared long before it is required for use; as, besides the uncertainty of species, it is the risk, when bitter almonds are employed, of some of the poisonous products being developed. Almond paste forms a good emollient application to chapped hands in winter.

Almonds, as both a food and a medicine, are nutritive, but rather indigestible. In some persons they occasion, more particularly bitter almonds, an eruption similar to nettle-rash, and other troublesome symptoms.

Oil of Almonds. The almonds having been freed from the skins must be bruised, and pressed in cold, or, if warmed, they must be pressed in iron presses. The oil when first obtained is turbid, but becomes pure by time or by filtration. It is yellowish or nearly white, if the almonds have been completely freed from the skins before being pressed, translucent, and when cold-drawn is without odour. The taste is purely oily. Specific gravity, 0.911 to 0.920. Consists of, chief, stearin 25. It is tolerably fluid at the ordinary temperature of the air, but a reduction of temperature becomes turbid and white, and by a still further reduction of temperature and as an oil it takes up 1-25th part. Sulphuric acid and the volatile oils combine with it in every proportion. Caustic potash forms with it a very solid soap. When it has been carefully expressed, it dries when in contact with the air so as to be almost impervious.

It may be obtained freely from either variety; but is yielded in greatest abundance by the bitter almond. Ten lbs. of sweet, when cold-drawn, yield from 4 to 4½ lbs.; 16 lbs. of bitter almonds yield 7 lbs.

Almonds which have become rancid yet yield by expression good oil; if a little calcined magnessia be added to the bruised almonds before being subjected to pressure.

Almond oil is often adulterated with poppy oil. It is employed more as an external application, especially to the ears, than internally.

Amygdal, Amaran, bitter almonds, are smaller and flatter than the sweet. Those most esteemed come from Prussia, those least esteemed from Barbary. They have a bitter taste, and scarcely any odour, but if rubbed between the fingers with a little water, they emit a peculiarly agreeable odour. Triturated with water they form an emulsion, which by distillation yields a volatile oil, containing hydrocyanic acid. This oil is procured in very variable quantity; one pound of almonds yielding in some instances one drachm, in others only fifty grains, in others ten grains.

A fat or fixed oil is also contained, which may be procured by expression. Hence in the Pharmacopoeia, Oleum Amygdalinum is described, to be expressed from the kernels of either variety. For the sake of economy this fixed oil is first procured, and the cake which remains is employed either to yield the volatile oil containing hydrocyanic acid, or to furnish Amygdalin.

Amygdalin is a peculiar product, containing nitrogen. It does not possess the poisonous properties of hydrocyanic acid; yet it is one basis of that powerful agent, and some account of it is necessary to understand the manner in which other almonds occasionally possess this property. It is prepared as follows—the cake remaining after the fixed oil has been expressed is to be treated with boiling highly rectified spirit, containing not less than 80 per cent, of alcohol, so long as anything is drawn up by the spirit. The spirit is continually renewed, when the cake is freed from the spirit, and the residue dissolved in water, then filtered and crystallized. The crystals are to be purified by repeated crystallization. They are either in the form of small colourless shining prisms, or mucicaceous plates, devoid of odour, having at first a sweetish taste, but afterwards extremely bitter. They are not volatile, but are easily soluble in water, without undergoing the slightest alteration; less soluble in alcohol, and not soluble in ether. Geiger thinks this principle worthy the name of Amygdalin.

It is this substance which, when acted on by the emulsion, and water, forms both the hydrocyanic acid and the volatile oil of bitter almonds. The former will be amply treated of in P. C. S. [Hydrocyanic Acid]. The latter requires to be connected with the subject of the inferior in power to prussic acid. Its specific gravity is greater than that of water. It is soluble in alcohol and ether. It is a compound of a very complex kind, containing hydrosol.
cyanic acid, hydroure of benzal, benzoic acid, benzoin, benzamide, etc. (Pereira.)

It is sold in different degrees of dilution to cooks, confectioners, and others, to flavour cakes and liqueurs, under the name of essence of nataha, peach-essence, &c. (S. L. O., 1854, published similar but Pereira.)

From its inindescribable use, as well as variable strength, many fatal cases result from it. It is also used as a criminal means of destroying life.

ANABAS (from αναβαίνω), to ascend), the name given by Cuvier to a genus of Acanthopterygious Oseous fishes, remarkable for the power possessed by the species of living for some time out of water and making their way on land. This power depends on a structure characteristic of the family of which it is the type, part of the pharyngeal being laryn-thiform, that is to say, divided into a number of irregular lamellae, more or less numerous, forming cavities and little cells capable of retaining a certain quantity of water. This apparatus is so protected, that when the animals are out of their native element the evaporation of the contained water takes place very slowly, and the gills are kept moist, by means of which remarkable provision the fishes of this family are enabled to leave the rivers and marshes where they usually reside, and to travel over land for considerable distances, creeping among the herbage or along the ground. Although this fact has been hitherto known to modern naturalists, the antiquits appear to have been well acquainted with it, and Theophrastus has recorded the existence in India of certain little fishes which leave the rivers for a time and again return to them: he doubtless alludes to the Anabas and its allies.

The genus Anabas, of which there is but one species, the Anabas scandens (Verca scandens of Daldorf, Anthias testudinse of Bloch), is distinguished by a well-marked character, the borders of its opercle, subopercle, and interopercle being dentiliculated, whilst the preopercle is not so, nor even distinctly margined. The head is round and broad; the muzzle is very short and obtuse, the eye placed very near its extremity. The mouth is small, and large scales cover the head. The body is oblong, compressed centrally and behind. The lateral line is interrupted at its posterior third, recommending a little lower. The tail is somewhat rounded. The whole body is covered with large scales. There is a single dorsal and an anal fin, nearly equal in height, and in both the spines rays prevail. The formula of the fin-rays in the Anabas scandens is as follows:—

D. 17 or 16-9: A. 10 or 11-10: C. 16: P. 15: V. 1-5.

In colour it appears to vary, being brown or bluish-black or dark green, paler beneath and having violet fins. In form the individuals are constant, and reach the length of six inches.

In 1879 a Danish gentleman, M. Daldorf, communicated an account of its habits to the Linnæan Society of London, in which he stated that he had observed it in the act of ascending palm-trees near marshes, and had taken it at a height of no less than five feet above the surface of the water, effecting its movements of ascent by means of its fins and tail and the use, when of necessity, of its pectoral fins. The latter is in a similar manner that by which it progressed along the ground. Another Danish observer, M. John, published a similar statement, adding that it is called in Tranquebar panneri-et, a name which signifies: their means of ascending, who have equally observed it in its native countries, such as Reinwardt, Leschenault, and Hamilton Buchanan, whilst they record its habit of creeping on the ground and living a long time out of water, decency or omit all mention of its power to ascend trees.

The fish—but not all the species of the family—belong to the genera Helotoma, Polyacanthus, Colisa, Macropodus, Ophromenes, Trichopus, and Synbranchus, of which the habits are as yet very imperfectly known, though the peculiarities of their anatomy warrant us in supposing that they have a similar power of living out of water.

(Trans. Linn. Soc. 1850. vol. iii.; and Cuvier and Valenciennes, Hist. Nat. des Poissons, tom. vii.)

ANABATHRA, a fossil bee, from Allenbeck, Berwickshire. Described and figured by Mr. Witham, and figured in Foss. Veg. t. 8 and t. 10.

ANABLEPS, (from αναβαίνω, to look up), a genus of Malacopterygious Oseous fishes, remarkable for the curious double, or, to be more correct, quadruple eyes, which, in a few genera, are so placed, that of the irides and cornea by transverse ligaments, have two pupils, and appear as if double, whilst there is only one crystalline humour, one vitreous humour, and one retina. There is no other example known of such a modification of structure among the fishes. This peculiarity of the Anables has given rise to several stories of four-eyed fish, with exaggerated accounts of their habits. The Anabipes tetraphthalmus inhabits the rivers of Guiana and Surinam. Its body is cylindrical, and covered with strong scales; its head is flattened, and mottl. The upper jaw projects; its eyes are large, and give the fish the appearance of having two eyes, instead of one. Its anotomv has been made the subject of a memoir by Lescé-péde, which is published in the second volume of the Mémoires de l'Institut.

A NAMIBÉRTHENEIS (αναμβρέθηνεις, a remodelling or change of form) is such a representation of an object that, except when viewed from a part of point directly, or in a cylindrical mirror, or through a polyhedral lens, it will appear to be distorted, or disconnected, or to be a view of something very different from the original. Such representations are only made for the amusement of young persons, and therefore a very brief explanation of them may suffice; but the art of forming them has been treated at length in the "Thaumat-urgen Optics" of Nicerno, and in the "Perspective Horaria" of Maigram.

Distorted figures which are to appear, when viewed directly from a given point, in the joints proportions which they have in an original drawing or print, may be easily traced in the following manner:—The original being covered with a net-work of squares within a square drawn about the whole; upon any convenient part of a sheet of paper a line is to be drawn equal in length to the base of the circumscribing square, and divided into a like number of equal parts; then, from a point taken at pleasure vertically under the assumed place of the eye, lines are to be drawn of indefinite length through the points of division, to represent those which, on the original, have been drawn perpendicularly to the base or ground-line. Let next a line be drawn from the assumed spot of the eye on the paper, parallel to that which was made equal to the ground-line, and let it be made equal in length to the given height of the eye above the paper: then, if a line be drawn from the extremity of this line through one end of the divided line it meets the line drawn from the foot of the eye up to the opposite end of the same line, its intersections with all the lines which represent the perpendiculars will be points through which lines being drawn parallel to the divided line, those lines will represent the correspodence on the original parallel to the base of the circumscribing square. If, within the trapezoidal areas thus formed, the parts of the original figure which fall in the corresponding squares be drawn by another line, thus traced with the distorted figure required; and, when viewed from the assumed place of the eye, it will evidently appear exactly as, to an eye in the same point, the original would appear if it were placed in a vertical position with the base of the square on the line which
draw to represent it; that is, it will appear to be an exact copy of the original.

A distorted representation of some object, which is to appear correct on being viewed from a given point, and by reflection from a plane figure, as also given, may also be drawn on a plane by means of a perspective representation, as already described, of the squares drawn within a square circumscribing the original print or drawing. This plane must be transformed, in two different ways: in the first, by the cylindrical mirror; and from the centre of the mirror's curvature, on paper, lines must be drawn through the points of division in the chord to meet the circular arc representing the base of the cylinder; then from the points of meeting lines, squares are to be drawn equal to those which are made with them by lines drawn to the points in the arc from the seat of the eye; and on them to be set, from the points in the arc, distances equal to those of the same points from the several lines which in the projected trapezoid before described, represent the horizontal lines drawn over the original figure. Lastly, curve lines, which are nearly arcs of concentric circles, being drawn through the points thus found, there will be formed a network of mixed-lined trapezoids, within which the parts of the original figure are to be traced so as to correspond to those within the squares first drawn. This distorted tracing being laid horizontally on a table, and the mirror being set up vertically on the arc which keeps, in this instance, the same image will, to the eye, appear exactly similar to the original figure.

Distorted figures, which are to be so corrected when viewed through a polyhedral lens or multiplying glass, a lens of the same order, one of the nodal points of which is given, by a number of planes having for example the figures of triangles, may be traced mechanically thus:—Let the multiplying glass be placed in a tube, like the eye-piece of a telescope, at a distance from the end to which it is to be applied rather greater than the focal length of the glass, and let a very small aperture be formed in the cover at that end; then, on placing a lamp or candle before the aperture, the rays of light passing through the faces of the lens will project, or rather bend, so as to correspond to the faces of the images; this image will, to the eye, appear exactly similar to the original figure.

The portions thus drawn, when viewed in any manner encompassed by the object represented; and the intervals may be filled up with any objects at pleasure, so that the whole may appear confused, or may represent something different from the original landscape or figure: then, on covering the same with a sheet of paper and making small cuts, or indentures before mentioned, and the objects drawn on them, will be visible; and there will appear only the representation of the object formed by the junction of the parts within the outlines from which it is a correct copy of the original object.

ANAMORPHOSIS. (Botany.) (Metamorphous, P.C.)

ANANCHYTES (Lamarck), a fossil genus of Echinoderms, found in the chalk formations abundantly.

ANARRHICHAS, a genus of Acanthorhynchous Osseous fishes, established by Lesson, which is retained by subsequent ichthyologists. They are very nearly allied to the Bliennies; so that Cuvier remarked they might be regarded as Bliennies without ventral fins. They have round, smooth, blunt heads; elongated bodies, covered by minute scales; a single long dorsal, and an extended anal fin, both separated from the caudal; no ventrals; the mouth armed with formidable teeth of two kinds, conical incisors and flat grinders. One species, the wolffish, sea-cat, or cat-fish, Anarrhichas lupus of Linnaeus, is common off the coast of New Brunswick, Nova Scotia, and on the east coast of Scotland and the Orkneys, though rare on the English shores. Its range extends to Greenland. It grows to the length of six feet, and is a ferocious and formidable destroyer of the nuts of fishermen; when caught it defends itself with the most fearful, hissing, and snarling sounds, by means of its powerful teeth and jaws. It lives chiefly on crustaceans and tenebrous molluscs, and, like most fish which subsist on such food, its flesh is excellent eating; though, from the very great size, and narrow definition of their range, they would not be likely to be seen by any one, should he chance to visit the Edinburgh market, where, by naturalists especially, whose knowledge of its good qualities enables them to vanquish their prejudices against its aspect, it is much esteemed.

The cat-fish is of a light grey colour marked with seven or eight broad vertical bands of bluish grey. When old it becomes darker; its skin is covered with thorns. The formula of its fin-rays is—D. 22; A. 20; P. 20; C. 16. It is a very fine fish, and is one of the principal objects of this sea seen Yarrell's British Fishes, vol. i.; Pennant; and Bloch.

ANATOLIA. Since the publication of the first volume of P. C., the interior of this country has been explored by nearly all the directions, by travellers who were protected and aided by firms of the sultan. The present article proposes to give a succinct account of the geographical results of their researches. A complete map of the country, united the results of their researches and corrected and corrected: the map drawn by Arrowsmith for Hamilton's 'Researches' is the best we have, though it is only fragmentary.

The charts of the Russian Survey of the coast of the Black Sea, published in 1840 and following years, are not surpassed by any other. The survey of the western coast has been completed under the superintendence of Captain Graves, but the charts are yet unpublished; this survey, with that of Captain Beaufort of the southern coast, complete the survey of the Mediterranean coast of Asia Minor. The part of Captain Graves' survey comprehending the Gulf of Smyrna and the adjacent coast was first published in Arrowsmith's map, which accompanies the 'Researches' of Hamilton. The part of this recent survey which is erroneous. The coast of Lycia has been known since the survey of Captain Beaufort, but the interior was first visited and described by Fellows.

The principal objects of the present article are to give a correct account of the interior of Anatolia; to separate the several languages spoken in this country; and to limit as much as possible the number of terms.
as the southernmost part of a series of long narrow passes between the sea and the steep rocks of Mount Amanus; it begins, therefore, to lose the characteristic features of a mountain defile, and thence runs up to Beilâ, where it re-assumes its original character. North of Bâya the defile ceases where the plain of last begins; but farther north the narrower river bed, and after running round the innermost corner of the Gulf of Iskâderûn, enters another defile in the chain of Dûrdûn-Dagh, the northern part of Mount Amanus. The whole of these passes were called by the ancients the Syrian gates (Fylae Syriacae), because on the historian of the Persian war from Alexander and Darius down to the present time. The narrowest part of the pass across the Dûrdûn-Dagh is shut up by an ancient stone-built wall of polygonal masses of basalt, without capping, and is traversed by the road which has the Turkish name of Demir-Kûpur, or the iron-gate. Ainsworth, who has written a memoir on the subject, identifies this old fortification with the Amanian gates (Fylae Amânaides) of the ancients. The river Jîthûn, the ancient Pyramus, runs along the northern and western slopes of the range of Dûrdûn-Dagh.

The principal chain of the Taurus stretches from the environs of Merîshâ in a western direction across the whole length of the peninsula, and is generally parallel with the coast. We add a few particulars to its description in the P. C. In about 35° E. long. the chain is called Bûlgûh-Dagh, a very lofty range, through which the Jîthûn, the ancient Sirûs, passes in a bed overhanging on both sides a depth of 8000 feet height; it branches out of Gökebûlgûh-Dagh, known to the Romans as the Porta Ciliciae. During the time that Syria and the pashalîk of A'dâna belonged to Mehemedd 'Ali, pasha of Egypt, the Gökebûlgûh was partly in possession of the Turks, and partly of the Egyptians, both of whom had erected strong fortifications for the defence of their respective portions. The narrow tract between the Bûlgûh-Dagh and the coast has an alpine character, and under the meridian of Mesculli, the principal chain of the mountains approaches the coast so closely as to become visible from the sea in all its outlines. The whole country round the Gulf of Iskâderûn is thus surrounded on one side by the sea, and on the others by lofty mountains, which, from the few long and narrow defiles, may be successfully defended by a handful of men against the most numerous armies. The tract abounds in fruit, wine, corn, timber, and other productions, and is watered by two navigable rivers, the Jîthûn and the Şîhûn, and many streams of less importance, among which the Teraswâ Châfî (river of Tarsus), the ancient Cydnus, is the chief. This part of Cilicia was once a most flourishing province, and there are few countries of its extent to which so many ancient and modern collectors have resorted: the town of Taurus and Mopsuestia, the cold waters of the Cydnus which endangered the life of Alexander and killed the Emperor Frederick I., and the Plain of Iasus, where Alexander defeated Darius. If any power that is master of the sea should hereafter have the power of giving a firm foundation on the continent of Asia Minor, with the view of either preventing its conquest by an enemy of Turkey, or having its share in the dismemberment of the Ottoman empire, that power would most certainly plant its standard on the Plain of Iasus.

On following the Taurus in its western direction, we find the Karû-Dagh and the Allah-Dagh, two lofty peaks which are situated only a little distance from each other, and north of the great chain, in the southern corner of the ancient Lycia, the part of the Taurus over which the Mr. Hamilton states. The Karû-Dagh, an insulated trachytic cone, rises above a sandy plain, and is of barren and dreary appearance; a low ridge stretches from it north-east in the direction of Mount Artesius and Mount Arpasîs, with which it appears to be connected, forming part of the sand system of elevation, and standing consequently on the edge of the great table-land of which we shall speak hereafter. The Allah-Dagh stands on a base of thin-bedded semi-crystalline limestone; it is of more of the same character as the history of the Taurus, which here chiefly consists of Juras limestone. The Allah-Dagh is the summit of a lower range which runs west, and is parallel to the Taurus. The whole of the Taurus, from the Allah-Dagh west as far as Mount Arpasîs (Mount Cudamus) in 29° E. long. has not yet been explored, but parts of its snowy chain have been traversed by a few travellers, or seen from the sea in the Gulf of Adâla. The Balûch-Dagh, or most western part of the Taurus, contains its original western direction under several names, and forms the watershed between the Mendere, the ancient Ma- ther, in the north, and the Dilûmûn-Dagh, or smaller rivers which flow into the sea of Rhodes, the Gulf of Cos, and the Gulf of Mâdelîe. The whole tract which lies between the range of the Taurus and the coast of Asia Minor, or within the width of which the plains more on the curves of the coast than on those of the mountain range, has an alpine character, though the mountains are not so high as the Alps of Tyrol or Switzerland. It resembles the parts of Hâdjan, Yemen, and Hadhramût, which lie between the coast and the Red Sea, covered with the most barren tracts and deserts. Lycia is an independent part of the tract, though distinguished by the same general outlines. In its northern limits are formed by the principal range of the Taurus, and its western portion is connected with each other by transverse chains as to form a separate mountain system. The eastern part of it is a table-land, but the western part is traversed in its whole length from north to south by the Xanûth, now Erechen-Châfî, of the course of which we knew nothing till we became acquainted with it through the discoveries of Fellows.
chose that the height of Mount Arjish is 13,000 feet, a side more or less, above the sea. Ainsworth calculates it about 1000 feet lower. Strabo observes (p. 538 Cas.) that Mount Argaeus was covered with eternal snows, but his statement that both the Euxine and the Mediterranean, including the sea of Arinach and Mount Arjish, and Mount Allah-Dagh, which lies about 30 miles south of it, are the two westernmost promontories of the Anti-Taurus properly speaking, the principal chain of which is the Allah-Dagh, according to its north-east, and its summit of Mount Arjish becomes gradually higher, forms the peaks of Hasan-Dagh and Karajah-Dagh, and is connected with the Taurus by the Karaj-Dagh and the southern Allah-Dagh mentioned above. The Anti-Taurus has three chains in the north-west, the Anti-Taurus and its southern branches in the north and east, and the Taurus in the south around the easternmost portion of the great table-land, and form an extensive basin, part of which is called the plain of Karaj-Dagh. The eastern part of this basin is known to us; in the middle part are the sources of the Shihan, which flows south and traverses the Taurus as stated above; and the western part is a depression of the table-land which has no visible outlet for its waters, the greater portion of which is absorbed by the Askul, a lake of considerable extent. A small stream, which after the melting of the snow increases to a great body of water, flows out of the southern corner of this lake into a deep circular pool, 30 or 60 feet lower, and subsequently dries up. To this lake the additional water of this pool is about one-eighth of a mile in circumference, and has no outlet, nor does any stream emerge out of the southern shore of the sides, of which Hamilton concludes that the water, which he saw passes through the limestone, and reappears on the southern side of the Taurus, traversing Cicilia and flowing into the sea.

From the ridge between Arjish-Dagh and Allah-Dagh in the Taurus several chains stretch out in a western direction. The first, as we proceed from north to south, is a continuation of Arjish-Dagh, and runs under the names of Chessile-Dagh, Kesh-Dagh, Pascha-Dagh, Kari-Dagh, Ursh-Dagh, and Emish-Dagh, at first west, and afterwards north-west, till it joins the Anti-Taurus near the summit of Koj-Hisar, from which the western sides flow into the Irakirmak. The second stretches out from the range between the Hassan-Dagh and the Karaj-Dagh, perhaps from the latter mountain, north-west as far as Mount Emir-Dagh in 38° 46' N. lat., 31° 20' E. long., and thence west to the Moud-Dagh (the ancient Mount Dyomedes), where it divides into different branches which enclose valleys through which the water flows into the Arpagela. The great rivers Menderse (Masander) and Koj-Hisar, which belong to the sum of the north-western mountain. The first and second chains surround another much larger basin, forming likewise a depression of the high table-land, of which the greater portion seems to have no outlet; its eastern part has certainly none, its waters being received into the sea; and the western part is almost surrounded by mountains, and the elevated ridge of the table-land west in the east, there is another basin, the largest of all, which seems to be subdivided into several smaller basins by transverse ridges. This basin contains most of the great mountain. It is a still unknown basin.

The group of lakes in this basin forms one of the most salting features of the table-land; they may be divided into two classes, the salt lakes in the east, and the fresh-water (pamuk-kul) lakes in the west. The former are the runs of the Tuz-Gol is the largest, and of great extent; the others, such as the lakes of Tamsy, Kupack-Gol, Murud-ist-Gol, most of which lie in its immediate neighbourhood, cannot be compared to it. The Tuz-Gol was visited by Hamilton and Ainsworth. A point situated in 38° 42' N. lat. and 33° 25' E. long., lies about in its centre; its direction is south-east to north-west and north; it is about 45 English miles in length; its extreme width is about 18 miles, but its northern extremity is much narrower, and connected with the main lake by a channel five or six miles broad. A ruined causeway connects the opposite banks; it is covered with a thick coat of salt lying from the bottom to the water’s surface. The water has an overflow, which, when low it is quite dry. The banks are flat, the environs barren and covered with saline plants; along its eastern side extensive salt marshes stretch from north-west to south-east, and south-east to north-west, inclosed by impenetrable marshes partly covered with saline incarnations. The lake yields much salt, which is easily obtained, although the state of saturation of the water, which, at a very high in the spring, diminishes in the wet season, owing to several little rivers and streams which overspill themselves into the lake. When Hamilton examined the water, in July, it was completely saturated, but it was less salt when Ainsworth saw it in April. Hamilton brought some of it to this country, where it was examined by Mr. Phillips of the Museum of Economic Geology, who gives the following account of the analysis:—"Its specific gravity is nearly 1.2396, but as a few crystals of common salt had separated, either by cold or evaporation, its specific gravity may be considered as equal to 1.24. It contains 32° 2' c. of saline matter, consisting chiefly of common salt, but mixed with a considerable quantity of sulphate of magnesia and chloride of magnesium, with a little sulphate of lime and a trace of bromine, but no chlorides. The water is therefore comparable to that of the Dead Sea. The amount of saline matter contained in the water of the Dead Sea, hitherto considered the heaviest, has been calculated by Dr. Macartney to amount to 37° 1' c. The amount of saline matter contained in the water of the Dead Sea, is, according to the same authority, only 24° 5'. Traces of volcanic action abound in the environs. Another circumstance of great interest is the apparent connection between the lakes and the red sandstone and the red desert, near the hamlet of Koj-Hisar, a small town on the eastern side of the lake near the causeway, with the same formation in Pontus, from which one might conclude that the red sandstone formation between the lakes, the sandstone and rock-salt by Yez-Gatt and Aangors, which themselves belong to the system of Pontus. A mass of grey granite protrudes through the red and brown sandstone near Koj-Hisar, sending forth numerous small vies into the adjacent rock, thus proving that the formation of the great mass is posterior to that of the sandstone. Beds of white saccharine gypsum, or alabaster, are seen in the brown sandstone underlying the horizontal limestone. The lakes begins with the Askul in the south-east, which has been mentioned in the descriptions of the first basin of the table-land. It is about seven miles long by three wide. West of it, in the third and largest basin, we first met with the Soghla, the ancient Troglia, in 35° 45' N. lat. and 31° 45' E. long., another extensive lake, 20 miles long and six wide, and the lake of Bei-Sheher, the Caralita Pusgusa of the Byzantines, in 37° 40' N. lat. and 31° 50' E. long., a magnificent sheet of water which extends above 20 miles from south-west to north-west, and is from four to seven miles wide. On its western side the rocks rise abruptly from the water’s edge. The two lakes are separated by a lofty ridge of limestone mountains, through which the Bei-Sheher, the outlet of the Askul, and the Bei-Sheher lake, has a narrow channel. This river empties itself into the Soghla lake, which has no outlet, and is consequently the deepest part of this basin. North-west of the lake of Bei-Sheher are the lakes of Egerdir and Hizizar, one lake, which in the map it is called Hizizar, and the southern Egerdir. The narrow channel by which they are united lies in 28° 8' N. lat. and 31° 30' E. long. Their combined length is about 30 miles, and width of them is about 6 miles. Their waters are full of fish, and surrounded by steep and wooded hills, intersected by picturesque valleys and well-cultivated plains. Hamilton compares their appearance with that of the lakes in Italy. North of them are the lakes of Ask-Sheher and Chai-Kul, already mentioned. The lake of Ask-Sheher has a southern outlet, a deep, clear, and rapid river, the further course of which is not known. The question as to the course of its waters is of high geographical importance. It only flows south the river, which, after passing through the country, will be barred by the great chain of the Turan; and although it is possible, but not probable, that it forces itself an open passage through that range, and reaches the Gulf of
Adala, it is as likely that it escapes through the limestone of the Taurus, and, after a subterranean course of considerable length, reappears on its southern foot as a new river. If not, the case is similar to the three lakes of the Bel-Sheher, which empties itself into the lake Sohla, we see a small lake with no visible outlet, although it is fed by the waters of two very large lakes, and perhaps those of the whole southern coast of Asia Minor. It is not likely that the volume of water thus evaporated from a comparatively small surface, we should in this case also be led to believe that the water of the lake Sohla escapes through some cataract, and makes a subterranean passage through the Taurus, which Hamilton supposes to be the lake Ak-Gol, which is certainly close to it.

If we consider the most prominent features of the great table-land of Asia Minor, the great number of extinct volcanos, the masses of basalt and other volcanic productions, the immeasurable basaltic conic which are spread in all directions on that plateau, the granite which protrudes through the overlying beds of limestone, and finally the salt lakes, and an extensive tract covered with salt marshes, we are inclined to believe that the whole was once an inland sea, like the Caspian and the Aral, filled with brackish water, and that the bottom of that sea was raised by volcanic action, whereupon the waters poured forth in all directions; and on their descent to the surrounding seas digged those deep valleys which now form the foundation of the peninsulas and western head in straight lines from the ridge, or exterior parts of the table-land, down to the Mediterranean, the Archipelago, and the Sea of Marmora. The diminished volume of the remaining waters might then have been absorbed, or, to give a more subterranean notion, the whole tract may have been raised to that state in which it is now. The great quantity of fresh-water shells found on the hills of the plateau is an objection to supposing it to have once been a perfect salt sea. It was either all brackish, or divided into several large lakes, some fresh water and some brackish. It would be important to know, if among the fresh-water shells there are many belonging to such shells as live indifferently in fresh and brackish water. It will not be very difficult to explain the plateau, the rivers flowing into the Black Sea are not in straight lines. If the origin of the table-land should ever be satisfactorily shown to be what it is here conjectured to be, the peninsula of Asia Minor would no longer be considered a continuation of Armenia and Kurdistan, for the connexion between the mountain systems of those countries and the Taurus, the Anti-Taurus, and the Pontic mountains, is no obstacle to this conjecture; and as the great ranges which stretch through the country from east to west would in that case, with the exception of the Anti-Taurus, be divided into three parallel ranges, the eastern mountain-knot, and the outskirts along the three seas. But as long as these matters are merely hypothetical we must be faithful to the common notion, and suppose that the great ranges which stretch across the country from east to west, and of which we now proceed to describe the third.

3. The Euxine range.—The country between the Anti-Taurus and the Black Sea is the land of mountains, and up with mountains, the centre of which seems to be in the southern part between the Gdtr-Dagh, the Almali-Dagh, and the Gjijk-Dagh, whence several chains stretch to the west and north; others stretching eastward connect these mountains with those of Armenia. We shall call this group, which has no general name, the Lazian group, from the Lazes, a warlike nation of Caucasian origin, known in history from early times down to the present day, and whose original home must be considered the eastern slope of these chains. The Lazian group, the third landmark of Asia Minor towards the east, is the watershed between the Euphrates, which flows into the Persian Gulf, and such of the rivers emptying themselves into the Black Sea as are situated east of the mouth of the lower Aras river. On the northern side of the Black Sea the Lazian group are the sources of the Chourk-Sid, a river about 150 miles long, which flows east and north till it reaches the Black Sea near Batum: its whole course is beyond the limits of this work. The second group is the mountainous coast of the Razim-Irmak, and may be considered the natural boundary of Asia Minor on this side. The eastern limits of Asia Minor are generally identified with an imaginary line stretching from the corner of the Gulf of Isskenderun, due north-east, as far as a point situated some distance east of Trebizond. A good map will show that this line corresponds exactly with the line of the Anti-Taurus, the Taurus, and the Lazian mountains. Among the different ranges which detach themselves from the Lazian group, we shall first mention that long chain, or, more correctly, series of sub-parallel chains, which stretches in a generally easterly direction parallel with the coast of the Black Sea. These chains are known under several names. Between Trebizond and the mouth of the Yessil-Irmak we find the Mason-Dagh; and between that river and the Kisir-Irmak the Neimah-Irmak valley, the Anti-Taurus, and the Lazian mountains. They are surmounted by lofty peaks, which are however not lower than those of the Taurus and Anti-Taurus. The whole tract is a plateau, being the first terrace on coming from the Black Sea, and generally of a level surface, although it is above 1500 feet above the level of the plateau. Towards the west the plateau is broken into numerous ridges and deep valleys, the beauty of which is highly praised by travellers, and the picturesque character of the scenery is most striking in the neighbourhood of the town of Trebizond.

We come now to the district west of the Kisir-Irmak, from the point where it breaks through the chain of the Adda-Dagh. The Ilkik-Dagh, with a mean elevation of 4000 feet over the sea, abounds with forests and ranges of mountains. South of the Ilkik Dagh is a plateau of the same description surmounted by ridges of about 3200 feet elevation. South of these plateaus lies the Alkii-Dagh, the summit of which was found covered with snow, and in front of which there is a range, and north of them are others mentioned under the name of the Anti-Taurus, and others which were not named. In 41° 26' N. lat. 38° E. long. is the plateau of Ifinli, which begins in the south near the town of Zafarin-Boli, with several projectors which terminate abruptly with steep ascents, on which high rock-terraces tower one above another. On the east the plateau there are many ranges, partly bare and partly wooded, and large tracts are covered with fragments of rock. West of this plateau, and divided from it by the river Ori, is Mount Durnah-Yal-Si, the ancient Mont Doinam, which has a route of about 9 miles, and a bare crest at least 3000 feet high. Limestone and basaltic rocks abound in both of these mountains. Mount Durnah-Yal-Si is connected with the Boli-Dagh and the Karin-Ali by the Sarki-Yal-Si and the Yalik-Dagh (Mons Hyginus) in the north, and the Karin-Dagh, the Owal-Dagh, and the Kemptik-Dagh, in the north. West of the Karin-Ali-Dagh is the Gok-Dagh, or Bithynian Olympus, and between them lies the Zakaryeb or Sangerina. The Gok-Dagh is only a northern continuation of the Anti-Taurus; the eastern mountains of Mount Olympos, its western projections stretch through Mytilene and terminate in the promontories of the sea of Marmora, de Heilapont, and the Archipelago.

Hence we come to the next series of the northern chains which begin in the east with the Lazian group, we proceed to give a sketch of the mountain tract between these chains in the north and the great table-land in the south. From the junction of the western chains of the Lazian mountain with the Karin-Bel, which have already described as a northern continuation of the Anti-Taurus, some ranges stretch west, which the natives call Gemin-Beli-Dagh, and Kojeg-Dagh. They are generally parallel with the 40th degree of E. lat., and their western continuation is the Almali-Dagh. They rise above a high table-land, which is generally a level plain, and form the watershed between the Yessil-Irmak in the north, and the Kisir-Irmak in the south. A large mountainous tract lies to the west and is encompassed on the west by the Ilkik-Dagh, on the east by the Kojeg-Dagh, of which we know very little. It is a table-land, the edges of which, towards the Kisir-Irmak, are intersected by deep valleys and ravines, and form a long sharply indented wall of rocks of the grandest beauty. Across the crest of the Kojeg-Irmak, from the 38th degree of E. long., we first see the Ak-Dagh right opposite the snowy peak of the Arpaj-Dagh, stretching west. Where the Kojeg-Irmak again comes to the coast, the edge of the table-land is called Alikjik-Dagh; farther east, in the same direction is the Hasan-Irmak, a bare sharp two-headed peak, and still farther on the Boli-Dagh, a lofty chain rising high above a table-land more than 5000 feet high, and covered with snow and ice. Above Alar-Suban it forms a long promontory of the sea, rising together a sierra-like aspect. North of the Hasan-Irmak is the fine plain of Sogher, and north of it lies the Begvi-Dagh, an extensive granitic district, composed of low,
rounded, whitish, and bare hills, broken up by deep ravines, and covered with a scanty vegetation. The northern edge of the table-land, surrounded by the Kizil-Irmak River at Tokat in 40° 17' N. lat. and 36° 50' E. long., with a chain of high limestone hills surmounted by steep and craggy pinnacle, which laves the table-land near its source, and which, however, is at a considerable distance from the left bank of the Tokat-St. At Tokharl the chain is again high, and presents several steep cones. Thence to Zilleh, west and south-west, and thence north to Amasia is a high table-land, partly fertile, partly a barren place, composed of limestone, and without a trace of water. The craggy edges of this plateau towards the Tokat-St. rise to a great height above the valley and are broken by deep ravines. The rocks near Amasia are highly picturesque, and the whole southern edge of this flat place has been verified by modern travellers. From Amasia to the east range, consisting chiefly of volcanic sand or peperite, occasionally studded, runs west, partly bordering the plain west of Amasia; 18 miles west of this town theul rises into huge masses of rocks. From Chörum the table-land has the same character, being partly a level plain and partly a hilly tract, which to the north of that town is bordered by the Kirk-Delim mountains, which may be considered as the most remarkable of the barrier, and is interrupted by steep crags. Chörum south-west as far as the Bogrek-Dagh described above, is little known; its edge towards the Kizil-Irmak is more craggy and deeply cut than the side of the table-land towards the Tokat-St., except the immediate environs of Tokharl, where it has been estimated that at no great distance from the Kizil-Irmak, are the rock-salt mines of Châyán-Kö, situated in a rugged ridge of hills of red sandstone conglomerate. The surrounding country consists of the Süm a great table-land, consisting of red marls and gravel of a grey or bluish colour, the very counterpart of the suffrutescent districts of England. South of Chörum, towards the interior of the table-land, there is a succession of winding valleys sunk below the level of the plateau, and lying between white rock, varying much in colour and consistency. The high plain has a barren aspect. Towards Yüz-gatt, south of Chörum, there are deep ravines, and many broken rocks, which amidst protruding masses of clay, and other loose formations, leave large plains of some considerable extent, which have cultivated the country. The waters flow north-westward amongst the Tokat-St., a fact which proves that the slope of the table-land is towards the north. A little north of Yüz-gatt is the Halak-Tepe, a lofty hill, and the central culminating point of the tract whence rises radite in all directions: some of them consist of coarse sandstone, passing into a loose conglomerate containing pebbles of blue crystalline limestone, secondary limestone, jasper, sandstone, and sand. At a considerable distance from Yüz-gatt, and at a considerable distance, there is a range of mountains called Chichek-Dagh, which seems to be the edge of the second terrace of the table-land, on ascending it from the west, the first being formed by the Bogrek-Dagh and the Kizil-Irmak, and between these hills and fragments of chains beyond Alpgöra is another elevated table-land, but broken by deep valleys and ravines, through which the Kizil-Irmak and the Zâkîryeh with its tributaries have forced their way, and has in many places an alpine character. Many plateaus consist of trap-pan and granitic rocks, upon which the red sandstone appears to have been deposited as in a basin. Limestone occurs everywhere with masses of travertine formation overlying it. On the plateaus there are some lofty peaks and meridional ridges, and high cones of volcanic origin bear evidence that this part of the country has been reduced to its present state by the action of fire, and that the work was completed by the Kizil-Irmak in its present stage of great rapidity and magnitude, but the valleys are fertile, and yield corn, wine, and fruit of every description. Among the chains that stretch in all directions are the Ardîj-Dagh, south of A'ngora, about 3600 feet high; the Karab-Dagh, south-east of the Tokat; the Mârûn-Dagh, north-east of the Tokat-Köy-Dagh and Ishak-Dagh, which form one or perhaps more parallel ranges interrupted by table-lands which begin about 20 miles west of A'ngora and stretch in a north-eastern direc- tion for, with 100 miles, at least of the hills is formed in an immense number of basaltic prisms of great regularity of form, some vertically disposed, others horizontally. Above these, masses of a similar character tower up in rocky pinnacles of fantastic shape, in which the colossal prisms are vertically disposed. This moody distribution of basaltic prisms, says Ainsworth, supersedes anything at the Giants' Causeway, Fairford, or the Cave of Frag, and most remark- able sketches that have been published of the volcanic scenery of the islands of St. Helena and Ascension. In the northernmost corner of these mountains, in the valley of the Kerimis- köy-Dagh, there are great thickness of black basaltic lava, near its sources, and at a considerable distance from the left bank of the Tokat-St. At Tokharl the chain is again high, and presents several steep cones. Thence to Zilleh, west and south-west, and thence north to Amasia is a high table-land, partly fertile, partly a barren place, composed of limestone, and without a trace of water. The craggy edges of this plateau towards the Tokat-St. rise to a great height above the valley and are broken by deep ravines. The rocks near Amasia are highly picturesque, and the whole southern edge of this flat place has been verified by modern travellers. From Amasia to the east range, consisting chiefly of volcanic sand or peperite, occasionally studded, runs west, partly bordering the plain west of Amasia; 18 miles west of this town theul rises into huge masses of rocks. From Chörum the table-land has the same character, being partly a level plain and partly a hilly tract, which to the north of that town is bordered by the Kirk-Delim mountains, which may be considered as the most remarkable of the barrier, and is interrupted by steep crags. Chörum south-west as far as the Bogrek-Dagh described above, is little known; its edge towards the Kizil-Irmak is more craggy and deeply cut than the side of the table-land towards the Tokat-St., except the immediate environs of Tokharl, where it has been estimated that at no great distance from the Kizil-Irmak, are the rock-salt mines of Châyán-Kö, situated in a rugged ridge of hills of red sandstone conglomerate. The surrounding country consists of the Süm a great table-land, consisting of red marls and gravel of a grey or bluish colour, the very counterpart of the suffrutescent districts of England. South of Chörum, towards the interior of the table-land, there is a succession of winding valleys sunk below the level of the plateau, and lying between white rock, varying much in colour and consistency. The high plain has a barren aspect. Towards Yüz-gatt, south of Chörum, there are deep ravines, and many broken rocks, which amidst protruding masses of clay, and other loose formations, leave large plains of some considerable extent, which have cultivated the country. The waters flow north-westward amongst the Tokat-St., a fact which proves that the slope of the table-land is towards the north. A little north of Yüz-gatt is the Halak-Tepe, a lofty hill, and the central culminating point of the tract whence rises radite in all directions: some of them consist of coarse sandstone, passing into a loose conglomerate containing pebbles of blue crystalline limestone, secondary limestone, jasper, sandstone, and sand. At a considerable distance from Yüz-gatt, and at a considerable distance, there is a range of mountains called Chichek-Dagh, which seems to be the edge of the second terrace of the table-land, on ascending it from the west, the first being formed by the Bogrek-Dagh and the Kizil-Irmak, and between these hills and fragments of chains beyond Alpgöra is another elevated table-land, but broken by deep valleys and ravines, through which the Kizil-Irmak and the Zâkîryeh with its tributaries have forced their way, and has in many places an alpine character. Many plateaus consist of trap-pan and granitic rocks, upon which the red sandstone appears to have been deposited as in a basin. Limestone occurs everywhere with masses of travertine formation overlying it. On the plateaus there are some lofty peaks and meridional ridges, and high cones of volcanic origin bear evidence that this part of the country has been reduced to its present state by the action of fire, and that the work was completed by the Kizil-Irmak in its present stage of great rapidity and magnitude, but the valleys are fertile, and yield corn, wine, and fruit of every description. Among the chains that stretch in all directions are the Ardîj-Dagh, south of A'ngora, about 3600 feet high; the Karab-Dagh, south-east of the Tokat; the Mârûn-Dagh, north-east of the Tokat-Köy-Dagh and Ishak-Dagh, which form one or perhaps more parallel ranges interrupted by table-lands which begin about 20 miles west of A'ngora and stretch in a north-eastern direc- tion for, with 100 miles, at least of the hills is formed in an immense number of basaltic prisms of great regularity of form, some vertically disposed, others horizontally. Above these, masses of a similar character tower up in rocky pinnacles of fantastic shape, in which the colossal prisms are vertically disposed. This moody distribution of basaltic
ment of volcanic products; basaltic cones rise everywhere, marble is abundant, limestone occurs generally, and in many places the table-land is undulating. This circumstance gives additional strength to the hypothesis that the central table-land was once a lake. The Mərdə-Dagh with its eastern chains, the Sultan-Dagh and the Emir-Dagh, and its western continuations the Ak-Dagh and Demili-Dagh, and their valleys and plateaus, show that the volcanic rock and metamorphic limestone, which form the table-land, are underlaid by basaltic rocks. The basin formed in this manner must have been surrounded by a high rim of basaltic cone, and the general level of the whole range was covered with snow in the month of April. The chains by which the Mərdə-Dagh is connected with the Olympus, and between which the river Eroden flows, begin in the central table-land, and its height must be considerable, as the whole range was covered with snow in the month of April. The chains by which the Mərdə-Dagh is connected with the Olympus, and between which the river Eroden flows, begin in the central table-land, and its height must be considerable, as the whole range was covered with snow in the month of April. The chains by which the Mərdə-Dagh is connected with the Olympus, and between which the river Eroden flows, begin in the central table-land, and its height must be considerable, as the whole range was covered with snow in the month of April.

The general character of the geology of the peninsula, says Hamilton, is simple. The eastern extremities consist of trachytic rocks, which towards the west are succeeded and partly replaced by black volcanic basaltic rocks containing angular fragments of trap or trachyte. The western part of the peninsula consists of calcareous rocks which seem to belong to the scaglia or cretaceous formation. All these are horizontal, and the lower portion is a hard compact scaglia like that of Greece and the Ionian islands. This (the lower, hard portion) contains no fossils, but is overlaid by beds thirty or forty feet thick containing a great variety of shells, amongst which are Caribula and Modiolus. The beds vary considerably in hardness and some are rather soft and others more compact. Near the summit of the hill are the ancient quarries, in which lie large blocks hewn and ready to be removed. The same writer says that he could not find the line of junction between the limestone and the trachyte, so as to form any conjecture of their relative ages.

Hydrography—1. Rivers. Our knowledge of the rivers and lakes of the peninsula has been greatly extended by the discoveries of recent travellers. In enumerating them we proceed from the gulf of Dündar-dın east along the coast of the Mediterranean, &c. The Jhun (Pyramus) has its sources near Mərsəh in the eastern beginning of the Taurus, in 57° 35' N. lat., 36° 59' E. long., flows south-west for about fifty geographical miles, and is then superseded by the Dündar-dın, which flows west from the Dündar-dın, turns south and south-west, pursuing that course for about 35 miles, and taking a sudden turn towards east, falls into the small bay of Ayı. Its annual floods rise from the point where it turns east to south-west, and are caused by a great scale, of which it is the principal part, and extends along the coast from near Cape Kard-Tash at the entrance of the gulf. Its whole length is about 100 miles; it receives on its right the Sədirun, which descends from the Taurus. Its upper part is confined between steep rocks; it reaches the plain of Alexander in 52° 30' N. lat., but the hills of the Dündar-dın accompany it in the east as far down as Mount Misia. The lower part of the Jhun is navigable. The sources of the Səhun, the ancient Saurun, are in the central table-land, in 56° 12' N. lat., 34° 23' E. long.; its course is about 50 geographical miles, and is then superseded by the Cilician defiles of the Taurus, and 40 geographical miles south-west till it reaches the gulf of Lycia in 36° 44' N. lat., 34° 59' E. long. It enters the plain of Caria, and is much changed in its lower course. Its whole length is about 50 geographical miles. The whole course of the Səhun and the Jhun is not known.

The Tercit-Chañ, the ancient Cydnus, a small river, originates near the entrance of the Tercit-Chañ, and is a plateau of 3800 feet elevation, and after a south-south-east and south-west course of 40 geographical miles, which is only partly known, empties itself in the sea a little west of the mouth of the Jhun. The Gık-Şu (Calycodnus) has its sources in the Taurus, in 37° N. lat., 33° 36' E. long.; it drains the western part of Chicia, and after a south-eastern course of about 50 miles has joined the mountainous tract, joins one sea a little above Selwék, the ancient Seleucia. Among the rivers mentioned by the ancients in Pamphylia are the Eurymedon, the Cestrus, and the Cataractes. The maps do not give the present name of the Eurymedon, but the river that passes through the country of the Lycian is the noble river; the Cestrus is the present Akaï, and the Cata-

The description of this river will be appropriately accompanied with a few remarks on Lycia, one of the most interesting parts of the peninsula, and unknown to Europeans till Felziers published his account of that country. The Xanthas has its sources in the snowy ranges of the Taurus, and flows due south as far as Hörən, where it receives, on the left, a tributary of about 26 miles length, and much longer than the portion of the main stream above that point. From Hörən the river runs through a border of limestone hills and picturesque rocks in a south direction with a slight western inclination; and a little below the ruins of the ancient city of Xanthus it turns abruptly west and falls into the sea, after a course of about 50 miles. Below Hörən it is crossed by a series of cascades, the highest of which is over 150 feet, and between this bridge and the bay of Makri (Glaucus) in the west, the river Xanthus and the sea, is filled up by sand-bars known by the ancient names of Cragus and Anti-Cra-

The length and breadth of the whole country of the Lycians is about 1200, 5000, 5400, 5100, and 5000 feet respectively. The eastward continuation of the table-land is 25° west, which must be the eastern limit of the Lycian peninsula, lies between the river Xanthus, and the bay of Makri, and is a part of the ancient district of Lycia, which has been known as the best sailors among the Greeks, especially for ships of war. On this table-land there is a river that falls into a cavern and disappears. A few miles south of the cavern there is the lake of Axewel, which has no outlet, is three or four miles wide and ten long, and lies in the middle of a highly cultivated plain which is about 3000 feet high. Between the table-land and the eastern coast of Lycia is the Taktula-Dagh, the ancient Mount Solyama, with a very abrupt inclination, and towards the sea, and large table-land beyond it forms a terrace which is lower than the Taurus, but higher than the elevated tract along the southern shore. The tract along the shore is traversed from west to east by the little river Dernem, it is a smaller river than the ancient rivers of the eastern coast of the peninsula, and rises near the sea and discharges itself into it. The exterior of Lycia resembles on a small scale the northern part of the peninsula between the Black Sea and the central table-land; and the Dembre and the Xanthas are on a small scale in the south what the Yeapul and Kizil-Irmak are on a large scale in the north. In the same relation in which Lycia stands to the whole peninsula, the peninsula with its central table-land, barren rocky plains, and other and other without outlets, and longer in breadth than in length, is to the midst of the midlands, stands to all Asia, and this circumstance might not have escaped the keen eye of the later ancients, and suggested to them the name of Asia Minor or Little Asia.

The next river to the Xanthus is the Dolummon-Chañ (Cullah). Its sources are supposed to be about 57° 15' N. lat., 36° 0' E. long., in the high table-land north of the Dolum-mon-Chañ, and south of the western table-land of the Cilician part. It passes through a defile in a series of cascades, and flows in a deep ravine through a plateau 6000 feet high. Its course, which at first is east to west, soon becomes south-west, but nearly the whole of it is unknown, except the part near its mouth, a little north-west of Cape Ghina, where it turns into the sea. The Dolummon-Chañ is about 100 miles. No large river occurs between the Dolum-

* In Arrowmuth's map belonging to the Journal of Hamilton, this part of its course is north west to south east.
Maestad, has its source in 38° N. lat., 30° 20' E. long., in a chain of antient rivers—first to the east toward the Bâhâ-Dîgh, and bordering the elevated plains of Dîsdr. Hamilton states that it issues from a small lake fed by subaqueous springs, and surrounded by steep and lofty mountains. This corresponds with the account of Pîny. The source of this river, from this spot, in 38° 24' N. lat., 30° 20' E., is the scene, and in its environs is the spot in the plain where Maryas paid so dearly for his presumptuous rivalry of Apollo (Xenophon, Anabasis, 1: 2); but the cavern where Apollo hung up the head of the Thracian Cub, according to Homer's 'Iliad,' is in 2° 10', and 37° 36' 10". above the course of this river is 24 geographical miles north-west, through the high plain of Dîsdr; 16 geographical miles south-west, and 20 geographical miles north and north-west, partly through high plains, partly through a deep rocky valley; 110 geographical miles south-east, through an rugged mountains, to a beautiful valley that becomes wider and more fertile as it approaches the coast. Its whole course is above 170 geographical miles. Its tributaries are, on the right, the Sanudiki-Châf, which comes from the south-west continuation of the Mûrûd-Dîgh, and the Hânâs-Châf, 50 geographical miles long, which rises at the foot of the Mûrûd-Dîgh, and joins the Maestad where this river begins its regular west-south-west course.

The Kôpî-Sû, a smaller river, rises in the Bûn-Dîgh immediately above the Maestad. From this spot down to the coast only small streams join the Maestad on the right. On the left it is joined by the Chôrû-Sû, the antient Lycus, a small river flowing east from west; the Kârû-Sû, which flows into the Bûn-Dîgh; the Kôhû-Sû, which flows from Mount Bâhâ-Dîgh; and the Chânî-Châf, the antient Maryas, the sources of which are about 35 geographical miles south-south-east from its junction with the Maestad.

The part of the river running down between the Little Mêndere, the antient Casyter, has its source in the angle formed by the Kestânâ-Dîgh (Mosseig) in the south, and the Kâhîl-Mûsâ-Dîgh (Tmolos) in the north. It falls into the Gulf of Scula Nâsūr, after a western course of 60 geographical miles. The Kudûs or Châmû-Dîgh, another antient Hrus, has its sources in the Mûrûd-Dîgh, south-east of the town of Ghidîz; its course is 20 geographical miles west, 36 south-west, nearly 100 geographical miles in a straight line, and 130 geographical miles south-south-west, till it falls into the bay of Smyrna, which leads with its clayey and sandy deposits. In its upper part, the only river of consequence that joins it on the left is the antient Cogamus, now Allah-Sheher-Sû (2), the sources of which are only a few miles from the middle part of the Maestad, in 35° 24' E. long. It joins the Hrus after a north-west course of 50 miles, through a beautiful and highly cultivated valley.

On the right, the Hrus receives in its upper part the well-known river of the antient Greeks, the Kifwa, which comes from the Ak-Dîgh and the Demirji-Dîgh, and in its lower part it receives the Ak-Sû (Hyllus 7). The middle part of the Hrus, between the mouth of the Cogamus, and the sudden turn which it makes near its mouth to the north-west, is called the Bîkîr-Dîgh (Cahos), the Tûsîl, and the Mendere (the famous Scamander), flowing west, and the Bûkîâ-Châf (Aspesus 7), which flows north into the sea of Marmara. The only important tributary of the Hrus is the Edrenos, the antient Rhymbacus, which is formed by the junction of two rivers. One of them, the Rhymbacus or Edrenos Proper, originates in the lofty chain which connects the peaks of the Ak-Dîgh and Ak-Dîgh (Monte Vento), which after a north-west course through a beautiful valley falls into the large lake of Abulliont (Apollonias); it issues from the northern corner of this lake, and empties itself into the gulf of Miadâzâh, after a course of about 120 geographical miles. The other, the antient Marcestos, which comes from Simâlîl, at the foot of the Ak-Dîgh, where it is called Sîmâdîl-Sû; it flows west for 60 geographical miles, and north for 80, and joins the Bûkîr-Dîgh, 300 feet below. It is called the Bûkîâ-Châf (Aspesus), and the Marcestos is one of the largest branches of Abulliont. The Rhymbacus also receives the Kârû-Dîgh, the outlet of the great lake Manîfà. Until Hamilton made these rivers the subject of very careful examination we knew very little about them. Between the Rhymbacus and the Zakkaryeb there are only small rivers, the Nifûdeh or Loîf-Sû, near Brûsur, and the outlet of the lake of Inizik or Nûres 7. The Zakkaryeb, the antient Sangarius, is the second in magnitude of the rivers of the peninsula. Its sources are rivers on the high table-land between Kûthîshây and Scerînâsh, so that the river passing by Chânîd in 39° 16' N. lat., 31° 24' E. long., is the main branch; or a river which comes down from the Ermeni-Dîgh, in a northern direction, and passes by Hergân Kûleb, is the principal branch. Those two streams unite about six miles east of Chânîd, whence the river flows east and north till it is joined by the Ermeni or A'ngora-Sû, by which the mountainous tract of A'ngora is drained. The mouth of this river, on the north-east, only a few miles south of the city of A'ngora, the river has been seen by European travelers only at a few places. Its general course however is known, and in tracing it we follow a map of Bithynia, in the first volume of Le Flem's 'Atlas Historique.' The course of the Zakkaryeb will be found defective as to geographical correctness in many parts, but we may rely upon its general correctness, and with regard to its details and the names of localities; as there is perhaps no man in Europe who knows Bithynia, the original abode of Orontes of the Greek and Phrygian races, better than the celebrated Mr. Hammer.

The direction of the Zakkaryeb, from its junction with the A'ngora-Sû, as far as 33° 1' E. long., is west; thence it flows west and north-west till it reaches the north-eastern provinces of the Ermeni-Dîgh, a lofty and wooded range connected with the Olympus of Brûsâ by the Tûmânî-Dîgh. At the foot of the Ermeni-Dîgh, near Sîgûtî, a few miles west of the Zakkaryeb, stands the tomb of Óxâghrul, the father of Osman 7.

From the Ermeni-Dîgh, which is close to the stream, the river runs north, north-west, and north to the town of Sârîkàf, a village about 10 minutes south of the latitude of Nîces, the river is fordable at a place called Sûrîkûn, that is 1 ford. The most western part of the river, according to the map, is in 30° 1', but it is seen only in the above-mentioned map, as to the fact; and the curve of the river in this part varies much in different maps. In the latitude of Nîces there is a stone bridge over the river near Kiw (Kimîrî Gaîwa), and on entering the great road joining the towns of A'ngora and A'ngora unite. From that spot the direction of the Zakkaryeb is north-east, and in the latitude of Nîcema it turns suddenly east, but it soon flows north, north-west, and north, and it enters the sea in 41° 17' N. lat., 30° 42' E. long. From this point it suddenly turns east, the river runs north, and the old bed is still visible. A fine bridge of antient construction, 1087 feet in length, leads across the bed, through which a small arm of the Zakkaryeb flows north. Near this place it is joined by a bridge from the Nîces, and Kiw the Zakkaryeb flows for 13 miles through a gloomy intricate defile, with high and rugged precipices rising perpendicularly on both sides. The summits of the mountains are covered with excellent timber, oak, beech, sycamore, and ash. The Sangarius, says Kimîrî, is in general about 100 yards wide (near Kiw), contains an immense body of water, and flows with surprising rapidity. The stone bridge over it, according to an inscription, built by Sultan Bâkûr-Gûl, in 1510 (L.), was renovated in 1719, and was renewed by the current. Ainsworth crossed the river on a wooden bridge near the ancient bridge, which is over the dry bed. The width of the river was 327 feet, with an average depth of two feet, and a rate of about three miles an hour. He adds that the same river was liable to overflow in 1804 and in September, the driest month of the year. The tributaries of the Zakkaryeb, besides those mentioned above, are on its left, the Fûrâk-Sû, the antient Thymbrius, which comes from the Mûrûd-Dîgh, and after a northern and north-eastern course of about 50 geographical miles, and passing by Kûtâ-jiây and Sîkê-Sheher (Doryalemon), joins the Zakkaryeb about 10 geographical miles below this town. The Yeîlî-Sû (Yeîlî-Sû), which joins the main river near Kiw, after a north-eastern course of 50 geographical miles; it comes from the Olympus of Brûsî. A river which flows from the east falls into the Zakkaryeb on its right, below Sûrîkûn, after a westerly course of 40 miles. It has no name in the map, and its mouth is 80 feet wide. The river of the Kerims-Sû, and the Zakkaryeb may be estimated at 220 geographical miles. The distance in latitude between its mouth and the sources of the Thymbrius, which has often been taken for the main river, is about 30°; but between the mouth of the Kerims-Sû and the Zakkaryeb is about 80 miles; and consequently belongs to the upper system of the river, there is only a difference in latitude of 40'; and there are only 30° difference between it and the sources of the Kerims-Sû. The defile near Kiw is the place where traces of former canals may be seen. The Zakkaryeb descends into the Exunie plateau. The mouth of the Filîsî, the antient Biliaus, is in 41° 35' N. lat., 32° 6' E. long. Its lower part has been visited by Ainsworth, who describes it as a 'noble river' flowing through a most beautiful valley from south to north. We know nothing of its upper part.
except a portion of it near Zafaran-Buli, where there is a wooden bridge over it. This is mentioned in the first volume of Travels (p. 60), and it was also noted in the 19th-century map which accompanies Hamilton's 'Travels,' also leaves a blank for the country thus traversed by Ainsworth, and neither indicates the towns of CHERKESH and CHOMONIM visited by the traveller, nor the water-courses which are closely pressed in the north by the Durnah-Yaill-i (Mons Orminius), it turns west by Fillya, but being stopped by the Karab-Dagh it flows north along the eastern foot of this chain. The Fillya thus effects the drainage of the tract which begins between the mouths of the Zakarye and the sources of the Milian-Irmak in the west, and is bordered in the south by the range between the Bدل-Dagh and the Ishk-Dagh, and in the east by the chains between the Ishk-Dagh and the Black Sea. The waters flowing south of this border flow into the Zakarye, and east of it they are tributaries of the Kizil-Irmak.

The Kizil-Irmak (Halya) is the largest river of the peninsula. Its sources are now known: they are in the Gemin-Belli-Dagh, in 40° N. lat., 37° 40' E. long., in the northernmost part of the second of Phrygo-Cappadocian terraces. The river at first flows south, but it soon takes a south-west direction, which it pursues for about 150 geographical miles, through a picturesque valley, along the northern border of the seven east-west tablelands.

This part of its course is partly confluence. In 38° 40' N. lat., 34° 4' E. long., it turns north-west, with some western bends, and flows in that direction as far as a point in 40° N. lat., 39° 20' 30" E. long., for about 150 geographical miles. This part is likewise imperfectly known. Thence it flows north-east, east, and again north-east as far as Omsmflik, for 100 geographical miles; this part is much better known. This part of the course is shortened, and has partly been observed, to be west for about 20 and thence north-east for about 30 geographical miles, as far as the defile of Karal-Tepé, a narrow pass overhung by huge precipices. A portion of this pass is formed by an angle of the main river, and another portion by the valley of the Gok-Irmak, called here Costambuli-Chai, or Karal-Siid. From this spot the river flows south-east for 15 geographical miles, and thence north-east for about 40 miles. It empties itself into the sea by two navigable channels, in 41° 48' N. lat., 36° E. long. The sea flows north-west along the coast, and flows through a flat alluvial tract. The whole length is above 430 geographical miles: the distance in latitude between its mouth and its sources is only 1° 50'. We know of no considerable tributaries to this river except the Gok-Irmak, mentioned above, which rises in the mountains of Urmûn-Bûrûm, west of Kastamuni, which lies on its eastern bank: the Gök-Irmak has an eastern course of about 70 geographical miles, and flows along a valley bordered by high rocks, and generally fertile fields. It appears to be adapted for regular navigation by large craft; the waters are low in the dry season; but they greatly increase in winter and spring, when the snow melts on the high northern mountains, and flows in a strong stream along the valley. The Yeshil-Irmak, the last considerable river in the eastern part of the peninsula: we know little of it. Its sources are at the north-western foot of the Lætan group, in 40° N. lat., 39° 5 E. long., and it enters the Black Sea below the fortress of Chârnehâmeh, after a north-western and south-western course of about 50 miles. It receives on the left the Tökêt-Siid, the antient Thaïs, of which the sources lie between Niksar, on the Yeshil-Irmak, in the north, and the large town of Tökät in the south. Its course is west, with occasional bends to the north as far as Amasia, a distance of about 90 geographical miles, and then south to Amasia west and north-west for 30 miles. The Tökät-Siid receives on its left the Choterlek-Irmak: its sources are in the Kirk-Delnin Mountains, north of Chârnehâmeh, and enters the Yeshil-Irmak near the town of Kizil-Irmak, in 41° 2' N. lat., 38° 48' E. long.; its direction is south-east to north-west.

Lakes.—Besides those mentioned in the description of the great lakes, the lake of Aballione (Apol lonia) lies on the south-western border of Bithynia, between Mount Olympus and the Gulf of Medînisch: it stretches from east to west 20 miles, and 12 1/2 north to south. On the south it is bordered by the beautiful wooded mountains of Olympus, on the north-east by thievichy hills, and towards the north-west by marshes. The north-eastern portion is studded with many islands: one of them, which is connected with the mainland by a wooden bridge, stands near the antiens Apollonia, the antient Apollonia ad Rhynion. The town some of the islands, and the whole surrounding countries, are full of ancient ruins. The lake abounds with fish, and supplies the markets of Brissa and Constantinople. The river Ebrous is a 280 feet broad a little below the spot where it issues from the lake, and it is crossed by a wooden bridge. The lake of Nilûni, the antiens lake of Melitopolis, is west of that of Aballone, on the eastern borders of Myasia: it is 14 miles long from east to west, and 8 miles wide from north to south. The geographical and historical notices of it are not abundant; it is well cultivated, and produces much wine, which is highly esteemed by the Greeks. At Kazakli, at the western extremity of the lake, there is a Christian population, and is said to be the scene of a great battle with the Turks. The lake of Buldir (37° 45' N. lat., 30° 25' E. long.) is so called from the town of Buldir, which stands near the southern part of it: it contains five thousand acres, and has a numerous population, of which a considerable portion are Greek. The length of the lake from north-east to south-west is about 17 miles, and its width about four. The southern shore is flat, and the banks are very muddy. The neighbourhood produces much gum-tree sap, which comes from a plant (gum) resembling a species of furze. It is obtained by making an incision in the stem near the root, and cutting through the pith, when the sap exudes in a day or two, and hardens in the opening, after which it is collected by the peasants. Its price is about 10 kreutzers per inch. A lake of the same name is said to be under the Turkish name of ‘kether.' The water of the lake is blackish, with a strong taste and smell of sulphurated hydrogen gas: it is very shallow, and it is covered with thick, soft fowl. The lake contains a considerable part of the Lake Ascania by Pilny (Hist. Nat., xxxi, 10), but it cannot be the Palus Ascania of which Arrian says that its water was so salt that it crystallized naturally, and that the inhabitants felt no want of the sea, as they got salt from the lake: Arrian (Anab., ii. 1-22.) says that another lake in the neighbourhood which corresponds with the account of Arrian. This is the lake of Chârnehâmeh, about 14 miles north-west of the lake of Buldir; it is about 20 miles long from east to west, and 10 miles broad, and is surrounded by high hills, with precipitous and lofty cliffs. In summer the lake is very shallow, at least near the banks, which are muddy, but in winter the water rises. In the
by reason the water is perfectly saturated with salt, which crystallises on the surface, and is scraped off the mud with large wooden spades. The broad muddy beam along its banks is likewise covered with salt coats, and great quantities of salt are annually produced here. A species of salicornia grows near the sea, and a species of mignonette, called the Aquatic Aralia; but it is also identified with the lake mentioned by Herodotus (vii. 30) as being situated near the town of Aphanis in Phrygia, and from which salt was exported to Ashar, where it was obtained and sent to Hamilton. We omit the lake of Nicassia, though large, and the most picturesque sheet of water in the peninsula, and many others, as they have either been described under other heads, or are not important enough in a general description of the country.

Mineral Productions.—Both Hamilton and Ainsworth, who have contributed so much to our knowledge of the peninsula, had a firmain to inspect the mines, and they visited many which were hitherto unknown except to natives. Mining skill is in a very low state in this country. There are copper-mines near Bükir-Kurechâf, not far from the Black Sea, in the plateau of Åfên; near Châlswor, on the Black Sea, near Tintak, and many other places. Iron-mines near Üniçli, near Uniction, on the Black Sea; silver with copper, in the mines of Têbrezil; and silver and lead at Denek, in the Begrekk-Dagh, east of the Kizli-Urmâ. Nitre is got at Karâ-Bûnik, in the south-eastern part of the plateâls; Salt-lakes abound in all parts, especially in the north-eastern part of Asia Minor and in the tract round Ängora.

Hot springs occur in all the provinces: those of Brûcâ are celebrated, and are even visited by European patients. The hot springs near Ereğli, in the southern part of the peninsula, are much frequented, and there is one particularly which is hotter than any other in the peninsula. It issues out of narrow crevices on the summit of a ridge of low hills near that town, and forms a succession of small pools and conical hills, which have been created by the gradual deposit of the earthy matter with which the water is charged, and which forms at first small pools round each orifice, which, by the rapid evaporation of the water, are soon raised into cones. The confined water and gases are heard bubbling under ground. Some of these springs deposit potash, and others deposit sodium sulphate of lime or gypsum, which is the most frequent.

(Hamilton, li. p. 307, &c.)

Population.—A closer examination of the accounts of recent travellers leads to interesting results on this point. The opinion that a line drawn from the corner of the Gulf of Ädâla to the mouth of the Zâkârâyik would divide the country into two parts, so that in the western portion the Greeks would form the majority, and in the eastern the Turks, is not accurate. As to the towns, the proportion of the Turks to the Greeks is not more than eight to ten, and the tenth part of the population, and in Bithynia the Turks are the three times as numerous as the Greeks. The Turks are more numerous in the western part than in the east, and the towns are more numerous in the towns, and several districts in the western part are exclusively inhabited by them. All those who call themselves Turks are not of Turkish origin, and there are several hundred thousand so-called Turks who are descended from Greek ancestors. There are also Mohammedan Arminians in the east. Those among the Turks who style themselves Osmânlis are settled in the country, and lead an agricultural life, though many of them live during the summer time, when the rice and tobacco fields are in full growth, and visit the towns and market places, and some of them in the towns, and some of them in the interior of the country, and lead a life of idleness. Both are exclusively for agricultural or pastoral purposes, leaving their houses empty in the villages. The Turkomsans are most numerous in the east; but such among them as are shepherds, and lead a real nomadic life, wander as far as the table-lands of the western provinces. The Yûrûks are nomadic Turks, probably of the same origin as the Osmânlis, and are numerous in the northern, middle, and eastern parts. In the same district there is a considerable number of Kûrds, who are either pretended or real, who are the secretaries of the chief of the villages, and who are at the head of the landladies, and sometimes, though seldom, as far as Brûcâ. The Turkish peasants are a brave and honest set of men, full of confidence, faithful, trustful, ready to assist, liberal, generous, by no means so grave as the Turks are generally represented, for a people of the same nation, religion, and sentiment; they are very ignorant and credulous. Follies, perhaps, gives too favourable a description of them; but he was in the Arcadia of Asia Minor. Religious prejudices are less strong in the peninsula than in European Turkey, and generally the population of Anastasia may be considered as the best part of the whole population of the Turkish empire.

We add some of the routes of Hamilton, and some of the points of latitude computed by him:—

1. Road from Mûdîniâ to Smyrna, in distance hours:—

Mûdîniâ—Bâsh-Arûs, 6; Têbrezî, 6; Asaadî, 6; Aphanis, 6; Smyrna;—

2. From Kârakûsh to Smyrna, in distance hours:—

Kârakûsh—Buûchâ, 1; Çorhîm, 2; Chorûm, 3; Arka, 4; Heki, 5; Smyrna, 6; Aphanis, 9; 8 miles. 1

3. Smyrna to Ainsworth, in distance hours:—

Smyrna—To Tirebdli, 1; Akhsâm, 6; Smyrna;—

4. From Smyrna to Ainsworth," Travels and Researches in Asia Minor, &c.; Ainsworth, &c.; Ainsworth, 115
at least before the first receipt or possession of a body. The secretary of state appoints inspectors of places where anatomical examinations are carried on, and they make a quarterly return of every deceased person's body removed to each place in their district where anatomy is practised, distinguishing the sex, and the name and age. Executors and others (not being undertakers, &c.) may permit the body of a deceased person, legally in their possession, to undergo anatomical examination, unless, to the knowledge of such executors or others, such person shall have expressed his desire, either in writing or verbally, during the illness whereof he died, that his body might not undergo such examination; and unless the survivor, husband or wife, or any known relative of the deceased person, shall require the body to be interred without. Although a person may have directed his body after death to be examined anatomically, yet if any surviving relative objects, the body is to be interred without undergoing such examination.

(§ 6.) When a body may be lawfully removed for anatomical examination, such removal is not to take place until forty-eight hours after death, nor until twenty-four hours' notice after death to the anatomical inspector of the district of the intended removal, such notice to be accompanied by a certificate of the cause of death, signed by the physician, surgeon, or apothecary who attended during the illness whereof the deceased person died; or if not so attended, the body is to be viewed by some physician, surgeon, or apothecary after death, and who shall not be concerned in examining the body after removal. Their certificate is to be delivered with the body to the party receiving the same for examination, who within twenty-four hours must transmit the certificate to the inspector of anatomy for the same district, accompanied by a return stating at what day and hour, and from whom, the body was received, the date and place of death, the sex, and (as far as known) the name, age, and last abode of such person; and the particular, with a copy of the certificate, are also to be entered in a book, which is to be produced whenever the inspector requires. The body on being removed is to be placed in a decent coffin or shell, and be removed therein, and the party receiving it is to provide for its interim after examination in consecrated ground, or in some public burial-ground of that religious persuasion to which the person whose body was removed belonged; and a certificate of the interment is to be transmitted to the inspector of anatomy for the district within six weeks after the body was received for examination. Offences against the act may be punished with imprisonment for not less than three months, or a fine of not more than 50l.

The supply under this act, of the bodies of persons who die in places of public lodging, and elsewhere is said to be sufficient for the present wants of the teachers of anatomy; and the enormities which were formerly practised by 'resurrection-men' and 'harkurs' have ceased. The number of bodies annually supplied in London for the purposes of dissection amounts to 600.

ANCHOR. Among the changes proposed within the last ten years in the construction of anchors, the most remarkable perhaps is that brought forward by Mr. Porter, for which a patent was obtained about five years ago.

The objects designed to be attained by this new construction are said to be mainly the two following:—the avoidance of the consequences of what is termed 'fouling,' by the cable passing over the exposed fluke of the anchor when the vessel is swinging in a tide-way; and the avoidance of injury to the vessel itself, in the event of falling upon her anchor. The peculiarity of the plan consists in giving to the arms and flukes a freedom of motion, and to a pivot or pin on the lower end of the anchor, the departing at once from the rigidity usually observed in the construction of anchors. The arms and flukes are forged wholly independent of the shank, and have a hole drilled transversely through the centre, for the reception of the pivot bolt which joins them with the shank. To give a familiar illustration, the joint may be described as of that kind which connects the wires of an umbrella with the ribs, so as to give a freedom of motion round the pin or bolt as an axis. To the shank is attached one fluke, and to the ground, the other necessarily falls down upon the shank, thereby avoiding the danger incident to the upward projection of a sharp point.

A paper appeared in the 'United Service Journal' for 1840, in which the effect of this swivel action was rather minutely traced. When the anchor is dropped from the vessel, it descends swiftly and strikes against the bottom of the sea with great momentum (estimated, with an anchor of ten hundredweight and a depth of twenty-four fathoms, at 45 tons). When the anchor rests fairly on the ground, its first position a

with the lower peak, or tip, in contact with the lower surface of the shank, the upper peak being as far as possible from the shank, as shown in position A in the above figure. Then the slightest movement of the cable suffices to disturb this position, and to bring the lower peak into a direction fitted to penetrate the ground, as at B. This illustration continues until the upper peak touches the upper surface of the shank, and the lower peak is directed almost perpendicularly: a position very favourable for penetration, which then takes place. The shank and stock then lie flat on the ground, as in C; and the anchor, if pulled in the direction of the shank, has a tendency to fix itself more firmly in the ground, by keeping the lower fluke almost perpendicularly in the ground.

It is evident that the free movement of the arms on the end of the shank must produce great modifications in the position which the anchor assumes under varying circumstances; but the efficiency of the change must be determined by the daily task of practical navigation. Captain Denham, of the Marine Surveyor's Department at Fleetwood, gave a report of some experiments which he had tried in 1840 on the new swivel anchor, and states the following as the results to which he had arrived:—It is almost impossible to foul it; it glides quickly into the most stubborn ground; it holds on to the shallowest peak; it cannot lodge on its stock end; it presents no upper fluke to injure the vessel herself, or others, in shallower water; it cannot injure vessels' bows when hanging close to hill, as merchant-vehicles find a common practice which is not so likely to break off an arm, or part in the shank, as anchors with fixed flukes do, because the construction of these arms can be of continuous rod-iron, and the fulcrum of leverage is so much nearer the ring, owing to the particular of the upper fluke being placed at the shank; it is a most convenient anchor for stowing inboard on a voyage, as the flukes can be easily separated and passed into the hold; it can as easily be transported by two boats when one would be damaged by the whole weight; it produces the desired effect of ground-stable at one twentieth less weight." (Unit. Serv. Journ. March, 1840.)

In 1836 Mr. Meggett patented an anchor in which the wide flukes, or palms, are dispensed with, the flukes being very little broader than the arms; while at the same time there is an increased width given to the crown by the addition of a triangular piece of iron. The objects of these modifications in the customary form are stated to be three in number:—
ANCHOVY PEAR. [GRIAS, P. C. S.]

ANCHUSA, a genus of plants belonging to the natural order Boraginaceae, and to the sub-tribe Anchusae of that group. The calyx is 5-fld.; the corolla funnel-shaped, with a straight tube, the throat being closed by prominent oblong nutlets, or scales, or petals, subtended by scales, and the limb of the corolla, when expanded, is 5-fld., and blue or white, or more rarely purple, or pink, or red, or yellow; the personages are numerous, and the fruits are capsules, or follicles, or nutlets. The name is derived from a corruption of anchor, because the same was formerly used to anchor ships. It is an inhabitant of Great Britain, and is a rare plant.

A. officinalis, common Alkanet or Bugloss, has lanceolate, hispid leaves, unilateral crowded spikes, ovate-lanceolate bracts, the segments of the calyx bluntish, hairy on both sides, the scales of the corolla hairy. The flowers are a deep purple.

A. sempervirens, Evergreen Bugloss, has ovate leaves with lower leaves on long stalks, the peduncles axillary, each bearing two dense spikes with an intermediate flower, the segments of the calyx hairy on the outside only, the bracts minute lanceolate, scales of the corolla downy, flowers blue, salver-shaped. This plant is found on waste ground, near ruins, in Great Britain, but is rare.

A. tectoria. Dyers’ Bugloss or Alkanet, has different stems, oblong hispid leaves, bracts longer than the calyx, the segments of the corolla shorter than the stamens. The corolla has a deep blood-coloured tube, with the limb deep blue. The root is woody, descending, and of a dark red colour. This plant is a native of Peloponnesus, the island of Cyprus, and the deserts about Alexandria. It is cultivated in the south of France for the sake of the root, which yields a fine red colour to oils, wax, all unctuous substances, as well as to spirit of wine. Its chief use is in colouring lip salves, ointments, and sometimes pastes, &c. It is also used in dyeing wood and dyeing cotton. It is also used for colouring many of the beverages sold under the name of port wine, likewise the corks used for the bottles in which this fluid is sold. The colouring-matter has been separated, and has been called by the chemists Paeoniae. There is a great abundance in the external parts of the root, the inner being nearly destitute of it. An extract of this root was formerly used in medicine in hemorrhages, but is now seldom employed.

A. aquatica. Narrow-leaved Bugloss, has linear lanceolate hispid leaves, ovate-lanceolate bracts, 5-fld calyx, with blunt teeth. The tube of the corolla is pale purple, the limb deep blue. In gardens it attains a height of 1 foot; but when wild it is not a foot high. It grows in Italy, Germany, and Switzerland, by road sides, amongst rubbish, and on the borders of ploughed fields. It was used by Boerhaave as a medicine; but, like the order to which it belongs, its properties are too insipid to give it a standing-place in the Materia Medica of the present day.

In the cultivation of the species of this genus but little care is required, as they will grow in almost any soil, and are easily increased by seeds. The A. Cyprium, or Personae, which is an annual, is a great plant of a beautiful green. Many of them are pretty annuals for the garden, as A. procumbens, A. Barraillei, &c.

ANCIENT DEMESNE. [MANOR, P. C.; SOCCAR, P. C.]

ANCIENT LIGHTS. [LIGHTS, P. C. S.]

ANCYLOCERAS (D’Orb.). This fossil genus of M. D’Orbigny includes several species of Hamites (Philips), from the Speeton clay and lower greensand.

ANDERSON, JOHN, the founder of the Andersonian Institution of Glasgow, and one of the earliest promoters of...
that popular instruction in science which has so greatly ele-

vated the character of British artisans, was born in the parish of
Renaseth, Dunbartonshire, in 1726. He was grandson of the
Rev. John Anderson, an eminent Scotch Presbyterian minis-
ter, and interoloped as the first minister of the Royal's Horn Church, Glen.
He was left an orphan at an early age, and was educated at Stirling by an aunt; and while there he became an officer in a burgher corps raised in
February, 1746, to defend the town against the forces of the

A right angle is half the opening of a straight line and its continuation; an acute angle is that which is less than a right angle; an obtuse angle is that which lies between one and two right angles. Complementary angles are two which make a right angle; supplemental angles are two which together make two right angles. Two lines which meet and make a pair of angles, one less than two right angles, are called ex-exterior, or re-entering; the other greater than two right angles, are called en-enior, or re-entering. A line, but never a point, is mentioned by Euclid. For salient and re-entering (which are borrowed from fortification) direct and retroflected have sometimes been used.

The angles which two lines make with the same part of a third, on opposite sides of it, are called alternate. Two lines which cross one another make two pairs of vertically opposite angles. The angles made by adjacent sides of a figure are called internal; those made by any sides with adjacent sides produced are external. When the angular point is the center or on the circumference of a circle, the angle is said to be at the center, or at the circumference. Beginners often confound the angle with the angular point.

The angle of contiguity or of contact is an old notion of the opening made by two curves, or a curve and a line, which touch. In modern mathematics, when a curve is supposed to be composed of infinitely small rectilinear elements, the infinitely small acute angle made by one element with the curve, and the production of the next does duty for this old angle of contiguity.

A spherical angle is made by two circles (usually great circles) of a sphere. When the circles meet at the pole of the sphere, the angle is called a horary or hour-angle; and when neither is the meridian, the angle is frequently called horary. The angle of position of a star is that made by the circles drawn to it from the poles of the equator and ecliptic. The angle of elevation is the angle made by a line drawn from the eye to any object, with the horizontal line which is in the same vertical plane as the first line; but when the object is below the horizon, the term is angle of depression. When lines are drawn from two points to a third, those two points, and also the line joining them, are said to subend the angle which is made at the third point. The angle which two objects subend at the eye is their angle of elongation. The angle of the vertical is a name given to the angle which a line drawn to the spectator's zenith makes with his radius of the earth produced. It is taken as nothing when the earth is supposed to be a perfect sphere. Angular terms, such as right ascension, longitude, etc., with which the word angle is not usually coupled, are not considered here. The parasitic angle is simply the Para-

A dihedral angle is the opening made by two planes: it is measured by a rectilinear angle, namely, that made by two lines drawn in the two planes perpendicular to their common intersection. But the rectilinear measure is not the same thing as the dihedral angle, though the two are often confused: we might just as well say that the pressure of the air is the same thing as the number of inches in the barometrical column of mercury. A solid angle is said to exist when three or more straight lines, not in the same plane, meet at a point. It is a complex idea, and the best notion of it as a magnitude is derived from considering it as measured by the area of the spherical tangle which subtends it.

To what we have said under the article Angle, P. C., we may add the following:—If we were to define an angle as the infinite plane space included between two straight lines which meet at, and point, and are produced ad infinitum one way from that point, we should have a sufficient definition, subject only to the question of the propriety of making infinites a part of the elements of geometry. But when the great mathematicians arrived at the conclusion that this definition is the true and proper one: the author of 'Geometry Without Axions,' an acute writer, declares it to be the definition 'whether geo-

ANGE'LICO. [PIERCE, FRA GIOVANNI DA, P. C. S.]

ANGELO BUONARROTI. [BUONARROTTI, P. C. S.]

ANGE. As the explanation of the various ways in which this word is used lies scattered in many parts of the work, the following summary may be found convenient.

An angle is the opening of two lines; rectilinear, of two straight lines; cartesian, of two curves; mixtilinear, of a rectilinear angle, and when a curve enters, its tangent is the straight line which is used in determining the angle.
a triangle are equal to two right angles. Without going so far as to say that this is the definition of an angle, we should recommend it to be admitted and examined as what might be called a distinct proposition of an angle otherwise formed, by means of finite lines, we find much advantage in the knowledge of the following truth—The infinite spaces contained between lines have among themselves all the relations which exist among the angles formed by the lines themselves. The angle best understood is that between as the infinite solid space contained between three planes, that is, between such parts of them as lie between three infinitely produced straight lines which meet at a point.

ANGULO, P. C.

ANGOULEME, DUC DE. [CHARLES X., P. C. S.]

ANGUI/SOICLA, SOFONISBA, greatly distinguished as the 'Cremonese' for her ability in portrait-painting. She was born in Cremona, of a noble family, about 1533, and learnt painting first of Bernardino Campi at Cremona, and afterwards of Bernardino Gatti at Milan. Vasari describes some of her portraits as wonderful, they possessed so much life. Her reputation having reached the ears of Philip II. of Spain, he sent two gentlemen and two ladies of the court in 1569 to invite and to escort her to Madrid, to enter into the service of the Queen of Spain. She painted a portrait of the queen, with which Philip was so much pleased that he sat for her own, and ordered Don Carlos likewise to sit for her. She settled upon her two hundred dollars, and presented her, according to Ceán Bermúdez, with a diamond of the value of fifteen hundred ducats. By these portraits and many others Sofonisba obtained a reputation for portrait-painting which was equalled by none of her contemporaries. Pope Pius VI. requested her to come to Rome to improve his cabinet, and in 1581 at Madrid he procured a portrait of her by the Queen of Spain, in the hand of the Cremonese. Sofonisba sent the portrait with a letter to the pope in the month of September, 1561, and his holiness paid the fair painter the extreme compliment of an autograph answer in the following month, complimenting her highly on her performance. The letter and the pope's answer are both given by Vasari.

Sofonisba was married in Madrid to a Spanish nobleman, Don Francisco de Gonzalez, upon which occasion Philip raised her pension to a thousand ducats, and presented her at her marriage with twelve thousand crowns as a dowry. Her pension was to be drawn from the customs of Palermo, where, after her marriage, she resided with her husband. In a few years however she became a widow, but she found a second husband in the person of Orazio Lomellino, the captain of the Genoese galleys in which she returned to her own country from Palermo. They were married shortly after her return from Spain, in the year 1585. In 1591 Philip raised her pension to fourteen hundred ducats. She painted many pictures at Genoa, by which she added to her reputation, but as she grew old she became blind. She however did not lose her fame, but became the centre of an intellectual society, her house being the resort of the principal artists and men of letters and virtù in Genoa. Vandyck, who frequently visited her, is reported to have said that he had learnt more from the conversation of a blind old woman than from the works of all the great masters of Italy, a report which may not be true.Walpole says that Vandyck painted her portrait at Palermo when she was in her ninety-second year, which would be about 1625, but this statement must be corrected by the circumstance, that she is not known to have returned to Palermo, and she is generally supposed to have died in 1620. If Vandyck painted her portrait when she was in her ninety-second year, it must have been in Genoa, and she probably did not live more than a few years after her marriage. She has never been very certain both of her birth and death. Vandyck was in Genoa in 1619 and in 1623, and perhaps between those dates.

The works of Sofonisba betray none of that fineness of design and modelling which is frequently apparent in the pictures of the French school. They are particularly in the works of Angelica Kauffmann. There are several portraits of Sofonisba by her own hand: there is one at Althorp in Northamptonshire, in which she is represented playing upon a harp; another she painted before 1533: the dates however are very uncertain.

The works of Sofonisba are also to be found in handbooks, such as that of Petteri, and in Ceán Bermúdez, Dictionario Historico, &c.

ANIMAL CHARCOAL. [CHARCOAL, ANIMAL, P. C.; JARROW, P. C.]

ANIMAL FLOWERS. [ACTINIA, P. C.]

ANIMAL MAGNETISM. In the articles Animal Magnetism and Somsambulism, P. C., reference has been made to the fact that several persons, including members of the Society of Mesmerists, have excited much public interest. It will be found from those articles that although this subject had excited much attention on the continent of Europe, in Great Britain it had obtained comparatively a small share of interest. Recently however animal magnetism has had directed considerable attention. By a great amount of attention, it has been investigated by physiologists of eminence, and used as a curative agent by many medical men. In the present article we shall not attempt to summarize all the facts presented by specialists with a view to the rejection or adoption of any theory, but endeavour to give a fair view of its position and claims from the writings of those who have investigated its phenomena.

One of the first publications on the subject was by Mr. Richard Chesewicz, a fellow of the Royal Society, who published a series of papers in the 'London Medical and Physical Journal' for 1829, entitled 'On Mesmerism, improperly denominated Animal Magnetism.' He performed numerous experiments, which were witnessed by medical men, and amongst others by Dr. Elliotson. In 1836 Mr. Colquhoun published a work on animal magnetism, entitled 'Isa Revelata,' which attracted considerable attention to the subject. In 1841 a translation appeared as an appendix to a report of a second French commission appointed to investigate this subject in 1831. This was followed by the arrival of Baron Dupotet in London, who performed many experiments, some of which were witnessed by Dr. Elliotson, who immediately published an account of the further results obtained.

The result of the experiments of Dr. Elliotson, which were published in the 'Lancet,' produced a great sensation, and phenomena which had hitherto been regarded as impossible were constantly produced. Communications were at this time to various medical journals of remarkable cases, and among others were some from Mr. Herbert Mayo, then professor of physiology at King's College, London. In 1840 a work was published by the Rev. Chauncey Hare Townshend, entitled 'Tracts on Mesmerism and the Nervous System.' This work contained many cases and facts with regard to the phenomena of animal magnetism. In 1841 Mr. La Fontaine, a Frenchman, visited England, and commenced giving public lectures on mesmerism and exhibitions of its phenomena. Whilst in Manchester he attracted the attention of Mr. Braid, a surgeon residing there, who, having repeated and modified variously the original experiments of the mesmerists, published a work on the subject in 1844, entitled 'Neuropsychological Researches or the Nervous Sleep.' Since this time various public lecturers have appeared, and have created a general interest on the subject. One of the most recent productions on this subject is a small volume in the 'Animal Phenomena,' which attributes the cure from a long-standing ailment to the influence of animal magnetism.

The phenomena presented by persons under the influence of animal magnetism are various, and are produced by which the phenomena are produced. Mesmer and his followers on the Continent, and most of those who have practised mesmerism in this country, have produced its effects by placing themselves near to the individual to be mesmerised, and making downward passes with their hands by their bodies without touching them, but looking at them at the same time intensely in the face. This is found to affect the individual in a space of time varying from two to three minutes to half an hour. We have however not here to consider the influence, and if an effect is not produced in the course of half an hour, the effort is abandoned. Mr. Braid however, in the course of his inquiries, found that a second individual was not necessary to the successful development of mesmeristic phenomena in those persons. By his person and his causing a partial but not complete corporeal contact directing his attention, by means of the eyesight, to some particular object, as a lancet-case or a cork, all the effects of the passes and intense looking of the operator could be produced. He has caused him to give the same name, Hypnotism, to the state in which persons are thus placed.

The effects of the passes or fixed attention on persons of nervous susceptibility are various. Writers on animal magnetism in many countries are as follows: Classification is by Kluge, a German writer on this subject, a tolerably correct estimate of the effects which have been observed in mesmerised individuals:

First degree—Called waking, presents no very remark-
the phenomena. The intellect and the senses still retain their usual powers and susceptibility.

Second degree:—Half-sleep, or imperfect crisis. Most of the senses still remain in a state of activity, that of vision only being impaired, the eye withdrawing itself from the person, and generally looking downward.

Third degree:—The magnetic or mesmeric sleep. The organs of the senses refuse to perform their respective functions, and the patient is in an unconscious state.

Fourth degree:—The perfect crisis, or simple somnambulism. In this degree it is said to "waken within himself," and his consciousness returns. He is in a state which can neither be called sleeping nor waking, but which appears to be something between the two.

Mesmeric cases have been supposed to be cases of amnestic, or lucid vision. This is called in France, and mostly in this country, Clairvoyance; in Germany, Hellschen. In this state the patient is said to obtain a clear knowledge of his own internal mental and bodily state, is enabled to calculate with accuracy the phenomena of disease which will naturally and inevitably occur, and to determine what are their most appropriate and effectual remedies. He is also said to possess the same faculty of internal inspection with regard to other persons who have been placed in mesmeric or somnambuistic states.

Sixth degree:—Universal lucidity; in German, Allgemeine Klarheit. In this state the lucid vision becomes greatly increased, and extends to objects whether near or at a distance.

Such are the states of the system recognised by mesmerists, and from which dependence is made in each of these six degrees. However, there are many who practise mesmerism who are sceptical with regard to the real existence of the two last degrees, although such cases are recorded by the best authorities on animal magnetism.

One of the most singular statements with regard to mesmerism is its application to phrenology. It is asserted that persons in the sleep-waking state, when that region of the head is touched or pointed at by the mesmeriser which is over the seat of the supposed sense or organ in the brain, will exhibit the mental and states and which are peculiar to the exercise of those organs. Thus when the organ of language is touched, the patient talks; when, it he laughs; when, in allusion, he is kind, and so forth. Such cases the first stated by Dr. Elliotson, Mr. Brain, Mr. James Simpson, and others.

The mesmeric state has been applied mostly to the cure of disease, for which purpose it was used by Mesmer when it first attracted public attention. It has also been used for the purpose of producing sleep during surgical operations, as well as a means of diversion for the purpose of ascertaining past and future events, as related in the case of Miss Martineau's affection. The class of diseases which have been cured by its means include the different known to medical men as functional nervous diseases. Various nervous diseases, such as paralysis, epilepsv, &c., come on from changes in the structure of the nervous organs, but these are not susceptible of benefit from the influence of the mesmeric state, since, as already stated, no structural lesion can be supposed to exist, and which often yield to sudden changes of the mind from various causes of excitement, and which frequently cease without obvious cause, that has hitherto yielded to this remedy. To this class of diseases belong those of Miss Martineau, to which we have before alluded, who has been relieved of her nervous symptoms by mesmerism, whilst an organic disease still exists. (Report of the Case of Miss H. M., by Mr. Greenhow.) In the article by Dr. Souter, in the second edition of the Encyclopaedia Britannica, it is said: "No operation was performed during sleep artificially induced, and many cases of a similar kind have recently been recorded.

Many theories have been proposed in order to embrace the effects of animal magnetism. Mesmer and his immediate followers attributed to them the action of a subtle fluid in the bodies of animals, which enabled them to exercise an influence on each other at a distance, just as a magnet affects iron; hence he called it animal magnetism. This hypothesis of a universal animal magnetism has received great support from the discovery of the connection of the cerebral centres and of the circulatory and respiratory and muscular systems, induced by a fixed state, absolute repose of body, fixed attention, and suppressed sensation concomitant with that fixity of attention. He further adds, that in all cases he believes that the patient depended on the physical and psychical condition of the animal, arising from the causes referred to, and not at all on the volition or passion of the operator throwing out a magnetic fluid or exciting into activity some mystical universal fluid or magnetic will.

While there can be little doubt with regard to many of the facts recorded on this subject, they have been so remarkably misrepresented through the influence of those who have observed and narrated them, that men of science, disgusted with the imposture of some and the credulity of others, generally shunned its investigation and turned a deaf ear to what they consider the pretensions of its professors. There have been however recently recorded instances in which much has been attributed to suggested observers, and which have led to the conclusion that in these particular cases either imposition was practised or a false conclusion had been drawn from the facts. In the case of two girls put to the test by Mr. Wakley, editor of the Lancet, and recorded in that periodical for September 1, 1838, there was strong reason to believe that many of the phenomena attributed to animal magnetism were assumed at the will of the patient. A more recent instance is recorded by Dr. John Forbes, in the Medical Journal, April 3, 1844, in which he states the powers of Clairvoyance of a French youth named Alexis. Some of these experiments, which were conducted before many observers, the youth entirely failed to give evidence of any extraordinary mental powers during the mesmeric state. Dr. Forbes remarks: "I have repeated a large number of the experiments, 'It is necessary to repeat here what I have stated in the notes, that mesmerism may be true, while its professors are false; that negative results must of course give way to positive ones; and that I for one am still unconvinced that Clairvoyance has not existed, and does not exist, mere because Alexis on these occasions failed to show it. Independent of the motive of gain which actuates some, it is admitted by mesmerists that the class of persons who are most susceptible of the influence of mesmerism are those who have a disposition to deceive, that is, are exceedingly difficult to say when, or upon what occasion, their statements are to be relied on.'"

In this article we have avoided expressing an opinion, and have given only an outline of the present position of animal magnetism in this country.

(For further inquiry refer to the works quoted, and to Elliotson, Human Physiology, 6th edition; Lang, Mesmerism, its History, Phenomena, and Practice; the Atheneum for December, 1844; and the Zoist, a monthly journal which advocates animal magnetism.)

ANIMAL PHYSIOLOGY. [PHYSIOLOGY, P. C.] ANIMAL STRENGTH. Efforts were made to express the amount of human and animal labour in a uniform system of measurement, but the production of a unit capable of universal application, as well as free from the disadvantages of the scale proposed by D'Arçon, which was published in 1680, in the 'Memórias da Academia das Sciences' for 1699, there is a unit of animal strength, and, by M. de l'Hire, for 1703, which he calls the animal unit. It consists of the sum of all the forces necessary for the execution of a given task, that is, the work performed by a horse is equal to 512 of them. In this way, the strength of the states of force, that is to say, the power of action, may be expressed in terms of the animal unit, and that may be applied to measure the relative forces of different animals. This is what is meant by the term 'animal unit,' and is defined as the amount of work that can be done by a horse in a given time, and is the basis of all experiments in this field. The strength of a horse, for example, is said to be 100 animal units, and that of a dog is said to be 10 animal units. It is a useful and practical unit for comparing the strength of different animals, and is widely used in the study of animal physiology.
to a distance equal to one kilometre (≈9280-9 feet, or 2-6124 miles English); and his expression for strength is, therefore, the number of the kilometres by the number of distances to which the burthen is conveyed during one working day. Other mathematicians take, for the dynamical unit, the weight of a cubic metre of water conveyed one unit: neither of these units is, however, convenient for persons among whom those weights and measures are used. In the following, in the results of the remarks experiments have been made to correspond to a unit expressed by one pound (avoirdupois) conveyed one mile; every number expressing strength is, therefore, the product of the number of pounds by the number of miles or which it is conveyed in a day.

With respect to men, Coulomb found that when a man travels unloaded on level ground, he can walk 31 miles daily. Now, assuming the weight of a man to be 100 pounds, we have 160 x 31, or 4960, for the number of burdens, which should be the quantity of action; which is consequently equivalent to that of a machine capable of carrying 4960 lbs. to a distance of one mile, or one pound to a distance of 4960 miles in one day.

He found also, from a mean of the work done by the porters of Paris, that with a burthen equal to 128 lbs. a man can walk 9-72 miles in a day; from which it follows (the weight of a man being 160 lbs.) that the quantity of action is (160 ÷ 128) x 9-72, or 11-5 lbs. to the mile. This number is not included, the quantity of action is 128 x 9-72, or 1244; and this is to be considered as the useful effect. Subtracting 2790 from 4960, we have 2161 for the measure of the action lost in consequence of the burthen; but the useful effect, which in the first case was 1155 lbs., in this second expression is 2044.

Now, if $f$ represent the burthen which would prevent a man, or animal, from moving, and $v$ the velocity with which he would move if unloaded; also, if $F$ be the burthen due to a velocity expressed by $v'$; we should have, according to Euler,

$$f = f' + (v' - v)v$$

or

$$F = F' + (v' - v)v$$

making therefore $f' = 128$, $v = 9-72$, as in the example above, we have 272 nearly for the value of $F'$; or the greatest burthen, in pounds, which a man supposed to be of average strength can carry, and under which he could not move.

From the equation above we have

$$v' = \frac{F}{F'}$$

therefore, in order to find the maximum value of $v'$, we may make the differential of the second member equal to zero, $f$ being the variable), which will give $f' = F'$. So, or 121 lbs. This is the weight which should be placed on a man's shoulders, when it is required to produce from his labour the greatest possible effect. Making $f' = 124$, and $v = 9-72$, and $v' = 31$, in the above equation, we obtain $F' = 272$, or $v' = 10$; nearly, for the distance to which the burthen $F'$ could be carried in one day; and $f'v'$, the quantity of action, is 3450 lbs.

Coulomb further determined that when a man ascends a convenient flight of steps unloaded, the vertical heights of all the ascents during one day being added together, were equal to 1.92 miles; the quantity of action may therefore be expressed by 160 x 1.92, or 307 lbs. and the action was equivalent to that of a machine which could raise 990 lbs. to the height of one mile vertically, or one pound to the height of 991 miles during a day. When loaded with 150 lbs., the vertical height ascended was 0-494 miles: the whole quantity of action is, therefore, given by 160 x 0.494, or 79, while the useful effect is 150 x 0.494, or 74; that is, 74 pounds raised one mile vertically.

It is remarkable that, from the result of Coulomb's experiments on the power of man and beast, the gross weight which a man can carry without moving, and the weight which he should bear to render his useful effect a maximum, are nearly the same in this case as they were found to be from experiments made with burthens carried on level ground.

Coulomb has also made experiments to determine the quantity of action in the case which most generally occurs when heavy goods are carried in towns, viz. that in which a porter, having delivered his burthen, returns unloaded for another; and he has, in order to produce the most useful effect in this case, the greatest burthen which a man should carry on level ground is 156 lbs.; and with this he should walk 7 miles. The quantity of useful action is therefore 135 x 7, or 945.

It is said that a London porter can carry 200 lbs. on his shoulders at the rate of three miles per hour; but this action can only be continued during a short time.

The following statements of the strength of men are taken from Hachette's 'Tract des Machines,' and from other sources; the numerical values being reduced so as to express the number of pounds carried by a man one mile per day of eight hours:

- **Drawing a vessel on a canal:** 7584.59 lbs.
- **Conveying a load (110 lbs.) in a wheel-barrow:** 291 lbs.
- **Drawing a heavy wagon on four wheels over rather unequal ground:** 857 lbs.
- **Pulling horizontally, the weight being raised by a rope passing over a pulley:** 378 lbs.
- **Rowing in a boat:** 291 lbs.
- **Travelling, as at a captain:** 368 lbs.
- **Turning a winch and axle:** 745 lbs.
- **Digging with a spade:** 85-3 lbs.
- **A soldier marching (12-48 miles) with his arms, &c. (50 lbs.) daily:** 745 lbs.

With respect to horses, the most useful way of employing his strength is to make him draw loads in a cart or wagon; but, even for such work, the estimates which have been made of the quantity of action performed daily are various.

M. Hachette expresses the whole quantity of the action of a horse of medium size as equivalent to 309 lbs. drawn nearly 25 miles in a day; and consequently such action should be represented by 309 x 25, or 7725. But, according to Tredgold, a horse can only draw 125 lbs. at the rate of 24 miles per hour; which, for one day, would give 125 x 24 x 8, or 2500 lbs.

The useful action of a horse with a load, as in some mills, is considered as equivalent to 800 lbs.

A horse carrying a soldier with arms, &c. (≈300 lbs.) can go 25 miles in a day, which gives 15000 lbs.

An Arab, by prolonged carryings, with his rider (160 lbs.), can go between 7 and 8 miles per hour during 9 or 10 hours; which gives 160 x 7-94, or 11500 lbs.

An Asiatic camel will carry burdens weighing from 350 to 450 lbs. (suppose 600) at the rate of 4-6 miles per hour. This, for a day of 8 hours, gives 600 x 24 x 8, or 12000 lbs.

The velocity of a horse in walking is estimated at 34 feet per second, or 39 miles per hour. In trotting, 12 feet per second, or 14 miles per hour; and in galloping, 18 feet per second, or 43 miles per hour.

For drawing on a road, the traces of a horse should be perpendicular to the collar on his breast and shoulders, so that when he leans forward, in pulling, the traces may be nearly parallel to the ground. The rate of the wheels should be determined accordingly. When, in drawing a two-wheeled carriage, a horse has to overcome an obstacle on the ground, he lifts up his fore-feet, and allows his weight to act upon his hinder feet as fulcra, till the wheels have passed over the impediment. It follows, that a certain portion of the loading of a cart should be thrown on the back of the horse, in order to increase the power which the animal employs in overcoming an obstacle; and, in ordinary circumstances, it renders a considerable inclination forward unnecessary.

When a horse is employed to turn a mill, the circle which he describes should be the greatest possible, 25 or 30 feet in diameter, both to diminish the centrifugal force, and the necessity which the animal is under of reeling from a vertical position.

ANIMAL TISSUES. [Tissues, P. C. S.]

ANKBAR. [Asteinia, P. C. S.]

ANTOLO. [Antotto, P. C.]

ANIMIES AND ANICEANCES. We add some of the most recent information on the subject to what we have said in REVERSINES, P. C.

The completion of Mr. Jones's work on Annuities, in the Library of Useful Knowledge, has given computers an immense mass of tables, involving all that can be necessary as far as two lives are concerned. Barrett's method, in particular, is applied to two lives, for various rates of interest.

The 'Life Assurance and Annuity Tables,' by Edward Snow, Edinburgh, 1841, fourth edition, will, through several years, the Carolina Table, and 3 per cent, in every point of view a remarkable work. It contains the present values and pre-
The subject has been well given, and reference to authorities facilitated, by Mr. Edwin J. Farren, in an 'Historical Essay on the Rise and Early Progress of the Doctrine of Life Contingencies in England,' London, 1844.

The actuarial table (as it ought to be called) contains the experience of the Amicable and Equitable societies, which had been previously printed, and which afforded conjointly a large majority of the policies employed. We give a summary of these, namely, the duration of life among 100 persons at quinquennial periods of age.

In the following table, columns C. and E. contain the Carlisle and Equitable tables [*Mortality, P.C.]: A. is the Amicable table above noticed. All on the right of the double line comes from the actuarial tables; in which the data are divided, as far as was practicable, into policies effected in town (London), in the country (other parts of Britain), and in Ireland. The first table, M. T. C. I., is that of males only, town, country, and Irish; F. T. C. I. the same for females; the remaining tables contain both male and female lives, T. town, C. country, I. Irish, C. T. combined town (which is explained to be the total experience of the Equitable and Amicable combined with the town experience from other quarters, the reason of which we do not see); G. I. the result of all the materials, including the Irish; G. the same not including the Irish.

Thus 100 individuals at 35 years of age have among them 3100 years of life according to the Carlisle table, and 3055 according to the general result of the actuaries.

These tables present that general agreement with the Carlisle table which the Equitable experience first showed. It appears that the town-insured have a very little more life than the country, not more perhaps than can be very well explained by the greater difficulty of making good selection through an agent. The result of the Irish lives is startling; it is not credible that the middle age of an Irish life at forty years old should have five years less life in him than an Englishman of the same age; the necessary inference is, that the offices have done Irish business without sufficient precautions.

The vitality of the Carlisle table seems a little too high; but, though if the difference were serious, the offices should of course adopt their own experience, yet it does not follow that such experience better represents the state of life among the insured class. Probably those who sell or surrender their policies, as not being best test of who are the people of the best health, for it is not known that ill health is close at hand prefer to remain.

It appears that male insured life is slightly better than female, on the whole; which is contrary to all else that is known about the relative values of the two. Perhaps female lives are, more frequently than male ones, insured from fear of permanent symptoms or hereditary tendencies. A man insures his life either for his family or to obtain an advance of money, and apprehensive of speedy death nothing to do with the disposition to insure in either case; a woman has, generally, not so many reasons, independently of forebodings, to insure. There is then probably a large proportion among women (of the friends who insure their lives) of the undesirable cases in which parties insuring have reason to know more about the state of the life insured than their medical attendants, as to causes of death which are not likely to act soon. We do not much like being forced upon an explanation which presumes something like consentment in so large a number of respectable persons; but some reason must be for

It thus appears that the effect of selection is most decided
m young lives, and that if apparently healthy lives were substituted, in a mass of persons in all conditions of health, in the place of those who would be refused by an insurance office, the policy would add more than two years of life to each case, at any age from 35 upwards.

ANNULARIA (Sterenberg), a genus of fossil plants with leaves in whorls, from the coal formations of Europe and America. ANOMALINA (D'Orb.), one of the many genera of FORAMINIFERA [Fossil, P.C.S.] which occur in tertiary strata.

ANTHOCYTIES (Bromghiart), a fossil genus of Ferra, found in the basalt sandstone of Salzburg.

ANSWER. [Pladino, P. C.]

ANTHEMIUS NOBILIS (COMMON OR ROMAN CHAMOMILE)—Medical Properties of. This is an indigenous plant, frequent on our commons; but the flowers used in medicine are generally obtained from cultivated plants. Of these there are two kinds, the single or semi-double, and the perfectly double. The doubling of the flowers is attended with a lessening of their virtues, as the single are more aromatic, and contain more volatile oil, which resides in the yellow tubular florets of the disk. Their excellence may be determined by the beautiful whiteness of the radiant florets, the yellowness of those of the disk, and the strength of the aromatic smell.

Those which are brown, mousy, and faintly smelling, should be rejected. They contain a volatile oil of a beautiful blue colour, camphor? a gum resinous principle, and a small quantity of tannin.

The difference of both of taste and smell, the diversity of the oil, and the absence of the camphor-like principle, allow the impurity of substituting for the Anthemis the flowers of the Matricaria Chamomilla (or Feverfew). In this genus the receptacle is naked. The Anthemis it is palaceous, besides, the flowers are similar, and of an unpleasant smell. The flowers should be gathered before they fully expand. The forms of exhibition are, powder, infusion, extract, and oil.

Chamomile is an excellent bitter and tonic agent. Given in powder, or pill, or extract, with addition of a few drops of the oil, it is of great service in dyspepsia, atonic gout, and in intermittent fevers. The infusion may be made the vehicle for alkalies or acids.

The infusion when tepid is emetic, and may be given beneficially in diabetes, and at the commencement of catarrh, (particularly influenza,) and hooping-cough.

The decoction is an objectionable form, as it dissipates the oil. Even the infusion should be made with cold water. A most grateful aperient for weak dyspeptic patients is made by steeping serveridae leaves, chamomile flowers, and a very few caradions for ten hours in cold water, straining, and adding to the infusion any saline medicine required. The extract possesses medicinal virtues, but in preparing it the volatile oil is dissipated, which deprives it of its therapeutic value. This may be restored to it by adding a few drops of the volatile oil. Extract of chamomile, with sulphate of quinine, and the volatile oil, furnishes a combination of immense power in improving the appetite and aiding the digestion in convalescences from acute diseases, or after an attack of gout.

Infusion of chamomile, either warm or cold, furnishes an excellent application to weak eyes, or after exposure to the wind in travelling, especially by railroads. This used early will often ward off inflammation.

ANTHEMIS (OR ANACCYLUS) PYRETHRUM—Medical Properties of. Pellitory of Spain grows in the south of Europe, north of Africa, and in Syria, but the root of a species called Pellitory of a deeper red, native of Germany, is also met with. The first is called the Roman or true Pellitory, the latter the German: this is necessary to be known, as the chemical analysis varies considerably. Gauthier seems to have analysed the Roman, and found it to contain—

| An acrid fixed oil (resin) | 5 |
| Volatile oil (a trace) | 14 |
| Gum | 11 |
| Inulin | 33 |
| Muriate of lime (a trace) | 35 |
| Woody matter | 5 |
| Loss | 100 |

It is devoid of smell, and though it does not at first excite any sensation in the mouth, it is followed by a pungent taste, and flow of saliva.

Its use is confined to local affections of the mouth, where subcutaneous or paralytic. In rigidity of the muscles of the jaw, or rheumatic pains, from exposure to currents of air, showing this is often of great service. An infusion may be held in the mouth, also in toothache from cold. A mixture may be made of it, which would be a useful agent in paralysis of the stomach, added to the infusion.

ANTHEMIUS (Anthemius), a distinguished mathematician and architect of the sixth century. He is sometimes called Anthemius Traianus, from his birthplace Traul in Lydia. Alexander Trallianus the celebrated physician was his brother of Anthemius, and he had three other brothers who distinguished themselves, according to Agathias. Anthemius was the most distinguished of the architects employed by Justinian at Constantinople: he began to rebuild the church of St. Sophia, after it was destroyed by the populace in 581, and it was completed after his designs by Isidora of Miletus, after the death of Anthemius, which seems to have taken place in the year 594. The church was not finished until 537, but the dome fell in two years afterwards, through the shock of an earthquake; it was however again rebuilt by lardus, and the dome then raised was the first that was ever built upon arches and piers, and still remains; it is 105 feet in diameter, and composed of stone.

The mechanical genius of Anthemius is praised by Agathias, and he must have been distinguished also as a mathematician, as Eutocius has addressed to him his commentaries on the Conics of Apollonius Pergaeus. Halley published an edition of these commentaries, Greek translations, Greek commentaries of Eutocius, at Oxford in 1710. M. Dupuy published in 1777, at Paris, a fragment of a work by Anthemius on mechanical paradoxe: Pupil Plagabatou Meyagwurmous, with a French translation, and notes, entitled 'Fragment d'un Ob- vage Grec d'Anthemius sur des Paradoxes de Mécanique.' (Procopius, De Aedificiis Justiniani, l. i. De Templo Sanctae Sophiae; Agathias, Hist. l. v.)

ANTHIANUS, FURIUS, a Roman, from whom we get on the subject of Pontius Pilatus, much more correct accounts of the Digest. [JUSTINIAN'S LEGISLATION, P. C.] The age in which Anthianus lived is unknown.

ANTHOLITHES (Bromghiart). Some fossil plants that designated occur in the coal formations of Shropshire and Northumberland.

ANTHOPHYLLUM (Schweigger), a fossil genus of MADDREPHYLLICA, P. C.

ANTHOSPERMEE (from a, flower, and erize, seed). A genus of plants belonging Antho sperma (the rib-ber-tree), belonging to the natural order Cinchonaceae. It consists of the genera Cordosma, Phyllis, Galopina, Ambria, and Antho sperma. They possess dioecious or hermaphro- dite flowers; a rotor corolla; styles separating to the base, exuding an agreeable gum and yellowish resin; the fruit consists of 2 indehiscent 1-seeded mersiscarpus, or nuts; the flower of the seed is fleshy. The species are small herbs or shrubs, with opposite or verticillate leaves, and small 1- torched stipules, which are adnate to both sides of the peo- ticles.

None of the species are used in the arts or medicine; the tribe is however interesting as forming a link between the opposite-leaved Cinchonaceae and the verticillate Battiglias. Although most of the Anthospermaceae have opposite leaves, yet several species of Anthospermum itself, as A. Bergainianum and A. Anthophicum, have their leaves subverticillate. In Phyllis the leaves occur in whorls of three or four. This genus but a few years since became known to botany by the common name of the Ob- hare's-car. It may be cultivated, with other species of the tribe, in a mixture of loam, peat, and sand.

ANTHROCOTIUM (Cuvier), a fossil genus of Pachyderm mammals, of which many species occur in the deposits, especially in the gypseous and lignite strata of Piac and Tuscany.

ANTICLINAL, a term in geology which expresses the fact that, from a given line, the strata dip in opposite direc- tions.

ANTIDICOMARIANITES (from the two Greek words antidikos, adversary, and maris, Mary). A sect of so-called heretics, whose peculiar belief was that Mary the mother of our Lord did not continue a virgin after her marriage. The Roman Catholic Church asserts that she did this to the end of her life, but bore other children to her husband Joseph. This doctrine seems to be countenanced, not only by probably
and common sense, but by the statement of St. Matthew, that Joseph knew not his wife till she had brought forth her first-born son, and by the mention in various passages of the Gospels of the brothers and sisters of Jesus. (But see what is said as to the meaning of the expression in the New Testament.) The founders or first preachers of Antidotearianism were Hel- vius and Jovinian, two Roman theologians of the latter part of the fourth century. The principal objections to them were raised by various other heretics. The original accounts of Helvidius and Jovinian, and of their opinions, are to be found in the writings of Augustine, Jerome, and Euphronius, who were their contemporaries. There is a small island opposite the north-western part of the island of Milo, the ancient Melos, in the Archipelago; it is about five miles from the harbour of Milo, and opposite to it, a little to the north-west, so that the main sea cannot be seen from it. The hills two or three miles the island appears to be a round mountain rising out of the sea, but, on coming nearer, a peak is observed in the centre with steep acclivities forming several small capes, between which are little bays.

\textbf{ANTIPATER, LUCIUS CAELIUS. [CaECilius, P. C.]}

\textbf{ANTIPHIUS, (\textit{Antiphius}) a celebrated Greek painter, who lived in Egypt in the time of the Ptolemies, was the pupil of some distinguished artist n. c. He is praised by Quintilian for the facility with which he painted, and Pliny mentions several of his works, in various styles. He painted—Hesione; Alexander, Philip, and Minerva; Bacchus; Alexander as a boy; Venus and Mars attending to each other; two horses frightened by the sea-monster sent against him by Neptune, a comprehensive and difficult subject: these were all in Rome in Pliny's time. Pliny also mentions the following—Polemy hunting; a boy blowing a fire with reflection upon his face and the surrounding objects; a room full of women spinning and weaving; and a Satyr looking out—was standing with his hand over his eyes, and a panther’s skin hanging from his shoulder: the last was a very celebrated picture. The following description of Antiphius is taken from the work of another writer, who notices the above pictures. Antiphius was the inventor of a kind of caricatures called \textit{Griffii}. They were a species of grotesque monsters, part man and part animal or bird, of which the Greeks and Romans appear to have been fond. Antiphius therefore added variety of style to facility of execution. He was a native of Egypt, and his time is fixed by a circumstance connected with him mentioned by Lucian in his treatise against Calumny. Some writers have inferred that he lived in the times of the Ptolemies. But it is probable that we have here a confusion in the author, who says that Quintilian mentions him, and because Pliny states that he painted those pictures; but their pictures are not noticed as portraits, but simply as pictures, and which may have been painted at any subsequent period. Quintilian speaks of Antiphius as one of the two greatest ancient artists; he mentions Alexander and his successors, but he speaks vaguely; Polemy Philopator however, though the fourth of the Ptolemies, may be strictly spoken of as one of the successors of Alexander. The circumstance related by Lucian shows a black side to the character of Antiphius. Being jealous of a painter of the name of Apelles, a citizen of Ephesus, who was then on a visit at the court of Ptolemy, Antiphius accused him of being a participator in the conspiracy of Theodotus at Tyre. Theodotus was Euseus, the governor of Cae-Sara, in which his conspiracy took place, according to Polybius, in 218 n. c. Polemy at first believed the accusation, and Apelles was apparently imprisoned, but upon his innocence being established, Polemy not only presented him with 10 talents, and condemned Antiphius to be his slave, a part of the indemnification probably which the painter would not be disposed to put in force. Apelles was however not satisfied with the handsomely conduct of Polemy, and when he returned to Ephesus he sent a letter to Polycrates, the son of Eutytus, in which he charged the Egyptian king with treating him in a very ridiculous manner—and he was preceded by Envy and followed by Deceit and Artifice; in the background were Repentance and Truth. The allegory is evidently bad; the subject is inapplicable; but it presupposes a thorough knowledge of iconology, or allegorical personation, in the spectator. 

\textbf{ANTONELLO DA MESSINA, a celebrated Italian painter, distinguished as the first Italian who painted in oils, as it is termed. Neither his name nor any date connected with events of his life are exactly known. He was born at Messina about the year 1414, and was instructed in painting by his father Salvator d'Antonio; he then studied in Rome, and returned to Messina an accomplished for his time, and acquired considerable reputation by some works which he executed at Messina and at Palermo. In about the year 1442 he had occasion to visit Naples, where, in the possession of the king, Alfonso I., he saw a picture executed in a manner and with materials quite new to him: this was a picture of the Amniation by Giov- anrino da Bruggia, which immediately struck him as belonging to the new method to Domenico Veneziano, who was murdered
in Florence in 1464, by Andrea del Castagno, after he had obtained the secret of the new method from him. From Venice Antonello repaired to Milan, where he probably dwelt some years, and about the year 1468 he returned to his native city. In Venice he lived upwards of 20 years in the enjoyment of the reputation of one of the most distinguished painters of his age. He died aged 49, but from various circumstances this is evidently an error: he probably mistook 49 for 49 in his authority. Domenico was said to have been assassinated when Antonello was 49, which was, as near as can be ascertained, in 1446; if Antonello was as aged 79, when he died his birth and death, 1414 and 1495, and the last date corresponds with the year when the repairs in the palace of the Signory of Venice were completed.

Antonello appears to have made secret of his new method of painting after his second visit to Venice, for in 1578 Bartolomeo Vivarini painted a picture in the new manner for the church of the SS. Giovanni e Paolo, and Antonello himself marked his pictures 50 pixit. There is at least one so marked in the possession of a gentleman at Utrecht: it represents Christ between the two thieves, and 'Antonellus Messenscus me 50 pixit, 1475,' is inscribed upon it; it is a small picture painted upon a panel of wild chestnut. The 56 evidently signified oil, or in oil; a word which is used later in the account of the method of painting by which, simply in oil was very old, and that of Van Eyck was not merely painting in oil; it was, according to Vasari, painting in vernis. Vasari says that Van Eyck, by boiling linseed, poppy, and nut oils, with wax, obtained that medium which every other painter in the world had long desired. From this statement it is evident that painting in oil is strictly a misnomer, and it was adopted only as sufficiently descriptive in contradistinction to the then prevailing method of water-colour or tempera paint.

Antonello's works were distinguished for tone, for brilliancy of colour, and for the excellence of his impasto, but those which remain are much darkened. In design they are similar to those of the Berrini. Antonello's life was long, and he was industrious; the extreme sensibleness therefore of his works cannot be otherwise accounted for than by supposing them to be attributed to other masters, or vaguely designated as of the school of Van Eyck, a very frequent designation in the continental galleries. There is only one picture by him in Venice—the Virgin reading in the Academy. Bocchi (1733) mentions only one—A dead Christ supported by angels, in the chamber of the Council of Ten, which appears to be now in the gallery of Vienna, but how it was removed from Venice is not stated. At Messina, in 1792, there were still twelve small pictures by Antonello, around an old altar-piece. Messina, in the museum of St. Gregory. At Munich, in the gallery of the Duke of Leuchtenberg, there is a portrait by him of Caterina Cornaro, queen of Cyprus.

(Vasari, Vite de' Pittori, &c., and Sehorns Notes to his German translation; Poccini, Memorie Istorico-Critiche di Antonello degli Antoni, Pizzaro Massinesse, Florence, 1869; De Bast, Messager des Sciences et des Arts, Gand, 1824; Boisserée, Kunstblatt, 1826; Passavant, Kunstreise durch England und Belgien; Lauti, Storia Pitteria, &c., vol. ii.)

APHELION. (Theor.) A spherical, or more nearly so, surface, the centre of which is the principal focus of a paraboloid of revolution. The equation of the section of the paraboloid by a plane through the axis is

\[ y^2 = 4ax \]

where \( a \) is the parameter of the paraboloid. The equation of the section by a plane parallel to the axis is

\[ x = 2a. \]

The abscissa of the point of intersection of the plane with the axis is called the axis of the paraboloid, the ordinate is the parameter, and the line from the vertex to the point of intersection is the axis of the paraboloid. The equation of the section by a plane perpendicular to the axis is

\[ x = 2a. \]

The abscissa of the point of intersection of the plane with the axis is called the axis of the paraboloid, the ordinate is the parameter, and the line from the vertex to the point of intersection is the axis of the paraboloid. The equation of the section by a plane parallel to the axis is

\[ y^2 = 4ax \]

where \( a \) is the parameter of the paraboloid. The equation of the section by a plane perpendicular to the axis is

\[ x = 2a. \]

APHELIUM. (Arctis). [Apsidiala, P. C. S.] APICORINITES (Miller), a fossil genus of Crinoides, found in the oolitic formations and in the chalk.

PLANE LENS. (From the Greek, plana, without, and \( \varepsilon \), deviation or aberration) is one which should be capable of so refracting all the rays which, diverging from or converging to any one point in the axis, are incident upon it, that after being transmitted through it they may converge to or diverge from any other point in the same manner.

The spherical forms which are given to the surfaces of lenses, and the dispersions of the different coloured rays in each pencil of common light, are the causes that the rays of any one colour when incident on a lens in the circumstances of a given case, are scattered from their just true paths, and, therefore, rays of different colours in any one pencil however slender, do not converge in one point; and the diffusion of the various points of convergence about the geometrical focus of the lens is the aberration which it is proposed to correct as far as possible by giving appropriate forms to the surfaces, or by combining together two or more lenses.

Writers on optics show that a curve-line by whose revolution about an axis there shall be described a surface which, being that of a refracting medium, will cause all rays incident upon it, when they diverge from or converge to one point, to be refracted so as to converge to or diverge from one point is, in its most general form, of the fourth order: but when the radiant point is at the focus of the refracting surface, as when it is at a celestial body, the form of the refracting medium is such that the rays, when within the medium, converge accurately to the focus most remote from the place of incidence. If the refracting medium were less dense than that in which the rays are incident, the surface would be that of a hyperboloid. The semi-circle was the form of the sphere, the sphere was that of the hyperboloid, and the sphere of the spherical aberration, or the eccentricity, as the sine of the angle of incidence is to the sine of the angle of refraction: in the former case the refraction is from the surrounding medium into the sphere: in the latter case the refraction is from the sphere into the surrounding medium.

It follows that there is a meniscus less dense than the surrounding medium which has the anterior surface spheroidal, and its posterior surface that of a sphere whose centre is at the further focus of the spheroid; since the rays will then suffer no deviation in passing through the posterior surface, it will be aplastic. Also if the anterior surface of a medium be plane, so that the parallel rays incident perpendicularly on it may suffer no refraction in entering, and the other surface be part of an hyperboloid, the medium between them is that in which the rays, after passing through the plane lens thus formed will be aplastic; the refracted rays converging to the opposite focus of the hyperbola.

The form of the expression for aberration, when parallel rays are incident upon an hyperboloid, being of the form

\[ y^2 = 4ax \]

it is such that the aberration cannot be made to vanish with any real values of the radii of those surfaces unless the index of refraction in the medium were equal to or less than 0.25. But there is in nature no medium which has such a refractive index; therefore, in falling in making spherical lenses strictly aplastic, and it has been found impossible, hitherto, to form them with surfaces produced by the revolutions of conic sections, mathematicians have investigated expressions for the form of surfaces which, for all angles of incidence, would make the aberration of the focus to be a minimum; see the article 'Light' in the Encyclopædia Metropolitana (art. 306), where the ratio between the radii of the surfaces, in this state, is given. From that ratio it is shown that, when the index of refraction is 1.5, the lens should be of the double convex form, having the radius of the posterior surface six times as long as that of the anterior surface, or that which is nearest to the radiant point.

For an investigation of the radii of the surfaces of lenses we may turn to the General Theory of Errors, as combined together for the purpose of diminishing as much as the same time the chromatic and spherical aberrations, see TELESCOPE, P. C.; and, in the treatise on light above quoted (art. 313, 468). Sir John Herschel has given four equations involving the refractive indices of the materials of the lens, and the principal focal distances, from which the four radii may be obtained consistently with the condition that the aberration shall be zero. From the equations, and with different refractive indices, there is computed a table of the radii of the lenses for the compound object-glass of a telescope as nearly aplanat...
the hypotkecium, and the other the perithecium.

In lichens the reproductive matter appears on the surface of its frond or thallus in two forms. First, in the form of little coloured cups or lines with a hard disk surrounded by a rim, and containing tubes filled with sporules; and secondly, in the form of little heaps of pulverulent matter, which are scattered over the surface of the thallus of the fungus. These organs form the principal means of distinguishing the various forms of lichens, and consequently it has been found convenient to indicate minor points in their structure by other names. Thus the apothecium, which in English is called a shield, consists of the sporocarps containing the sporules, enveloped by a shield with an elevated rim; Pelea, a flat shield; Tuberculatum, a convex shield; Trica or Gyroma, a furrowed shield; Lirio, a linear shield; Globulus, a round deciduous shield; Polysiphon, an orbicular, smooth, cylindrical shield. The parts of the apothecium or shield have also obtained distinct names: such as perithecium is the inside of the shield, in which the sporules are immersed; hypothecium is the substance that surrounds or overlies the perithecium; nucleus is the disk of the shield, which contains the sporocarps; its cases; and ascus are the tubes in which the sporules are contained.

Apothecia is also the same name given to the cases in which the organs of reproduction of many of the Algae are contained. The reproductive granules contained in the apothecia of both Lichens and Algae are called by some writers gonothyrs.

APPARITOR, an officer employed as messenger and in other duties in ecclesiastical courts. Apparitors, says Burn, are 'so called from that principal branch in their office, which consists in summoning persons to appear.' The canons direct that letters citatory are not to be sent by those who have obtained them, nor by their messenger, but the judge shall send them by his own faithful messenger. It is the duty of the apparitor to call defendants into court, and to execute such process as may be given to him; but this duty is not to be performed by deputies. In 21 Hen. VIII. cl. 5, as well as in the canons, apparitors are also called summoners, or sumners. The above act restrains the number of summoners, but does not restrain the names assigned to their cases; and such are the tubes in which the sporules are contained.

The apparitors of the ecclesiastical courts are paid by fees, which in most cases amounts to a very small sum annually. The earnings of the apperators of the Prerogativa Court of Canterbury are however considerable, and in 1648 amounted to 300.

Apparitor is a word not used, and was used as a general term to signify any person who was in attendance on public functions. It was sometimes given to Piombino on the 30th day of September, the day on which the orders. The term accordingly includes a great variety of officers in the Roman system. Under the latter Empire most of the magistrates and functionaries had their apparitors, whose duties and privileges are enumerated in the Justinian Code, 12. cit. 69, &c.

APPAREANCE. [Pl. 12, p. 320.]

APPEAL TO THE SESSIONS. [Sections, p. 325.]

APPENDI, FRANCESCO MARIA, born near Turin in 1639, son of D'Appiano, became a Jesuit, and in the Scuolo, and was after a time sent to fill the chair of rhetoric in the college of his order at Ragusa, a town which then maintained a close connexion with Italy. He became a great proficient in the Slavonian language, and he published a grammar of the language, and a dictionary of the Latin and Slavonian dialect of the Slavonians, and several treatises on the same subject. But his principal work concerns the history of his adopted country Ragusa, and it gives a very interesting account of that now almost forgotten little state, which goes far towards itself for centuries as a republic, and cultivated the arts and retained the manners of civilized Europe.

When Napoleon took military possession of Ragusa, and subverted that ancient republic, as he had subverted the republic of Venice, he found the seat of government at Ragusa, and appointed Rosaspina to be bishop of the see, and the pope retained his dignity in his own person. The republic was then occupied by the French, and subverted. When the French were driven out, the republic was restored, but the powers in Europe were now divided, and the republic was at the mercy of the most powerful nation. The republic was at last occupied by the Turks, who remained there until 1814, when it was occupied by the Austrians.

Then Appiano, who had been ambassador at the court of the Austrians, and had been a great friend of the republic, became the minister of foreign affairs of the republic, and was appointed to the post of ambassador at the court of the Austrians, and was also appointed to the post of minister of foreign affairs of the republic. He was a great friend of the republic, and was appointed to the post of ambassador at the court of the Austrians, and was also appointed to the post of minister of foreign affairs of the republic. He was a great friend of the republic, and was appointed to the post of ambassador at the court of the Austrians, and was also appointed to the post of minister of foreign affairs of the republic. He was a great friend of the republic, and was appointed to the post of ambassador at the court of the Austrians, and was also appointed to the post of minister of foreign affairs of the republic. He was a great friend of the republic, and was appointed to the post of ambassador at the court of the Austrians, and was also appointed to the post of minister of foreign affairs of the republic. He was a great friend of the republic, and was appointed to the post of ambassador at the court of the Austrians, and was also appointed to the post of minister of foreign affairs of the republic. He was a great friend of the republic, and was appointed to the post of ambassador at the court of the Austrians, and was also appointed to the post of minister of foreign affairs of the republic. He was a great friend of the republic, and was appointed to the post of ambassador at the court of the Austrians, and was also appointed to the post of minister of foreign affairs of the republic. He was a great friend of the republic, and was appointed to the post of ambassador at the court of the Austrians, and was also appointed to the post of minister of foreign affairs of the republic.
wards passed by inheritance into the house of Buoncompagni of Rome, who kept it till the French revolutionary invasion. Bonaparte, on his assuming the imperial crown, bestowed the principality of Piombino on his brother-in-law Felix Baccocchi.

(On FRIEND, Memoria Istoriche di Pisa; Botta, Storia d' Italia.)

APPOINTMENT. [TRUST AND TRUSTEE, P. C.]

APPOINTMENT. Apportionment of rent, &c. is a term of law signifying the dividing of a rent, annuity, or other payment receivable by the land or fixed personal estate, among several persons entitled to the rent, or between the person entitled to the rent and the person or persons liable to the payment of it.

The issuing out of land may be apportioned in two ways:

one by granting the reversion of part of the land out of which the rent issues, the other by granting part of the rent to one person and part to another. When rent is reserved upon a lease, and the lessor disposes of part of the lands in reversion, either by will or deed, the rent is apportionable, provided the leasee concur. But the lessee is not bound by any apportionment made without his consent. If the lessor or a stranger recovers any part of the land, or the lessor enters for a forfeiting rent, or, on the expiration of the lease, the lessee, the rent will be apportioned in respect to the part so recovered or surrendered and the part remaining in the hands of the lessee.

When a lease blinds a part of the land comprised in his lease, the rent is liable in an action of covenant for a proportional part of the rent reserved on the lease, the covenant for payment of rent being one which runs with the land; and therefore as respects him there is an apportionment of the rent. The rent of a part of the lands does not however, any more than an assignment of the whole, discharge the original lessee from his liability upon his express personal covenant for payment of the whole rent. The right of distress for the whole rent upon every part of the land of course remains unaffected by the assignment, unless, sometimes, done in the case of building leases, the original grantor agrees to restrict his right of distress on the lands aliened to a proportionate part of the rent.

If a man having a rent-charge issuing out of lands, purchases any part of them; the rent-charge is extinct as to the whole; but if part of the land out of which the rent issues descends upon the owner of the rent-charge, the rent will be apportioned. And this will also be the case upon a partition of the lands out of which the rent issues. If a grantee of a rent-charge release all his right in part of the land charged, he extinguishes the whole rent; but if a grantee of a rent-charge release part of the rent to the grantor, the residue will remain chargeable, for the same reasons deals with the rent only, not with the land. On the principles here stated a difficulty arises on the sale of part of lands subject to a rent-charge. Where the party entitled to the rent is willing to release the land to be sold, the mode sometimes adopted is that the owner of the rent-charge assigns the rent on the land to a trustee upon trust, to receive it exclusively out of the lands intended to remain charged. Another mode is for the annuitant to join in the conveyance of the lands sold and to add a proviso that the other lands shall continue liable. This plan however is open to the objection that as the proviso operates as a new grant, the rent-charge becomes liable to the incumbrances of the owner of the land created before the conveyance. A third mode, sometimes adopted, is that of the owner of the rent-charge retaining the land sold, but it seems doubtful whether such a covenant does not operate as a release of the rent-charge. If the owner of the rent-charge will not concur, the only plan seems to be for the trustee to assign the lands not sold to the other lands shall be exclusively liable, and give an indemnity by demise or otherwise against the rent-charge. It seems that the technical rule of law which is productive of so much inconvenience ought to be altered.

By the lease of a tenant for life died within the half-year at the end of which rent was due upon a lease not made in execution of a power, and which therefore determined on the death of the tenant for life, the half-year's rent could not be apportioned, and was therefore lost to both the representatives of the lessee and to the remainder-man or reversioner, upon whom the lease was not binding.

To remedy this evil it was provided by the stat. 11 Geo. II. c. 19, § 15, that where a lessee tenant for life died before the rent-day, his executors might recover from the tenant a proportionate part of the rent then owing, making all just allowances. But as this statute was construed to apply only to persons strictly tenants for life, and had no application to the case of a lease made by a tenant in fee or by a tenant in tail under a power, if in either of these cases the lessee died in the interval between the tenant for life being due, the whole rent went, according to the rule of the common law, to the heir or remainder-man, and there could be no apportionment in favour of the execut. The law has now been altered by the stat. 4 & 5 Wm. IV. c. 94, the object of which was to apply the principle of equable apportionment to all property which consists in periods and fixed money payments.

By the first section it is declared that rents reserved a leasehold for a term of years on the death of the person so reserved (though not strictly tenant for life), or on the death of the tenant per autre vie, shall be considered as within the provisions of the above-mentioned stat. 11 Geo. II. c. 15, § 15.

By the 2d section it is enacted that from the passing of the act all rents reserved service reserved upon any lease by a tenant in fee, or for any life interest, or by any lease granted under any power (and which leases shall have been granted before the passing of this act) or by any annuities, pensions, dividends, moduses, compositions, or all other payments of every description in the United Kingdom of Great Britain and Ireland made payable or coming due at stated periods under any contract that shall be executed after the passing of this act, shall be apportioned and in such manner that on the death of any person interested in any such rent, annuities, pensions, dividends, compositions, or any other payments, as aforesaid, or in the estate, fund, office, or Messrs from or in respect of which the same shall be issuing or derived, or on the determination by any other means whatsoever of the interest of any such person, his executors, administrators, or assigns shall be entitled to a proportion of such rents, annuities, pensions, dividends, moduses, compositions, and other payments, according to the terms which shall have elapsed from the commencement or last period of payment thereof respectively (or at the death of such person, including the day of the death of such person or of the determination of his or her interest, all just allowances and deductions in respect of charges on such rents, annuities, pensions, dividends, moduses, compositions and other payments being deducted, whether the death of such person be before or after the passing of the act).

A tenant for life, as respects the year or years during which he is in life, is liable, for the part of the rent due during such period, to be recovered by any person entitled to the whole rent. The annuity, if any, or other annuities, pensions, dividends, compositions, or other payments being deducted, whether the death of such person be before or after the passing of the act, shall be apportioned and in such manner that on the death of any person interested in any such rent, annuities, pensions, dividends, compositions, or any other payments, as aforesaid, or in the estate, fund, office, or Messrs from or in respect of which the same shall be issuing or derived, or on the determination by any other means whatsoever of the interest of any such person, his executors, administrators, or assigns, shall have such and the same rights, and have and enjoy all the same privileges and be subject to all the same duties and liabilities to law and in equity for recovering such apportioned parts of the said rents, annuities, pensions, dividends, compositions, or other payments, as aforesaid, as if such rents, annuities, pensions, dividends, compositions, or other payments had been paid, and been in the hands of such person, into whose hands they would have come had there been no death or determination of his or her interest in the same, and shall be entitled to recover any rents reserved or payable reserved by any lease or demise, and the land, tenements, and hereditaments comprised therein shall not be resorted to for such apportioned parts specifically as aforesaid, but the entire rents of which such portions shall form a part shall be received and recovered by the person or persons who, if the act had not passed, would have been entitled to such entire rents; and such portions shall be recoverable from such person or persons by the parties entitled to the whole rent, in the same manner and to the same extent as any rents, annuities, pensions, dividends, compositions, or other payments. It seems doubtful whether the above enactment will apply to the case of an annuity payable at certain periods and determinable at the death of the grantor, because if the annuity cease by the death of the grantor on any day before that of payment, the 'entire portion' can never become payable. It is advisable therefore to retain the usual apportionment clause in the grants of such annuities.

The 3rd and last section provides that the act is not to apply to any case in which it shall be expressly stipulated that no apportionment shall take place, nor to annual sums made payable on policies of assurance of any description.

Rights of common are apportionable in certain cases. Common of pasture when the common is neither a common owned either where the commoner purchases a part of the land in which he has the right of common, or upon an alienation of part of the land to the right which is appurtenant. In the case of common of pasture appurtenant, there will be apportionment in the second case, but not in the first. Common of
of male flowers axillary, umbelliform; the female ones aggregate. It is a native of North America, from Canada to Virginia, in sandy wet woods, and on the borders of swamps.

The flowers are white, and the berries are of a crimson red. The bark is bitter, and has been substituted for Cinchona bark in the treatment of fevers. It is said to act as an antiseptic, and is used in America as an application to gangrenous sores, and also in infusion or decoction, as a lotion in cutaneous disorders.

In plader, has evergreen, cushion-like, ovate-shaped, shining leaves, a little toothed at the apex, and axillary 3-flowered pedicels. This is a low handsome shrub, with white flowers and a black fruit; hence it is called, in Jersey, ink-berrys. It is a native of North America, from Canada to Florida. It has been introduced into Bath, for the use of those for the Paraguay tea-plant, and are used for making tea.

There are several other species of Prinos, some of which are hardy, and well adapted for shrubbries. They will thrive in most light soils, but do best in peat. They may be propagated by laying down the shoots or by seeds. Most of the species of Aquifoliacese plants may be cultivated in the same manner.

(Don, Gardner's Dictionary; Burnett, Outlines of Botany; Lindley, Natural System.)

AQUILLA, JULIUS, a Roman jurist, whose period is uncertain. He is one of the jurists who were used for the composition of the Digest. As there is a doubt whether there be only one Digest, or whether it is a collection made from two, the Digest contains only two excerpts from him, both of which belong to his 'Book of Answers'— Liber Responsorum' (Dig. 25. tit. 7. s. 54; tit. 10. s. 12).

AQUILLARIA/C/E, a small natural order of plants belonging to Lindley's tuberosous groups of incomplete Exogen. The species are trees with smooth branches and a tough bark. The leaves are alternate, entire, seated on short stalks without stipules, and when young with a pubescent underside, with very fine veins running together into a marginal vein just within the margin. The calyx is tubulous or tubular, limb 5-cleft, segments spreading, persistent, with an imbricated aestivation, the ovary furnished with 5- or 10-bearded scales (metamorphosed stamens). The stamens are 5 or 10 in number; when 5, they are opposite the segments of the calyx; the filaments are short or absent, smooth, inserted into the orifice of the calyx a little lower down than the scales, except in cases where they are united to the tube of the calyx; the anthers are narrow, oblong, attached by their back edges to the middle, 2-celled, opening internally and lengthwise; the ovary is superior, sessile, or stipitate, downy, compressed, 1-celled, having 2 thickened sides, a line of prominent stigmata resembling a dissepiment, hence apically 2-celled, with a very narrow partition; ovules two, of which one is suspended from each placenta, tapering downwards; the style is either absent or conical and thread-like; the stigma is rounded, or large, sessile, or stipitate, 1-celled, 2-valved, the valves bearing in the middle the placenta, which almost touch each other. One seed is mostly borne on each placenta (one is sometimes abortive); the seed rises up by the aid of a funiculus, originating near the apex of the placenta, and is furnished with a tail-like aril, which descends straight from the hilum to the bottom of the capsule; the radicle is straight and superior, the albumen is absent, and the cotyledons thick, dead, and hairy. This order, which consists at present of only three genera, was constituted by Robert Brown, who regarded it as having so close an affinity with Chilaleteace as to see no objection in making it a separate order. On account of its peculiar connection with Thymelaeaceae, in which he followed Lindley, who says, 'Aquillariaceae chiefly differ from Thymelaeaceae in their dehiscent fruit, and probably also in the direction of their radicles. In both orders the ovary is superior, bilocular and 1-celled; the fruit is a small scale-like berry at the end of a stalk, the orifice of the calyx, and no petals; both suspended ovules, one single style, and single stigma.' De Candolle places the order between Chilaleteace and Terebinthaceae.

All the species of Aquillariaceae are natives of the East Indies.

The three genera of this order are thus defined:

1. Aquillaria. Perigone 5-cleft, urceolus 10-lobed, stamens 10, anthers versatile, style none, seeds covered by a spiny substance.

VOL. I—8
2. **Perigonea**. Perigone 6-petalled, urceolus 10-lobed, stamens 10, anthers oblong, seed furnished with a wing.

3. **Gyrinopsis**. Perigones tubular, toothless; seed furnished with a spiny, awl-shaped, trigonellate tail.

Of the last two genera little is known. One species of each has been described. There are three species of **Aquilaria**.

A. **Malacca**. The **Bois d'Aigle**, or Eagle-wood, has ovate, abruptly cutinized leaves. It is a native of Malacca, and produces a whitish yellow wood. This is the A. of commerce and the native of the East Indies, where it is called *Ugoor*, or *Ugooro*, by the natives, and *Lignum-aloe*, or Aloe-wood, by the Europeans. The wood has a fine scent, and is supposed to be the *Calamumb*, or *Aguillochum*, of the Spanish.

**Aquilaria Aesculacea** is another species which also yields a scented wood, and has been known in the Medici Medicus, and used in perfumery, under the names of *Agullochum*, *Aesculaluminum*, and *Aloe-wood*, by the Europeans. In a healthy state this wood is said to be white and inodorous; but it is subject to the attacks of disease, which causes the secretion of a resinous matter, and the wood then becomes coloured, and gives out a powerful scent. This secretion resembles camphor in many of its properties, and has a bitter flavour, hence its medical value. It is recommended in the same diseases as the febrile and volatile oil, and does not seem to possess peculiar properties; so that it is not used as a medicine in Europe. The Cochinn-Chinese are said to make their paper from the bark of this tree. The scented woods of **Aquilaria** and many trees must not be confounded with the *Aloezyon Agullochum*, or Aloe-wood, which is a tree belonging to the natural order Leguminosse, and which also yields a scented wood used by the Chinese in medicine and perfumery.

**ARABA**. The war of Mehemd 'Ali, pasha of Egypt, against the Wahhabis, the occupation of Aden by the British, and their friendly connections with the Imam of Muscat, have greatly contributed to increase our knowledge of Arabia. In consequence of those events the attention of Europe has been directed more eagerly towards that country, and as the Red Sea now once more offers a passage from Europe to India, we may hope that one of the most interesting portions of the globe will soon become better known. The natives of Arabia have always shown hostile feelings towards Europeans. These feelings may have increased among a few tribes, but generally speaking they have diminished. The intercourse of the British with the Arabs will probably prepare the way for Arabic translations or abridgements of European works on scientific subjects, especially natural philosophy, chemistry, medicine, mathematics, navigation, and generally useful knowledge, so that the Arabs may learn to know Europeans, and we may become better acquainted with them. The coasts of Arabia are now accurately known, except some parts of the south-eastern shore, on the Indian Sea, and even on those we are at the positions of the principal ports. The splendid chart of the Red Sea by Commander R. Moreby and Lieutenant Carless, in two immense sheets; the chart of the south-east coast of Arabia by Commandier Haines, assisted by Lieutenants Welford, Sanders, Jardine, Shepherd, &c., and the chart of the Gulf of Persia by Commander Barnes Brucke, in two great sheets, ought to be studied by all those who wish to make themselves acquainted with the approaches to the most important country that lies between Europe and India. A person will be greatly assisted if he consult the atlas with the aid of Adjutor's 'Geographical Directory,' London, 1836, 4to. The best map of Arabia is that of Bergsma, Gotha, 1835. In some places this map is too crowded, so that in spite of the minuteness of the engraving the eye is unable to detect the features of the country. This defect is less owing to the number of places and names than to the amount of hydrographical and orographical delineation, and we find the same defects in other maps of that distinguisable geographer, as for instance in his map of Cibra. Frequently with the aid of Birds are extremely inexpressible, such an unexperienced person might be induced to believe that what he sees is as accurate as it is neat, but this is not generally the case. In making maps minuteness of execution should always be preferred.

If the map of Arabia is half turned so that the western side shall be nearest to the spectator, the eye will traverse the country from west to east, in the direction of the parallels, and not from south to north, in the direction of the meridians, in which lies the general construction of the maps leads us to examine them. On viewing Arabia from the Red Sea we perceive an immense range of mountains stretching from north-west to south-east, nearly parallel to the coast of the Red Sea, and generally not far from it. In 21° 20' N. lat., 41° 16' E. long., near the mouth of the Teyf, and at a distance of 64 miles from Mount Sinsai and the Straits of Bab-el-Mandeb, a chain detaches itself from that range, and runs north-eastwards towards the Persian Gulf, and it becomes gradually lower. This is the Jebel-'Ared, or the Jebel-Sammur, a range of mountains parallel to the great range along the shore, and is the latitude of the peninsula, which it divides into two great portions, the one north-west of it, the other south-east. The northern portion is divided into two by the Jebel-Shammur, commonly called the Agerit, and the Jebel-Sammur, the Mount of the Elamites, it stretches from west to east between 28° and 29° N. lat., and probably connected with Mount Sinsai by intermediate chains, such as the Jebel-Adam and the Jebel-Sallani, the position of which however we do not precisely know. The Jebel-Shammur is said to be as high as Mount Lebanon. The portion north of Jebel-Shammur comprehends ancient Arabia Petrae in the west, and the greater part of antient Arabia Deserbi in the east; the most elevated parts are the tracts north of Mount Sinsai, and east of the Teyf, and the 6 Pales, which form a ground slope towards the northern corner of the Persian Gulf. The tract north of Jebel-Shammur is a sandy desert, intersected by some arid wadis, or valleys, with running water, or only a few wells and moist spots where water may collect, and forms a great desert formed by the wandering of the traveller against the scorching sun. Lying between Palestine and Syria in the west, the Euphrates in the east, and the more fertile districts of Arabia in the south, it is traversed by several high roads. One of the most important leads from Haleb to the Euphrates and thence to Bagdad, by Tabeb, and the Wadi-Sulib; and from west to east it is traversed by the road from Damascu to Bagdad through the oasis of Palmyra and the Wadi-Hazrak, a valley stretched in winter by a chain of intermediate mountains towards the direction of the Euphrates. The tract which is traversed by these roads is generally considered to belong to Syria, although it has the Arabian character, and is inhabited by genuine Arab tribes. The road from Bagdad to Anhef, and thence to Mecce and other parts of central Arabia, crosses the highest portion of Jebel-Shammur. The road from Damascus to Jebel-Shammur, and thence to the interior of Arabia, goes in a south-east direction, following the sinuosity of the Wadi-Ades-al-Shirhan for about 160 miles, and traversing the fertile plain of Jof and the desert plain of Ed-Dhibah or Ta'ta before it reaches El-Shammur. Two western roads lead from Damascus and Jerusalem to the Gulf of Aekib and to Medina. In the direction from the Dead Sea to Jof is the easternmost of these, and which is called by the natives the ‘wilderness,’ or Barib-al-Abad. This road to the interior is not very elevated, mostly level, traversed by chains, and intersected by valleys, of which we have only vague notices. This observation however does not apply to the group of Mount Sinsai. The portion south of Jebel-Shammur extends east as far as the Persian Gulf, and is bordered in the south-east by the Jebel-'Ared, and on the west by the great range mentioned above, so that the tract between this range and the coast does not belong to it. The country is a high table-land inclining towards the west, and not much equal to the proportions of the Persian Gulf. In 26° N. lat., 46° E. long., a chain of mountains, the Jebel-Tidek, detaches itself from the Jebel-'Ared, stretching north-west in the direction of the Jebel-Shammur. The tract west of the Jebel-Tidek, an irregular mountain, is watered by the portion east of it, which loses the character of a table-land in proportion as the traveller approaches the Persian Gulf. The immediate neighbourhood of which the country is low and sandy. The greatest part of the inland tract south of the Jebel-'Ared is, generally speaking, unknown. It is probably a table-land as high as the tract north of that chain, and its inclination is likewise towards the Persian Gulf, the direction of the slope being north-eastwards, in the course of the higher northern range, with the range along the Red Sea by a high tract and some ridges of hills, stretches parallel to the coast of the Indian sea in a north-east direction, separating the elevated lands in the interior from the coast country. This chain also is at right
angles to the range along the Red Sea, and is consequently parallels to the Jabel-’Ard. From its most eastern part a chain branches north-west, at right angles, and its direction is parallel to that of Jabel Tulsik mentioned above. This branch chain rises above a plateau of great elevation, and several of its peaks, among which Jabel-Gassiri, or Ghasiri, as Edrfi writes it, is the highest, are said to be crowned with eternal snow. The town of Tayf stands at the western foot of Mount Gassiri; and although the immediate neighbourhood and the deeper valleys produce the choicest fruits, especially excellent raisins, the surrounding plateaus are so high that the water will freeze in the summer nights. From the highest peaks being always covered with snow in 21° N. lat., we may safely conclude that the Jabel-’Ard is the highest of Arabia. From Tayf the range continues its south-eastern direction as far as a point about 19° 31’ N. lat., where it forms two branches, one stretching south, and lowering gradually till it reaches the coast of the Red Sea in about 18° N. lat., and the other south-westwards, and forming the western boundary of the sea. Between the two chains is a deep valley running from the north, where it is highest, towards the south, where it becomes broader, till it widens into an open plain. This valley is the national boundary between the provinces of A’dr and it lies between the province of A’dr and the south (Tehmah) of Konfodah in the west. One of the most important mountain-passes of this range leads through the valley, and the road high from Konfodah to A’dr, and farther on to the interior of Arabia. The point where the two chains originate seems to be a plateau of great elevation; the road from Konfodah leads over it, and it cross here by another high road leading from the lowland of Hejaz to the northern-east part of Yemen (A’dr), through which the Egyptian army penetrated into Baghdad in 1836. The natural boundary between Hejaz and Yemen, and the limit between the range of Hejaz in the north and the range of Yemen in the south. The northern commencement of the great western range is the lofty peak of Mount Sinai. A deep inlet, the gulf of Abab, separates it from a high chain stretching along the northern coast of the Red Sea as far as Yambö. The bold and craggy summits generally press close upon the shore. It has no general name. Along the gulf are the Jebel-Ashš and the Jebel-Tihib, the latter 9000 feet high; south of them are the Jebel-Antina, Jebel-Ab, or Amr, on account of its elevation, the most remarkable, which and of the coast is a low and sandy tract; but its northern and western parts tower above the shore, and are known by the names of Jebel-Nab, Jebel-Lambam, and Jebel-Hadi. Yambö, at the foot of which lies the sea town of Mäilah, is between 5500 and 6000 feet high, and, with two other peaks in the neighbourhood, is visible from 60 to 80 miles. Mäilah lies in 27° 40’ N. lat. Six miles south-west of it is Ast-Salah, a high promontory, which on Ptolemy’s Chart of the Red Sea is nearly 40’ south of Mäilah; and this error has been copied by many navigators. The prevalent rock of the whole chain is porphyry, rising with craggy serrated summits above a base of metamorphite. Yambö, the port of Medina, lies on the northern side of a bay forming a spacious, deep, and safe harbour. It is the jumping-off point of and known in the history of geography ever since Ptolemy ascribed it to Ibn Habs, being 24° 6’. The present name is Yambö, or Yambö, or Yambö, which is Yambö, or Yambö, or Yambö, which is a corruption of Jabel-Rafid, as far as the promontory Rás-eh-hat-bah, in 23° 30’ N. lat., continues parallel to the coast, but is at some distance from it. The tract between it and the sea is however mountainous, being traversed by portions of the great range, and terminating abruptly towards the coast, from which it is separated in some places by narrow sandy tracts, while in others it forms bold promontories along the coast. Such is the Rás-eh-hat-bah, the last of a chain of isolated mountainous tracts, which form in the middle of some of the principal rivers of the Arabian desert. The names of the great range from north to south are—Jabel-Sahr, which contains lofty peaks visible from the sea; Jebel-Sab, or Sabah, 4000 feet high; Jebel-Aly, and Jebel-Rafid, in the latitude of Rás-eh-hat-bah the range takes an eastern direction, and afterwards running south, forms a bend which surrounds the high tract of Mecca, which is about 100 miles wide from west to east. This crescent-shaped bend, the Jebel-Kašr, is the highest portion of the whole range and it is watered by the river El-Haas, which rises above a plateau of great elevation, and several of its peaks, among which Jabel-Gassiri, or Ghasiri, as Edrfi writes it, is the highest, are said to be crowned with eternal snow. The town of Tayf stands at the western foot of Mount Gassiri; and although the immediate neighbourhood
of the strait of Bôo-el-Mâdheb, between the cape and the coast of Abyssinia, is about 14 miles; the island of Perûn, or Mehum, divides it into the great or western channel, which is 106 miles wide, and in the middle above 100 fathoms deep, and the little or eastern channel, which is 3 miles wide, and never less than 13 fathoms deep.

The great range stretching from Southern Yemen north-east to 'Oman is very imperfectly known. From Jebel-Yafâl a chain stretches east near the coast, rising by several terraces to 2500 feet above the sea, and is traversed by a ravine called Nakab-el-Hajar. There are many large rivers, and several smaller ones, which are also traversed by this chain. These terraces are formed under the names of Jebel-Hamari, and Jebel-Ghurâb, which are in the country of Hadhramait, parts of which have been visited by Wellsted and the author. This chain has a range of from 8 to 10 miles, and is intersected by some ridges of hills, and intersected by wadis of wide depth.

The interior of Hadhramait was entirely unknown to Europeans until it was lately visited by the Baron de Wrede, a German gentleman, whose account has been published in the fourteenth volume of the 'Journal of the Royal Geographical Society of London' (1844).

The baron having been robbed of most of his papers by order of the Sultan of Seiff, the account is very short; but his description corresponds generally with the accounts of Edward Arbery, and信息安全

The north-west is traversed by a range of mountains in the direction of Makalla, which is a chain of hills extending for about 60 miles from the coast. On the fifth day he ascended a high yellowish plateau about 8000 feet high, the eastern part of which was overflowed by the summit of the colossus Kar-Scebn.

The appearance of the sea as far as the eye could reach was from west to north-east. Iron-sandstone was observed on the whole plateau, overlaid by a yellow and hard sandstone of a fine grannular texture; and the plain was traversed by ridges of hills with conical summits, and intersected by deep and narrow ravines (wadis), through which the rain-water flows into the lower regions.

On the ninth day the traveller reached the Wâdi-Dûân, the chief object of his search, which, from its commencement about 150 miles north-west from Makalla, stretches according to all appearance (the baron does not give its direction), east, south-east, and south, till it reaches the sea near Sâhibi, a small village about 140 miles north-west from Makalla. The baron was only allowed to visit the upper part of this celebrated valley, which has different names in different places. Following the opinion of Niebuhr, our best geographers have put the Wâdi-Dûân 850 miles north-east of Makalla, in the unknown desert north of the country of Shêher, though Seetzen observed that it was on the east side of the desert of Hadhramait, which, according to the same traveller, begins five journeys from Makalla. Seetzen's further description of the valley of Hadhramait corresponds with that which Baron de Wrede gives of the Wâdi-Dûân; and as both agree that the Wâdi-Dûân, which is the most celebrated for its length, is a branch of the valley of Hadhramait of Seetzen, and the Wâdi-Dûân, in a more extensive sense, of the baron, we conclude that in this case Niebuhr and those who followed him were wrong.

The difference in the journeys from Makalla, the beginning of the Wâdi-Dûân, is no absolute difference of distance, since the baron made the way in eight and a half short journeys, each of less than six hours, while the five journeys of Seetzen might be longer journeys. From Khoreibeh, a town in the Wâdi-Dûân, Baron de Wrede travelled by the route of Wâniheb, which is the northern part of a long valley bearing the successive appellations of Wâdd-Håger, Wâdd-Giswuel, and Wâdd-Mafiah, under which name it reaches the sea near Bir-el-Hali. This is the Wâdd-Mafiah which was visited by Wellsted on his tour to Nakab-el-Hè'far. Near Hoti, a town in the Wâdd-Hâger, the valley is watered by a continually running stream that rises four journeys north-west from that town, and of course continues its course through the Wâdd-Mafiah, as the author has described it appearing from the neighbourhood of the Wâdd-Mâreh, and is perhaps the same by which this fertile valley is watered, and which supplied the famous reservoir of Sâba or Mâreï. We thus come to the country of Hadhramait, and the first great long rivers, one originating not far from Wâdd-Mâreh, and running south-east and south for a distance of about 150 or 160 miles; and the other, the river of Dûân, flowing east, south-east, and south for nearly 800 miles. But neither of them reaches the sea, which is the case with nearly all the rivers in Arabia; and it may be doubted if they flow during all seasons, though it is possible that they never dry up entirely in all places.

From Khoreibeh the baron travelled six good journeys north-west and west to Sava, in the Wâdd-Râchî (Rakki), which is the present capital of the country, in 17° 11'. He remarks about the river: no accurate computation is possible. This Wâdd runs north eight journeys. A six hours' journey north-west brought the traveller to the edge of the desert El-Ahkâf, called Bahr-el-Saffi, one of the most extraordinary tracts on the earth. It lies not far from the borders of the desert, and is 1000 feet below the level of the high land (from which the baron descended), and strewn with numberless undulating hills, without any trace of vegetation. There are many spots that indicate the limits of old vegetable mould, and the sea, the traveler, having thrown a plummet of about one pound weight attached to a cord of sixty fathoms into one of these sand-gulls, which was about two miles long and nearly as broad, saw it sinking with diminishing velocity for about five minutes, when the end of the cord disappeared in the chasm.

The baron says he made the experiment in the most northern chasm, from which we must conclude that Bahr-el-Saffi, that is, the tract containing such chasms, is more to the north from the spot where he reached the edge of El-Ahkâf, than Bahr-el-Saffi is the border of El-Ahkâf, stretching from the spot where he reached it to Kubr-el-Hûd, a distance of eight journeys; and, as, according to his statement, Kubr-el-Hûd is 17° from the equator, it is evident that Bahr-el-Saffi is traversed from south to north by the Wâdd-Râchî, and is consequently as difficult to be traversed as the desert of Saffi. From Mahrab, which is called Sâhib or Dâshir, by the Arabian geographers. Bahr-el-Saffi, or the sea of Saffi, or the former Bar-el-Saffi, or desert of Saffi, is said to be called so on account of Saffi, an Arabian king, having perished there with his army in his attempt to march through it. His fate reminds us of Aelius Gallus, who, on his retreat from the interior of Arabia towards the sea, has been visited and described by the baron. Parallel chains of mountains run along the coast, pressing in some parts upon the sea, and separated from it by narrow sandy tracts. Makalla lies in 14° 31' N., 46° 50' 30" E., long., in the corner of a fine bay, and is situated in the extreme part of the greater branch of the bold promontory, in 16° 37' 30" N., 49° 58' E. long., visible at the distance of 26 leagues from the sea. Ras-Morebâst, a low cape east of Ras-Tartik, is in 16° 56' N., 52° 31' 35" E. long., according to Capt. Owen. East of it, a high tract borders the sea, being a terrace leading to lofty and steep chains, which stretch in the same direction, and are visible from the sea at the distance of 20 leagues. Their height has been estimated at 6000 feet.

The interior has the name of Wâdd-Dûân, and is that part of the valley of the same name to which it generally is, though erroneously, called Mahrab. The language of this tribe has always been, and still is, very different from the Arabic, being probably derived from the ancient Hamitic language. The country of Shêher is described as an awful desert, but the mountainous tract along the coast is fertile, and in many places the mountains are covered with forests, a rare circumstance on this coast. At Ras-Tartik the coast turns north, keeping that direction for about 60 leagues, in which place the baron was prevented from proceeding by a great mountainous projection, which is as far as Ras-Morebâst; thence it runs north-east and north about 90 miles; and again running east about 60 miles, encompassing the Gulf of (Jûna-1-) Hashish, or Kuria-Muria, which is the name of a group of great islands, the passage of which is entirely prevented by two extraordinary reefs of coral. From this point the direction of the coast is north and north-east,
but its details are not known. Opposite it lies the long
land of Masearah, the eastern coast of which has been
surveyed. The coast terminates to the north-east with Râs-Jin\', a
high promontory, backed by a chain of lofty mountains, in
22° 30' N. lat., and 36° 10' E. long.: this is Râs-Katîf, a low point,
where Bahr-Omân begins, or the part of the Indian Sea
which lies between the coast of Omân and the coast of
Beyanistan. From Râs-Katîf the coast of Omân turns west
and south-west, and is smooth and sandy. The coast
lies between that cape and Râs-Hasrân, near Muscat;
the other, which has a chord of 240 miles, and advances to the
sea as far as 26° 21' N. lat., 56° 30' E. long. (in the map of
Evans, 1850, the Medina runs west from Râs-Katîf to Râs-Hasrân.
The Strait of Ormus, between this cape and the coast of Persia,
is about 32 miles wide at the narrowest part. The coast of
Omân is generally low, being a narrow "telaham," backed by
lofty chains of hills. Near Muscat rocks tower above the
sea. Jebel-Huthur, in the south-east, is said to be 6000 feet
high; and its north-west continuation, Jebel-Akadar, has an
equal elevation: a peak which is south-west of this chain is
still higher. Still farther west begins the sandy table-land.
Part of this tract is called El-Tehabat; it is unknown to us:
it is said to be inhabited by a tribe called Zarâk, whence
comes the word Sarascas. Omân is generally a fertile well-
cultivated tract, though containing sandy districts, as we see
from the description of Wellsted.

The coast of Omân distinctly turns south-west, and
continues in that direction for about 200 miles along the
Persian Gulf; the peninsula extremity of Arabia, between
that gulf and the Gulf of Omân, is about 170 miles broad at
its base, and nearly as long from south to north. From the western
continuation of the coast of Persia and south-west of Râs-Katîf
and then north for 140 miles, as far as Ras-Anfr, forming an immense bay, the shores of which are generally flat,
with an irregular outline, intersected by numerous creeks
and small harbours, and lined by numerous islands and coral cliffs.
Prates have always infested this dangerous coast, and they
are not yet entirely destroyed, in spite of the vigilance of
the officers of the British Navy. From Cape Anfr the coast
again runs south, which direction it keeps for about 80 miles,
reaching the coast of the Persian Gulf. Between this
bay, the Gulf of Bahrein, in the middle of which lies the
large island of Bahrain, noted for pearl fisheries. The coast
round this gulf is indented by many smaller bays and creeks,
which have good and safe anchorage, and the whole tract is
one of the most frequented of Arabia. A little south of Râs-
Tâmir, lying at the north-western extremity of the gulf, is
the town of El-Katif, in a fertile and well cultivated tract,
bordered on the west by the desert, and noted as a commercial
port and a centre of the pearlfishery. It is a well fortified and defended by a Turkish garrison, the com-
mander of which depends upon the Pasha of Barnath.
The town of A'zirj or Adnbar, once in the possession of the
Wahhabsies, is also a centre of the pearlfishery. El-Derâriyyeh, is supposed to be in the innermost corner of
the gulf, which is here called the bay of El-wah. From Râs-
Tâmir the coast runs in a curve north-west, north, and
then east, up to the Shat-al-Arab, forming a great number of
small bays, which are dangerous to approach on account of
near coasts and reefs. The tract along this coast, or the
northern part of El-Hassâ, is flat and covered with sand to a
great extent, but it also contains many fertile and well culti-
vated valleys.

The interior between El-Katif and El-Derâriyyeh, has been
made known to us by Captain Sadler, the first European who
traversed Arabia from one coast to the other; and the
tract from El-Derâriyyeh to Medina was seen by the same
traveller and the French officers who accompanied the
expedition of Ibrahim Pasha against El-Derâriyyeh, the former
capital of the Wahhabsies. But all that we know of this tract is
chiefly confined to the routes or is derived from the descrip-
tions of Jamal, who mentions, El-Derâriyyeh, and a well
cultivated district, of the Persian Gulf towards the interior.
The first terrace begins about 100 miles westward from the coast, where Sadler felt a cooler atmosphere, but the ascent is gradual. The country
is generally barren, being a rocky soil covered with pebbles or
rocks, and the only cultivated tracts are the few more fertile tracts at some distance from the common
road. The second terrace begins in the neighbourhood of
Derâriyyeh and Misrah, where the high land is cut by fertile
valleys covered with date-trees; the plains afford excellent
pasturages for horses. Derâriyyeh, though destroyed by
the Egyptians, is a place of importance and has always had a
large trade, being a central position, and connected by great
roads with all the provinces of Arabia. West and south-west
of this town are the highest portions of the central table-land
of Arabia, and approach to Mecca. The most direct route
to Anfezah, where it joins the high road from Beighâd and Damascan. The position of Anfezah is as
important as that of Derâriyyeh; it is in the province El-
Kusn, at nearly equal distances from the Persian Gulf and
the Red Sea, west of Ris-Musendom, and north-east of the province El-A'reed, in which Derâriyyeh
is situated; the tract between this province and El-Kusn
is the province of El-Wahsh. The road from Anfezah to
Medina runs by a series of chain of ranges which stretch
from north to south, thence across other barren hills called
Jebel-Tayeh and Jebel-Maqiyeh, as far as Henkâyeh
(Henfah) in the neighbourhood of Jebel-Ohod, a mountain
of red granite, yet it turns south-west south of Medina and
passes through a desert which is a stony plain traversed
by chains of barren rocks and sand-hills. Water is not
scarce, but there are few villages, and the cultivation of
the more fertile tracts is neglected, probably in consequence
of the Wahshah war. Henkâyeh is placed in Gunthorpe's
map 36 miles north-east of Medina, in 26° 22' N. lat., 38°
E. long. The account of Sadler of this part of his
route is very incomplete. In the map belonging to Burck-
hardt's Travels, Henkâyeh lies in 26° 35' N. lat., 38°
E. long. From Henkâyeh to El-Burckhardt's Travels,
20' E. long.; Berghaus computes it to be in 26° 9' N. lat.,
38° E. long., 75 miles north-north-east from Medina, and he
seems to be more correct than the others; Houghton is
apparently at fault. As far as the map of Wellsted, the
transaction of Henkâyeh is of great importance; the road from
Anfezah to that town is evidently the high road to Medina
as well as to the upper part of the Red Sea; the former
branches from that place south, the latter continues in its
western direction.

The axis of Arabia, the range of El-A'reed or Jebel
Imariyyeh, begins, as above mentioned, in the environs of
Dayef, where it is connected with Mount Korah-Karah, which
is part of the Hejaz chain, by the lofty peak of Qasdiân
the surroundings of which are termed the Derâriyyeh. We
know it only from the descriptions of the natives and
some Arabic writers, but D'Anville placed it in his map of
Arabia. Its north-western declivities are steep, white rocks
rising like a gigantic wall, along the foot of which runs the
dayef from Derâriyyeh to Mecca mentioned by Edrizi, and
which is marked with its stations on most of our maps. In
the south-east this chain borders on a sandy table-land, and it
seems that the great gap which, according to Ritter's opinion,
it is supposed to be the gap of the supposed route of
El-Derâriyyeh, runs across that table-land at some distance south-
west of the chain of El-A'reed. There is another road, first
mentioned by Baron von Hammer, who derived his know-
ledge from the maps of Berghaus, which runs from Mecca by Merak, Shik, Jenkijj, Merakb, Menahb, 'Ahlâb, Sekiyeh, and Dhat-
'Ark, where it joins the northern road: it runs south-east of, and generally parallel to, the chain
of El-A'reed. But whether those places are situated on the
table-land between the chain and the supposed gap, or in the
gap or valley, we cannot determine. The road is not
mentioned in any of our maps. The town of Derâriyyeh, which
is known to us by the descriptions of the natives as being
situated in or near the western part of the Derâriyyeh (as in
the map of Berghaus), is most probably on that road
which continues from that place south-west to Mecca, while
another road, which has a southern direction, traverses the
fertile and well cultivated district of El-Bakars, and leads to
'Asir and the other districts of Northern Yemen. The pro-
vince of 'Asir is traversed from west to east by four consider-
able streams which unite in its eastern part and form the river
Bisbes, which, according to a brief account lately published
by Mr. Jomard, contains the town of Deir-El-Bakars, a distance
of about 200 miles. Jomard thinks that the river Afân, which according to the Arabian geographers
traverses the province of El-Hassâ from west to east, and
empties itself into the Persian Gulf somewhere below El-
Afân, is the continuation of the river Wâdi, which flows in the
valley of Derâriyyeh flows into the Wâdi-Afân, and we
can trace this Wâdi still farther to the west. Niebuhr
observed that there was no perennial stream in the Wâdi-
Afân, nor has Captain Sadler, who twice crossed the line in which
the Afân was supposed to flow, observed anything like a
river in that tract. On the other hand, it is difficult to explain where the river Bisheh finally flows to. Its direction is certainly north-east, and the natives say that it enters the Persian Gulf. It is supposed by some that it flows into some lake, and such is the lake Salome, which, according to the account published by Jomard, is east of the Wâdi-Dowarâ, and into which the river Bisheh flows after having wasted that Wâdi. It flows farther down—a phenomenon observed in other rivers. The same account, which is derived from trustworthy natives, also says that the Bisheh, after having traversed the lake, continues its eastern course and empties itself into the Persian Gulf. It is probable that this road is still frequented, but leads through barren tracts inhabited by a warlike population. Another road was formerly known between 'Oman and Dâwarâ, where there is a frequent road from all parts of Arabia, and even of India. Burckhardt mentions a path to the town of Nejd, through the Wâdi-Jebrin, to Hadramaut, which is frequented in summer. This road must cross the Bahur-ul-Saff (the northern and western barrier of Hadramaut), and a considerable rise in the relief. Wrede, the English traveller, supposes that this road was used in the Wâdi-Rachie, but through the Nejd road also, though, of course we do not mean the sand-gulls. It is said that an English gentleman has lately started for Southern Arabia, with a view of traversing it in its whole width across El-Ahkaf. That road is little frequented. Wrede, the English traveller, supposes unless prevented by the natives. The whole tract seems to be inhabited by Beduins or Nomadic Arabs, and there is little chance of finding towns or many fixed settlements. The maps attached to the editions of Ptolemy have induced many to believe that he was acquainted with a number of towns in the tract which is now called El-Ahkaf; and Jomard, excited by hopes of making conquests in the desert, thinks that if we knew all Arabia, our maps of the desert would be so much the poorer. This is far from likely. Ptolemy had certainly a more extensive knowledge of Arabia than any other ancient or modern geographer, but his knowledge was not accurate, and if we should succeed in clearing any part of the desert, it is more probable that his map would be little more correct as our own must be little more. We should be like his. The writer has in his possession a vast number of extracts from Arabic geographers and historians who have never or seldom been made use of for geographical purposes, and the works of others are still in the present stage of preparation. He has also a number of extracts from Ptolemy's map, which will be of great use when the corrected and the corrected, the corrected, the corrected.

The remaining part of the interior of Arabia, between 'Oman and Nejd and Hadramaut, is a tract of which we have no knowledge. It is generally believed to be a desert overgrown with salt grass and desert shrubs, although in the Jihâd-usûm of Hâjji Khalil it is described as an interrupted wilderness, inhabited in some places, so that the traveller is always sure to sleep at night in a hut. It is called El-Bisheh, because it contains many barren tracts covered with sand-hills, but this term is frequently employed by the Arabian geographers in the description of other parts of Arabia. The unknown part of Southern Arabia begins at the Wâdi-Rachie, in the west, in about 46° 30' E. long. That meridian forms its limit as far as 30° N. lat., in the north-eastern corner of the Wâdi-Ahâj. A line drawn from that spot north-west to the eastern boundaries of El-Bakrâ was mentioned above; hence north-east along the range of El-Arkâs far as the meridian of Derâsûl; then south-east to a point in 34° N. lat., 47° E. long., and thence east to the frontiers of 'Oman, forms its northern boundaries. Its eastern boundaries are 'Oman, and its southern the range as far as the Wâdi-Dowarâ, which they follow south-east to the boundary of the Wâdi-Rachie. The territo-

\[\text{source: } \text{Decennales et Observationes sur le cours du Bahr-el-Ahâj et sur quelques sources pontos de l'Arabie.}\]
was the peninsular tract round Mount Sinai, separated from the eastern part of Arabia Petraea by the Sinus Atlantides, now Bah Arab. The name of Arabia Petraea is not very antient, and even that of the town Petra seems to have been unknown before the time of Alexander the Great; the country however is so distant from the Eastern natures as being connected with the history of the Jews. Ismael, the chief of the tribe of the Ishmaelites, and the supposed ancestor of the Arabs, had his abode in Arabia Petraea. (Geness xxvi. 18.) Other tribes mention the name of the country in the same region, as Amalekite, Amaelekite, Hagaren, and Edomites or Edomaei, who inhabited the tract bordering on Judaea, which was called Idumea. In the time of the Romans, the Nabathaean or Nabataeian were the ruling nation in Arabia Petraea, and are found on inscriptions of Nabathaei, and are consequently the same tribe as the Ishmaelites of the Scriptures. In the time of Augustus the Nabathaean possessed the northern part of Arabia Felix also. The name of Arabia Petraea is not mentioned by Strabo, who calls the country 'speciea novi Naboraria,' the Nabataean Arabia. Trajan conquered this country, and united it to Palestine; it was afterwards called Palastina Tertia, and thus Stephano Byztantius (Titre) says that the term of Petra was situated in the 3rd Palatine (Petrar. P. C.) King Baldwin I. con-
erated part of the country, and caused its principal town, Kasa, to be called Mont Royal. The antient writers mention several towns in Arabia Petraea, among which Petra is first in importance, as it is the abode of those who live between the Dead Sea and the Gulf of Akaba, and it was also called Rokem. (Arab. P. C. and P. C. S.) Colliers, Noticia Orbis Antiqui, vol. ii. pp. 357-463.

AEROMETRE (from the Greek aerus, light or thin, and diemeter, a measure) is an instrument employed for the purpose of ascertaining the specific gravities of fluids, generally such as are less dense than water, but capable of being used also to determine those of any fluids, and even of solid bodies. It differs little from an hydrometer, and in its simplest state it was merely a glass ball, hollow, and having attached to it a graduated stem also of glass, a weight was applied beneath the ball in order that the instrument might float in a vertical position when partly immersed in a liquid; and the different depths to which it sank in different fluids were indications of the relative densities of the fluids, the volume of a cylindrical portion between any two graduations on the stem being some known part of the whole volume of the instrument.

But an instrument of this kind was soon found to be very defective; for when immersed in different fluids, the elevation of the fluid depressed by the weight of the instrument, and the difference of the elevation in different fluids, were unequal, and thus the difference between two immersed volumes could not be correctly estimated. Fahrenheit improved it by forming at the top of the stem a small cup, receiving weights, by which, when the instrument was placed in the fluid, the fluid displaced by the weight would stand on the level of the fluid surface; the weight of the instrument itself, with that of the objects in the cup, were together, of course, equal to the weight of the fluid displaced by the immersed part; and the difference between the weights in the cup, when the mark was successively at the surfaces of two different fluids, allowed a nearly correct estimate to be made of the difference between the specific gravities of the fluids.

We have since been made in the construction of the instrument; and the best form is probably that which was given to it by Nicholson, and which bears his name. It consists of a hollow cylinder, or sphere, of copper, from each extremity of which proceeds a stem; that which, when the instrument is in a vertical position, is uppermost is a wire of hardened steel about 1/4-inch in diameter, and, like Fahrenheit's instrument, it carries at its top a small cup in which weights may be placed; to the lower stem, which is short, is attached a small vessel containing a solid body whose specific gravity it may be required to determine. The instrument is so adjusted that, if a weight equal to 1000 grains be placed in the upper vessel, the whole will sink to the bottom of the vessel from the weights, and of the specific gravity of Fahrenheit's thermometer, a mark made on the stem is on a level with the fluid surface. When the specific gravity of a fluid lighter than water is to be determined, the instrument is plunged into the fluid and weights are placed in the upper vessel till the mark on the stem is at the surface; then, if w in grains, be the weight of the instrument when unloaded, and w the weight placed in the cup as just said: also if s be the specific gravity of distilled water, and s' that of the fluid in which the instrument is placed, we have, by hydrostatics, 

\[ w + 1000 = w' + w' + w + w' + w'; \]

whence s' may be found.

To obtain the specific gravity of a solid which does not imbibe water: after placing the instrument in distilled water to find the weight of the body, and weights, in grains added to the mark on the stem at the level of the surface, these weights being subtracted from 1000 grains, leave the weight of the body in air: then placing the body in the upper vessel, let other weights be added in the upper vessel till the mark on the stem is at the level of the surface; these additional weights will express the loss which the body sustains by being immersed in water. Consequently if w' be the weight of the body in air, w' the loss just mentioned, s the specific gravity of the water, and s' that of the body, we have by hydrostatics,

\[ w' + s = w' + s'; \]

whence s' may be found.

If the substance whose specific gravity is required be, like wood, capable of imbiping water during the experiment, it should be left in the lower vessel, while under water, till the instrument is stationary, when the additional weights in the upper vessel will express the weight of the displaced water, and the weights in the lower vessel, placing the instrument in the dried surface, let the substance be placed in the upper vessel and weighted in air as at first: the difference between this weight and that which was found before the substance was put in the water is the weight of the water imbibe; and this must of course be subtracted from the total weight of the substance in water, previously to substituting the values of the terms in the proportion. The theory of the araeometer and hydrometer is given in Gregory's 'Mechanics,' vol. i. art. 406. 350.

For fluids of greater specific gravity than water, such as the concentrated acids, an instrument of the like kind which was invented by Guyton de Morveau, and is designated 'Gravimeter,' may be used. It is made of glass, with an upper and lower cup, in the former of which may be placed a constant weight, and in the lower a glass ball containing mercury. The weight of this body in air is made exactly equal to the constant weight together with the weight of a body of distilled water equal in volume to the ball containing the mercury. It is evident therefore that in the water this last object will be exactly equivalent to the constant weight, supposing the latter to be placed in the upper vessel; so that, in use, its weight is expressed by the number of grains in the constant part; and at the same time the position of the instrument being plunged in a fluid more dense than water, a weight to be placed in the upper vessel much greater than that which could be otherwise introduced consistently with the preservation of the vertical equilibrium.

Now the constant weight being that which, in distilled water at the standard temperature, sinks the instrument till the mark on its stem is at the level of the surface; the weight of the instrument without the ball of mercury, together with the constant weight, is the weight of a volume of the water equal to that of the immersed part including the ball; and when the instrument is introduced in a heavier fluid, its weight together with the constant weight and as many grains as will depress the mark on the stem till the surface, will be the weight of an equal volume of that fluid. Consequently, if s be the specific gravity of the water is to the required specific gravity of the fluid; which last is thus found.

ARANJAA, in F. C., is a misprint for Aramea. (Aramea, P. C.)

ARACARITRES (Prel), a genus of fossil plants found in the liles of Lyme Regis.

ARAXES. [Ars, P. C.]

ARCADE. In addition to its proper technical meaning, the term has of late years received different signification among the Parians more properly designate a passage or gallery, viz. an alley lined on each side with shops, and roofed over so as to be in fact a sort of covered street, extending from the westerly, and of uniform design throughout in its architecture. So far, an arcade answers to the idea of a bazaar, the chief distinction between the two being that the latter has not so much of street character about it, but consists either of a single spacious hall or separate rooms, fitted up with counters &c., stands,
and may therefore be likened to a single large shop occupied by a number of different dealers, whereas in an arcade the shops are quite distinct from each other, and enclosed in front with windows after the usual manner; and they have besides dwelling accommodation, kitchen, &c. beneath, and a chamber or garret above. Thus, in every way, there is but one entrance to each.

Another distinction is that an arcade serves as a public thoroughfare for foot-passengers. As to such a place being a very great public convenience there can be but one opinion,—as in dirty or wet weather, when the advantages attending such houses, and the satisfaction they give to themselves, are very evident, and no pretence of elegance or even of decency has anything in accordance with the title bestowed on it, it being neither arcaded in any way nor arched over. The Lower Arcade in the Strand (erected 1831) manifests very great improvement upon that first specimen, for it is really a very handsome and tasteful piece of architecture; the side elevations are divided by pilasters into compartments, each of which contains a shop-front, with an ornamented triple window over it, and above that a semicircular one in the arches of the Pantheon; and an arcade can, each of its divisions is covered by a pendentive dome with a circular skylight; and these numerous domes and their arches produce a singularly pleasing perspective effect. The same may be said of the Royal Arcade at Newcastle, erected a few years later, in which, as to the side entrances, the same device of alterations—and those not for the better in the side compartments—yet where, while so little has been done, there is such ample scope for variety, this mere repetition might have been avoided. Another point of merit is that all the arches do not agree with us in an example of something decided and marked by one striking peculiarity in regard to its plan: the Victoria Arcade at Ryde in the Isle of Wight, completed in 1836, after the designs of Mr. W. T. Davidson, consists of two compartments, each of which has in the centre of it a high circular dome covered with a flat-topped dome with a single row of large panels, but the avenues are not arched. Although in point of architecture this example is exceedingly plain, the general combination is highly effective and pleasing, and also suggestive of many other ideas. The central avenue of Covent Garden Market also affords an example of what, though not so called, may be classed as an arcade, inasmuch as it is a covered street of shops; and it is referred to as exhibiting a very different character from the preceding ones, the prospect towards which is less deformity, yet producing much architectural expression in its upper part on account of its open timber roof, and the 'clerestory' formed by openings which are left unplastered in the upper part of each side; consequently the light is admitted, yet vertically, and in a manner that produces the effect of something different from that attending lanterns or skylights.

In regard to degree of architectural adornment this example ought to be placed first, as being of far more primitive character than the others, and also the least attention to ornament of any kind. In the new Exeter Change, on the contrary (erected 1848-9, by Mr. Sydney Smirke), decoration of quite a novel kind, for this country at least, is introduced, there being no previous application of it, in any such place. The Pantheon is a Peacock. Here you have, as it were, prominently, a polychrome embellishment, which is there applied both on the upper part of the walls (in ornaments and pannels between the windows over the shops) and on the cove of the ceiling. The plafond of the latter may be said to be open, it being merely glazed so as to form a continuous skylight over the avenue, which circumstance constitutes a strong point of difference between this and all the preceding examples. No less difference is there in several other respects; the windows are the apparatus of a place of thoroughfare and business. Besides that it is of short proportions, the length being only about five times the width, it is more enclosed, therefore has more of in-door character, for instead of being open at the ends, or entered immediately, as it is in the other, it is entered by a very small number of them polygonal in plan, yet not exactly alike, the one being a hexagon, the other a heptagon, which are ingeniously adopted in order to obviate the difficulty of size, viz. the oblique position of the 'passage' between the two streets which it connects. It is perhaps to such difficulty alone that we are indebted for a novelty of plan and ensemble, that without it would not have been sought for. Those vestiges greatly enhance the effect of the avenue itself, inasmuch as they render it by contrast lofter than it would otherwise appear. It should be added also that the Pantheon near Belgrave Square is a 'passage' of the kind, which although of plain is of pleasing character, and has a peculiar air of spaciousness and cheerfulness. Among the Parisian arcades, the Passage Colbert is one of the most striking, for its extent and architectural display, towards which last its Rotunda contributes in no small degree.

ARCA'DIUS CHARIUS, AURELIUS. [CHARIUS, P. C. S.]

ARCADE COURT OF. At the time when the former article under this head was written (P. C.), it was expected that the Court of Arches would have been affected by a general measure for the reform of the ecclesiastical courts; but the attempts which have been made to accomplish this object have not hitherto been successful, and more than one bill for consolidating the jurisdiction and improving the practices of these courts has been abandoned. In the session of 1844 a bill was brought into the House of Commons 'For facilitating the proceedings of the Court of Arches,' and it was expected it would tend to the saving of expense, and to the better administration of justice, if either litigant party in any contested suit in any ecclesiastical court, either in the province of Canterbury or in the province of York, had the right to remove their cause gratis to the latter court, and to avoid the payment of a fee to the former. The bill was brought forward in the House of Lords relating to the ecclesiastical courts generally, which, among other things, provides that in these courts the fees arising from the exercise of jurisdiction, of the Prerogative Court of Canterbury, by transferring the jurisdiction of the latter court to the Court of Arches; but this bill was not carried. By 3 & 4 Vict. c. 65, the dean of Arches is empowered to sit as assistant to or in place of the dean of Canterbury, when vacated, or when by reason of his being a prince or of possessing the office of archbishop of Canterbury, he is debarred from sitting in that court. Advocates admitted in the Arches Court of Canterbury are admitted to be advocates of the High Court of Admiralty of England.

A Parliamentary Paper (No. 397) printed during the session of 1844 contains some information respecting the practice of the Court of Arches. There are no bye-laws, regulations, or resolutions made by proctors of the Arches or Prerogative Courts of Canterbury relating to the articling of clerks to proctors, or to the admission of proctors. The articling of clerks and admission of proctors are regulated by a statute of the archbishop of Canterbury, bearing date the 50th of June, 1896. By this statute, the number of proctors of the Arches or Prerogative Courts does not exceed sixty; forty, it was, among other things, ordained that there should be no less than forty in the Arches Court, each of whom should have power and privilege to take clerks apprentices, and that the remaining proctors should be esteemed and called supernumeraries, who should not have the right to take more than one clerk apprentice at a time. And there is added, that no proctor having one such clerk should be capable of taking another at the same time, until the first should have served five years. It is in practice required that a proctor shall have been five years on the list of the thirty-four seniors before he becomes more than a proctor, and he is to have the above rule with respect to age has, under particular circumstances, been occasionally dispensed with by the judge. The date and authority for these two rules are not known. The court has been seated, or has sat, by virtue of a writ of prorogation to a judge of the Prerogative Court, mentioned in the statute as made in 1896, do not appear to have been registered. It is conceived that they must have been rules and regulations to be observed in the conduct of suits, and not to the articling of clerks on masters. The Office of Archdeacon of Canterbury is that of the official principal of the Arches Court, or his surrogate, and are registered in the Arches Court. According to the present rules, a candidate for admission as an advocate is required to deliver into the office of the vicar-general of the province.
of Canterbury a certificate of his having taken the degree of Doctor of Civil Law, signed by the registrar of the university in which he belongs. A petition, praying that in consideration of such qualification, and of the services he has rendered, he may have access to the records of the university, is then presented to the archbishop, who issues his fiat for the admission of the applicant, directed to his vicar-general, who thereupon causes a rescript or commission to be prepared. In 1599, when the archbishop of Canterbury, empowered and requiring him to admit the candidate an advocate of that court. This commission contains a proviso that the person to be admitted shall not practise for one whole year from the date of his admission. The rescript of the archbishop, the records of the Archers Court; the rescript of the archbishop being first read, and the oaths of allegiance and supremacy, with two other oaths, taken. This admission in the Archers Court is the first for being any of the other ecclesiastical courts of Doctors' Commons.

The number of advocates is twenty-four.

The Court of the province of York which corresponds to the Court of Archers is called the Chancery Court of York. The number of advocates practising in this court has never exceeded four. They are admitted by fiat of the archbishop, directed to his chancellor, and have power to practise in all the courts of the archbishop; but it is not necessary that they should be Doctors of Civil Law. (Parliamentary Paper, 287, 235, 1844.)

ARCHIMEDEAN SCREW. [SCREW PROFESSORS, P. C. S.]

ARCHIGRAPH. [CLOGHRAF, P. C. S.]

ARD, LOCH, is a lake in Scotland, in the county of Perth, and in the parish of Aberfoyle: it lies south of Loch Katrine, or Katrine, from which it is separated by huge mountain masses, the summit of which, known as Ben Veen, rises to more than 3000 feet above the sea. On the west the lake is enclosed by high mountains. Ben Lomond, which rises 3197 feet above the sea, is only about four miles distant. Between the two mountain-masses lies Loch Chon, where the river Forth originates. It runs in a narrow valley to Loch Ard, and from thence to Loch Katrine by a channel about half a mile wide. To the south and east of the lake are hills, descending towards its shores with a moderately gentle slope. Where the river leaves the lake there is a small cataract, below which it runs through a narrow valley, called the Laggan, to a more level country.

(Sinclair, Statistical Account of Scotland.)

ARDWICK LIMESTONE, a calcareous bed or series of beds containing shells and fish remains, in the upper part of the Silex of Manchester and Leebmouth. There is a coal-bed above it at Manchester.

ARETINO, SPINELLO, one of the most distinguished of the early Italian painters, was born at Arezzo in 1316. He derived his surname from his birthplace, Arezzo. He was one of the most celebrated painters of his time. His father, Luca Spinelli, was a Florentine, who settled at Arezzo when the Gibellines were expelled from Florence. Aretino was the pupil of Jacopo del Casentino, whom however he surpassed even as a boy. He obtained a reputation very early by some frescoes illustrating the life of San Niccolò, which he executed in a new church of that saint, built at Arezzo by Dardano Aciacutti, expressly for the occasion of a council to be held there by Pope Eugene IV.

This church was destroyed by fire in the time of Vasari, and Arezzo, however which Aretino painted in it procured an invitation from Baroni Capelli, a citizen of Florence, to paint the principal chapel of Santa Maria Maggiore, with subjects from the life of the Virgin, and of Saint Antonio Abate, his father's patron. His first work in this style was the fresco of San Antonio Abate and the Virgin, in the church of the same name in the monastery of Santa Maria della Pieta, in Arezzo, which still remains; others in the monastery of San Bernardo, near Arezzo; and others in derelict, in the monastery of Monte Oliveto near Florence. His next work was the frescoes illustrating the life of San Barnieri, in the Campo Santo of Pisa, where Vasari reckons among his best works; scarcely anything of them now remains, but there are prints of them in Lasinio's 'Pitture a Fresco del Campo Santo di Pisa.' These frescoes, which were dedicated to the bishop, are represented in a series of three, the picture of the Madonna and infant Christ by Spinelli; it was in the old Duomo, or cathedral, and when that church was pulled down, the fresco was cut out of the wall, and placed in a small chapel, which was built in the old church of the Madonna del Duomo, taking the name of the picture.

The principal works of Spinelli are not mentioned by Vasari; they are in the town hall of Siena, and are from the P. C. S., No. 18.
efforts to promote a taste for such studies among his country-
men. He was one of the most active and influential members of
the Academia de Letras Humanas at Seville, which institu-
tion played a part in the development of posterity. He moved
in each of the five provinces of Spain, sent members of the
jewelled order of the Grand Cross of the Order of the To
delo of the Star, and was a favorite of the Regent Duke of Orlan
des, and had apartments in the palace of St. Cloud. He came to
England in 1721, with letters of introduction to the Prince of Wales,
afterwards George II., and returned in 1756 to his own coun-
try with a fortune of 800,000 francs; he died at Geneva, in 1769.

Featherstonhaugh, Whistle, in an Address, 1748, to the Representa-
tives of the State, in which he laid before them the state of their
affairs, and the various curiosities to the library of that place. Part of
his bequest was some pieces of a drawing of a Ledo, which is
made in Paris, said to have been copied from a basso-relievo by
Michelangelo. It appears to have been a wonderful perform-
ance, and it is supposed to have been originally executed in the
style of Raphael, but destroyed in 1784, and cut up into fragments,
distributed in various directions. Arlau'd was originally exclu-
sively for the church; he was a man of general acquirements, and
was well versed in languages. While in this country he
accomplished a manuscript in Latin, and finished it with Sim's
help, after his retirement to Geneva. Among the mini-
atures which he painted in London was one of the celebrated
duke of Marlborough. He painted also one of the Prin-
cess's, upon which Count Hamilton wrote a poem, which
was in the fourth volume of his works. There is an
ote on Arlau'd's Ledo in the third volume of the Writs
of M. de Bar, Amsterdam, 1759.

brosen; Walpole, Anecdotes of Painting in England.)

ARMAGH OBSERVATORY. The Observatory of
Armagh was endowed and founded in 1791 by Archbishop
Robertson, the greatest bachelor and improver of that ci-
ty. It was a gift of the revenues of the diocese, and was
entirely carried on by his immediate successor, till the present
primate, Lord John George Bereford, completed and surpassed the original design.

It stands north-east of the town, on an eminence of compact
cliff, raised above 100 feet above the surrounding land, with
substantive rock is mountain limestone. At the north
west, the ground rises about 89', at a great distance; but to the
south at six miles a hill has 238' altitude.

From the centre of the dwelling-house a tower rises 60 feet, with
which the whole town is visible, the building being placed, under
a revolving dome 16 feet in diameter, on an insulated pil-
lar. This, which for many years was the only available instru-
ment, was conceived, by its illustrious maker, to be capable
of supplying the place of a transit and a meridian circle. It
was, for this cause of mistakes, taken to the public, but it will appear, by a refer-
cence to Mr. Pond's description of the Westbury circle (see results of its observations are given), that it was not inferior to
any instrument then existing. Its hour-circle of 50 inch
circles, 3 feet diameter, divided into 360 parts, the declination-circle, 50 inch
circles, 5 feet diameter, divided into 360 parts, the equatorial portion of 50 inch
circles, 21 feet diameter, divided into 360 parts, the polar circle, 30 inch
circles, 10 feet diameter, divided into 360 parts, the polar circle, 20 inch
circles, 9 feet diameter, divided into 360 parts, the polar circle, 10 inch
circles, 5 feet diameter, divided into 360 parts, the polar circle, 5 inch
circles, 3 feet diameter, divided into 360 parts, the polar circle, 2 inch
circles, 2 feet diameter, divided into 360 parts, the polar circle, 1 inch

At the east of the house, but connected with it, are
1. A calculating-room, containing the observatory library,
2. The transit-room, 19 feet by 13, with an observing apar-
ature (or chase) of three, contains a transit instrument, by
Thomas Jones, of 68 inches focal length and 8 aperture.
This is constructed with the same precision as the other,
but is peculiar in the arrangement of its Ys, which have
bears, 5-inch ears, long, faced with quartz, and have not even
marked the pivots, after the constant use of 16 years. The
base or center of the instrument being removed, and the
painters are prevented from disturbing the meridian plane of the
instrument. Besides the usual circles at the eye end of the
telescope, it has one of 10 inches diameter on the axis, which
allows polar distance, and is now exclusively used. The
transit is by Earnshaw, and may be reckoned unique; as
the similar one, which was made for the late Mr. Larking,
is said to have disappeared. It is jewelled with singular
precision, and its cases made as nearly air-tight as possible.
The micrometers screwed into the box, are of-that cloth admits, to
which probably it is owing, that after 50 years its wheelwork
exhibits no trace of wear. It even works unaided through
its valve. It moving weight is 3 lbs., and its original telescopic
size is a griffon weighing 21 lb., but it was not constructed
compensated for temperature, this was changed for a mercarial

ARMIN, ROBERT, a favourite comic actor and small part author, was a son of William and Sarah Grubb, and was presented to the Primacy by her Majesty, along with several other of its instruments. It turns freely in an insulated cast-iron framing, for the purpose of revolution, and is in perfect steadiness. One of the best works by this class; the injudicious combination of wood and brass in its structure, does not keep its adjustments: this defect however is about to be remedied. The telescope has 44 inches aperture; the cross 6' on each side of the sextant, and 12 feet radius of curvature, by done. In the main tower, under a sliding roof, is also placed a journeyman time-piece, and a triple 34 feet achromatic provided with wire, and divided object-glass micrometers.

4. The circle-room, 15 feet 13, has a mural circle by Thomas Jones, 68 inches diameter, and bearing a telescope similar to the transit. It is divided on the face next the pier, on an alloy of gold, and is read by twelve achromatic microscopes, so large that the observer's eye is 35 inches from the object-glass bearing, in a such manner, that it can be changed with temperature. The illumination of them, as well as of the clock (by Earnshaw), and of the spider lines in the telescope, is effected by a single light placed in the centre of a circular frame bearing reflectors; and the movements of the instrument are taken up by a spider consisting of 35 threads, very similar to the standard one of the Royal Society; and the external thermometer, and other meteorological instruments, are at a northern window in the passage to the eastern dome.

5. This, also of 15 feet diameter, contains a large reflector equatorially mounted by Mr. Grubb of Dublin. It is 16 inches aperture and 115 feet focal length. It is Cassegrainian, with the higher powers; but for sweeping and observing assumes the Newtonian form is preferred, as giving a wider field. It is mounted on large 10 feet Newtonian, made specially by Sir W. Herschel for George III., and one of 2 feet focal length and 6 inches aperture by Short, in excellent preservation, which can be used in any of the three forms. These are, when employed, moved to any desired point by a strong-ovoboat, and the movements of the circle are regulated with the speed of the observations, and to the standard one of the Royal Society; and the external thermometer, and other meteorological instruments, are at a northern window in the passage to the eastern dome.

6. This also of 15 feet diameter, contains a large reflector equatorially mounted by Mr. Grubb of Dublin. It is 16 inches aperture and 115 feet focal length. It is Cassegrainian, with the higher powers; but for sweeping and observing assumes the Newtonian form is preferred, as giving a wider field. It is mounted on large 10 feet Newtonian, made specially by Sir W. Herschel for George III., and one of 2 feet focal length and 6 inches aperture by Short, in excellent preservation, which can be used in any of the three forms. These are, when employed, moved to any desired point by a strong-ovoboat, and the movements of the circle are regulated with the speed of the observations, and to the standard one of the Royal Society; and the external thermometer, and other meteorological instruments, are at a northern window in the passage to the eastern dome.
In this occupation he spent the last fourteen years of his life; and during that period, though so diligently engaged in his studies, and with so many important public duties, he still found time for two great public events and political questions of the time. He was one of the most decided opponents of the Oxford new school of theology. His idea of a Christian church was first given in his pamphlet on Church Reform, which he was induced to publish in 1837, in which he forcefully and clearly expressed his sentiments on the subject. These sentiments were afterwards embodied in his Fragment on the Church recently published; in which he hits the key-stone of the Tractarian heresy, in attacking what he considers to be their false notions of the Christian priesthood.

In 1836 the office of a Fellow of the Senate of the new London University was offered to him, on the retirement of Dr. Spring Rice, the Chancellor of the Exchequer, and the office was accepted. Dr. Arnold at first consented to join the University 'without insisting on a Scriptural examination, on the alleged ground of fact, that such an examination is not practicable on account of the objections of different classes of Christians, and on the hope, which he distinctly expressed, that the Christian character of the University might be secured without it.' But he subsequently became convinced that the examination of the School was of such importance that he did not think it unjust or indisputable, and he gave notice of his intention of recommending the introduction of the Scriptures as a part of the classical examination for every degree. In December, 1837, his success was assured; Dr. Arnold's proposal was adopted by the Senate, and the examination either in one of the Four Gospels or the Acts of the Apostles in the original Greek, and also in Scripture History. In consequence of the remonstrances from various bodies of Dissenters and from the Council of University College, London, and partly in consequence of the strong representation of the Secretary of State (Lord John Russell), through whom an appeal had been made by the remonstrants to the law officers of the Crown, a larger meeting of the Senate of the University was summoned by the Vice-Chancellor in 1838, in which the former motion was overruled, and in its place it was resolved, 'that examination in the Hebrew text of the Old Testament, and in the Greek text of the New, and on Scripture History, shall be instituted in this University; and that all candidates for degrees in arts may, if they think proper, undergo such examination.' The Senate immediately proceeded to institute a voluntary examination, with prizes, in the texts of the Old and New Testaments and in Scripture History. Dr. Arnold was brought before the Senate of the London University, in November, 1838, being led, 'after the fullest consideration and inquiry, to the conclusion that the voluntary examination would not be satisfactory,' and 'at the request of Borough (Dr. Arnold, li. p. 126), or, as he expresses himself in another passage of the same letter, would not satisfy, either practically or in theory, those principles which appeared to him indispensable.'

The history of this transaction is given at length in Stanley's 'Life of Arnold' (ii. p. 10, &c.), and Dr. Arnold's views and opinions appear from various letters in the same volume (pp. 13, 83, 91, 94, 107, 126). The history of the London University is given in P. C. [University of London], and the various documents relating to examination on religious subjects in that university are contained in the Parliamentary Papers (No. 586) relative to the University of London, printed by order of the House of Commons in 1840 (pp. 25, 27).

Dr. Arnold's mind was early directed to the social condition of the working classes of this country; and many efforts were made, and a variety of plans devised by him, not only for improving it, but for directing the attention of the public to a subject of so much importance. With this purpose he gave lectures at the Rugby Mechanics' Institute, started a new paper in 1831 expressly for the use of the lower orders, and in the same year, and also in 1832, wrote letters in the 'Sheffield Courant,' and subsequently in the 'Herts Reformer,' for the purpose of introducing a moral element into the measures intended for the social benefit of the masses; and although much of the franchise would be useless, if not pernicious.

The Whigs, to whose party he was more nearly assimilated in opinion than to that of the other, offered him a position which he did not accept. The year before his death, however, he was appointed by Lord Melbourne to the regius-professorship.
of modern history at Oxford—an appointment which gave him the opportunity of devoting his time to only his introductory course of lectures. At the very summit of his reputation as a teacher, and at the time when the editor, for which the liberality of his religious and political opinions, his name had been held by men of his own pro-

fession, the dignity of a major, or in any case, an ex-

ceived was every day becoming more manifest and more distinctly understood, he was seized with a fatal disease, which carried him off in a few hours. He died on the 12th of June, 1842, and the 58th section has another retrospective effect, empowering all persons in execution at any time of the act on any judgment in any action of debt, wherein the debt, exclusive of the costs, did not exceed the sum of 20l., to apply to a judge to be forthwith discharged out of custody; the judgment however is still to remain as a personal or the discharge of the debtor, and the creditors may have their remedy by execution against his property and effects.

Pleaders' ed. note 23.

ARREST OF JUDGMENT.

ARREST OF JUDGMENT. When an action at law has been carried through all the stages previous to the judg-
ment, unless the defendant has obtained a new trial or verdict, he may be had in execution for the judgment; but if the defendant may still move in arrest of judgment: that is, he may pray the court to withhold or arrest the judgment from the plaintiff, on the ground that there is some error appearing on the face of the record, which vitiates the judgment or proceedings. In no case can the arrest of judgment be granted on the ground that the record may arise, from the commencement of the suit to this period, the court is bound to arrest the judgment. The form must be such as is apparent on the record; and generally speaking, it is not an error in a mere point of form. This was formerly otherwise; but certain statutes have been passed at different periods, called the statutes of jealously and amendments, by the effect of which judgments at the present day cannot be arrested, unless for any merely formal objection. The statutes of this kind are 14 Ed. III. c. 6; 9 Hen. V. c. 4; 4 Hen. VI. c. 3; 8 Hen. VI. c. 12, 16; 22 Hen. VIII. c. 50; 18 Eliz. c. 14; 21 Jac. I. c. 13; 16 & 17 Car. II. c. 6; 4 & 5 Ann. c. 16; 9 & 10 Geo. c. 20; 5 & 6 Geo. I. c. 19. For further information on this matter, see Blackstone's Comm. iii. ch. 24; Stephen On Pleading; Commen's Dig., tit. 'Pleading,' § 48.)

ARRESTMENT in the law of Scotland is a process by which a creditor may attach money or moveable property which a third party holds for behoof of his debtor. It bears a general resemblance to foreign attachment by the custom of London. [ATTACHMENT, FOREIGN, P.C., p. 56.] The person who is at

searched or arrested is called the arrestee, and the debtor is called the common debtor. It is of two kinds, arrestment in execution and arrestment in security. The former can proceed only on the decree of a court, on a deed which contains a clause of registration for execution, or on one of those documents, such as bills of exchange and promissory notes, which by the practice of Scotland are placed in the same position as deeds having a clause of registration. Arrestment in security is generally an incidental procedure in an action for the constitution of a debt; but it may be obtained from the Bill Chamber of the Court of Session on cause shown, as a method of constituting a security for a debt not yet due. This latter class of arrestments is under the equitable control of the judge who issues it; and it is a general principle that it cannot be obtained unless the claimant show that circumstances have occurred which have a tendency to make his chance of payment less than it was at the time when he entered into the engagement with his debtor. An arrestment may be recalled on it being proved that it should not have been issued, and an arrestment in security may be 'loosed' on the debtor finding security for the pay-

ment of his debt. An arrestment in execution expires on the lapse of three years from the date of the judgment or arrestment in security, on the lapse of three years from the day when the debt becomes due. In the meantime, the person in whose hands the process is used, is liable in damages if he part with the property arrested, but it cannot be attacked after he has parted with it, or handed it to a surety for the debt. The arrestment is made effectual for the payment of the debt by an action of Forcibige, in which the common debtor is cited. It concludes for payment of the money if the arrestment be made on money, or for their sale for behoof of £.
ART

EDITOR, if it be laid on other moveable goods. The arrestee may plead against the arrestor whatever defence he might have. His common defence was that the order of the local courts was enlarged in regard to arrestments, and the process was generally regulated, by the 1 & 2 Vict. c. 114. The practice on this subject will be found in Darling's 'History of the Chancery.' At a later period a sort of assize of the annual subscription-list, which takes place early in the spring, the Committee of management set apart a portion of the aggregate sum for the purpose of engraving and printing the various objects laid open to the subscribers. It was a copy of a word list for each guinea subscribed. By the combination of a very great number of persons to subscribe for this one work of art, and the avoidance of risk, incidental expenses, and publisher's profits, this print, though at least equal to what would have been a larger guesswork in the way of subscriptions, was allotted to the subscribers at so small a cost as to leave by far the greater part of the sum subscribed, as a fund applicable to the purchase of pictures, sculpture, and other works of art. This plan was adopted in the national subscription, in which the 3d prize, ranging from 10l. to 400l., and on the day appointed for the annual meeting of the society these prizes are distributed among the subscribers by a process resembling the drawing of a lottery, which gives an equal chance for every guinea subscribed. The prizewinners are allowed to select works of art to the value of their respective prizes from any of the five annual exhibitions of works of art in the metropolis, for the current year, which works, when selected by the prizewinners, are purchased and paid for by the committee, which, therefore, has not only an eye on the purchase of pictures, sculptures together, and exhibit them gratuitously for some weeks, first to the subscribers and their friends, and afterwards to the public. When the selected works fall short of the amount of the prize, the difference is paid out of the fund to the Reserved Fund of the association, and when they exceed it, the difference is paid by the prizewinner.

A PORTION of the funds is also applied to the offering of premiums for original designs, and the production of bronzes and medals. The amount of subscriptions in the second year, which was on 21st of January, 1837, was 489l. 6s., but it has increased so rapidly that the last report, that for 1844, shows a subscription of 14,843l. 1s., of which 8850l. was set apart for the purchase of works of art, being divided into 256 prizes of various amounts, in the proportions which every supporter understands from the outline illustrations of the 'Pilgrim's Progress,' the result of premiums offered by the society, and will also, on its completion, receive an impression of a line engraving by a first-rate artist from a landscape by Stanfield. The annual exhibition of prizes, or selected pictures, affords another important means of fostering a national love of art; that of the year 1843 was open for four weeks, during which it was visited by nearly 200,000 persons.

The committee of the Art-Union of London' has given rise to many similar associations, one of which has for its object the promotion of the fine arts in Ireland. In this, and some others, the works of art are selected by the committee themselves, and a subscription of 1l. 6d. for each of the Committee of the Art-Union properly so called, has also brought into existence several lotteries for the disposal of works of art, in which, notwithstanding the adoption of a similar course of proceeding, the principle is essentially different, such being considered by many persons as mere revivals of a species of dissipation which has long been illegal in this country: and, notwithstanding the opinions of some eminent counsel in favour of the legality of Art-Unions, the difficulty of dissociating them from lotteries unquestionably illegal, led government to issue a notice in April, 1844, which had the effect of suspending their operations for some months. A parliamentary committee was subsequently appointed to inquire into the subject, with a view to placing them on a basis of law and regulations, and some slight encouragement to the improvement and diffusion of art through the different classes of the community; but, as the investigations of this Committee could not be brought to a close in time for introducing a bill for their regulation in the session of 1844, a short act was passed by the legislature against such penalties as they might be considered subject to, for one year, so as to allow their proceedings to be immediately resumed, and the money then in hand to be expended for the purchase of pictures. This act expired by the standing that early in the present session (1846) a bill will be introduced to carry out the objects for which the Committee was appointed.

ART

A R T

AWESERI S A B S I N T H I U M (Woadroot). Medicinal Actions and Uses. This indigenous perennial herb is found wild on waste places, but which is required for medical use is mostly cultivated. The upper part of the stem, with the

who choose to subscribe two, three, four, or five times that amount being considered to have a proportionate number of votes. One member of the Select Committee is 'to inquire into the best means of extending a knowledge of the arts, and of the principles on which they are founded, to the people of the turing population of the country,' and 'to inquire into the constitution, management, and effects of Institutions connected with the arts,' it is observed that among exhibitions connected with the arts, that then, and which had been called to the Institutions established in Germany under the name of 'Kunst Vereine,' and which were even then introduced into this country. These associations, for the purchase of pictures to be distributed by lot, observe the Committee, 'form one of the many instances in the present age of the advantages of combination. The smallness of the contribution required brings together a large mass of subscribers, many of whom without such a system of association would never have been patrons of the arts.' The Committee further remark that the German Waagen and Von Kleben, two of the witnesses examined by them, highly estimated the advantages conferred on the arts by such associations, which, according to Waagen, were introduced into Prussia about the year 1760, and thanks the patronage of the king and his minister Von Humboldt.

Down to the time at which this Report was published, such associations had made comparatively little progress in this country; but shortly after its appearance a number of gentlemen, among whom were Mr. Ewart, the chairman of the Select Committee referred to, and four other members of parliament, established a society under the name of 'The Art-Union of London,' which immediately obtained considera-ble advantage and which has since increased its number to a magnitude far greater than that of any kindred association. The professed objects of this institution are 'to aid in extending the love of the Arts of Design within the United Kingdom, and to give encouragement to Artists beyond that afforded by the patron-
irises, and unexpanded flowers, should be collected, for these pass possess the peculiar aroma, with a strong bitter taste; while the lower part of the stem is merely aromatic, and devoid of bitterness. (Golger.) It imparts its properties to wine peculiarly to a certain extent, and medicinal forms of it are—the watery infusion (boiled with cold water) and the extract: but the domestic preparations are numerous; these are made either by digesting it with alcohol, to form a disagreeable spirit, or by distilling it in small quantity while using any of the sweet wines, such as Tokay. This practice may have been derived from the ancients, most of whose wines were very rich and luscious; and in those times, when corrected for refraction and parallel, is equal to the angular elevation of the object above the true horizon of the place.

Artificial horizons of the kind just mentioned are generally used on land for the purpose of obtaining the altitude of a terrestrial object by means of the sextant, a circular disc, either held in the hands or supported on a small pillar; occasionally also, it is employed to obtain the angular elevation of a terrestrial object, as the top of a tower, a mountain, &c. The rays of light from the object, falling on the quicksilver, are reflected from thence to the eye of the observer; and, by the laws of refraction, the angles made with the reflecting surface by the incident and reflected rays are equal to one another; hence the reflected image of the object appears as much below the horizon, or surface of the quicksilver, as the object itself is above it; and on bringing, by the motion of the index of the sextant, the direct and reflected images to coincide, the angle read on the arc will, the eye being very near the quicksilver, be equal to twice the angle of elevation.

When the atmosphere is very clear, a glass roof may be used instead of quicksilver, but almost the least agitation of the air is sufficient to disturb the reflected image.

On a journey the conveyance of quicksilver is often inconvenient; and therefore scientific travellers have attempted to supply the place of an artificial horizon, as an artificial horizon, which through the frame of the mirror at equal distances from one another.

Since, with the usual reflecting instruments, double altitudes exceeding about 120 degrees cannot be observed, the artificial horizon just described would be useless, if the altitude of the object were greater than 60 degrees; but it may however be employed with instruments similar to those invented by Captain Fitzroy and Beechey, by which angles exceeding 180 degrees may be observed.

The artificial horizons permit very accurate observations to be made on land, but it is evident that they cannot be used at sea, even though well suspended in jibsails, on account of the unsteady motion of the ship; and some means of enabling a seaman to observe correctly the altitudes of celestial bodies is absolutely necessary, or but faint and even through the vapours near the horizon, is still a desideratum.

It is known however that when a conical or a cylindrical body terminating at the lower extremity in a point is caused to revolve rapidly on its axis, that axis soon takes, and for at least half an hour maintains, a vertical position; and efforts have been made to employ such a body, having a mirror on its upper surface, as an artificial horizon on board a ship. A 'Nautical Top,' as it was called, was proposed by a Mr. Serocold, in the Philos. Trans. 1760; but, on being tried at sea, its irregularity was found to be great, and the contrivance was abandoned. The late Mr. Troughton however, in 1818, made considerable improvements on the original construction, but his success was not such as to render the machine available. He made the top first cylindrical, but he afterwards gave it the form of a frustum of a cone; the reflecting plane formed the upper surface, and immediately under this was a stem terminating below in a steel cone, whose surface formed the reflecting plane of a steel cup. A rapid motion was communicated to the machine by the small wheels of, of which the first was turned by means of a handle on a ship.
the bubble of air: a line was traced on the horizon-glass, and a contact of the limb, or centre, of the celestial body was to be made with this; the instance. As a result, the latter aggregate to bound the reflected image of the bubble. The are passed over by the index would then express the altitude of the celestial body above the horizon. Instruments very similar to this have been executed by Mr. Robinson, and, for merely numerical purposes, their position of the altitudes obtained with them being within two or three of their true values.

ARTILLERY, APPLICATION OF. [TACTICS, P.C.]

ARTISIA. (Feet.) This name is equivalent to Stegaste, p.c.s. At present the opinion prevails that this is an internal portion of another plant, and not a pain-stem, as once conjectured. Coal formation.

ARTOYTTIES. [COMMISSION, P.C.]

ASAS. [NEW YORK.]

ASCLERIAS. [New York.]

ASCLEPIAS, a genus of plants, the type of the natural order Asclepiadeae. [ASCLEPIADACEAE, P.C.] Many of the species possess powerful medicinal qualities, and hence the name of the genus from Asclepius (Aesculus), the god of medicine. The genus is characterised by possessing a reflexed 5-parted corolla; a 5-leaved corona seated on the upper part of the tube of the calyx; the lacinias curved inwards, being in two or more rows, and the style terminated by a minute style. Pollen masses compressed, fixed by the taping tops, pendulous; the stigma depressed; the follicles smooth; the seeds coarse. Most of the species are native to America, herbaceous, with opposite, alternate, or verticillate leaves.

ASCLEPIAS, Syrian Swallow-wort, has simple stems with lanceolate oblong or oval leaves, gradually acute, and tomentose beneath; drooping umbels. Lamarck states that the Syrian Swallow-wort grows wild in Syria and Egypt. The latter species is the root of the true Ipecacuanha (Cephalis Ipecacuanha). The roots of A. prolifica are also emetic.

Asparagus, Bastard Ipecacuanha, has a simple stem, with oblong-lanceolate phylloclade leaves, tapering at both ends; umbels erect, solitary, lateral. It is a native of Curacao, Essequibo, Cumana, and Trinidad. Its roots are frequently sent to England as Ipecacuanha. The juice in the West Indies is reputed to be antihelminthic and styptic. The root is made into the principal ingredient to spin into intestines for wearing apparel; it is however more adapted for stuffing mattresses and pillows.

A. Curassavica, Bastard Ipecacuanha, has a simple stem, with oblong-lanceolate phylloclade leaves, tapering at both ends; umbels erect, solitary, lateral. It is a native of Curacao, Essequibo, Cumana, and Trinidad. Its roots are frequently sent to England as Ipecacuanha. The juice in the West Indies is reputed to be antihelminthic and styptic. The root is made into the principal ingredient to spin into intestines for wearing apparel; it is however more adapted for stuffing mattresses and pillows.

A. tuberosa, Tuberous Swallow-wort, has suberect stems, very hairy, and branched at top; scattered oblong-lanceolate, hairy leaves; umbels disposed in a terminal sub-corymb. It is native to North America, in stony places and sandy fields.

The roots are famed for diaphoretic properties, and in Virginia it is used for this purpose in inflammatory diseases, more particularly rheumatism. The roots of some authors is probably only a variety of this species, and has the same properties.

Many other species of this genus are used as medicines in the countries where they grow. The authors of A. stipitatus are composed of numerous small islands and pointed rocks, and has broken ground about it, so that it can only be approached with caution. A. Stipitatus is called the Group. The middle, or Peak's Group, consists of three islands of moderate size. The largest, Peak's Island, is four miles and a half long. The whole group occupies nine miles in length. The southern group is called Bally's Group. The islands are surrounded by a body of water. They rise from the water's edge with a steep ascent, but not to a great elevation. Between the mountain-masses are small valleys, almost every one of which contains a stream of water. The declivities of the mountains to the very top are clothed with large forest-trees, among which the Arecas olaraces and fan-palms are most conspicuous. The shores of the small bays, which are numerous, are lined with ledges and coral reefs. During the winter the wind is from the north and nor’easter, directed with much violence; in summer it blows from south and south-east, and the weather is fine, but even then the air is moist, and the islands at sunrise are involved in dense fogs. The animals are—vampires of a large size, herons, pelicans, swipes, rails, wood-pigeons, the common black crow, and some smaller birds. There are several kinds of fish, and sharks are very numerous; there are also crayfish and other shell-fish. Green turtles are so numerous as to cover nearly the flat sandy beaches of the small inlets: they weigh from twenty to forty pounds. Captains have seen two English sailors, who had grown pumpkins, water-melons, potatoes, sweet potatoes, and fricoli beans; they had also planted some coca-cut trees, and kept hogs and pigeons. It appears that these have been discovered by the Spaniards, but it is not known at what time. The wholesalers in the Pacific go from time to time there to take in water, and get a supply of fresh provisions by killing turtles. It does not appear that these islands have ever been regularly settled by any nation. On the western side of Peak's Island is a small but good harbour, called Lloyd's Harbour; it is surrounded by high hills, and is apparently the crater of an extinct volcano. On the eastern side of the same island is Fittow Bay, which is rather large, but open to the south-east, so as to be unsafe during the south-eastern winds, which prevail in summer.

Beechey, Narrative of a Voyage to the Pacific.

A'SAPPHIS (Brommiati), a very extensive genus of fossil Crustacea (Trilobites), most abundant in the lower Paleozoic strata of Michigan and New York. The Bemidji fossil beds of northern Michigan are prolific in this type, and with the Bemidji limestone form the Bemidji formation, one of the lower Silurian, as A. caudatus is frequent in the upper Silurian beds.

ASCARRIDIES. [ENTOZOIA. P.C.]

ASCLEPIAS, a genus of plants, the type of the natural order Asclepiadaceae. [ASCLEPIADACEAE, P.C.] Many of the species possess powerful medicinal qualities, and hence the name of the genus from Aesculus (Aesculus), the god of medicine. The genus is characterised by possessing a reflexed 5-parted corolla; a 5-leaved corona seated on the upper part of the tube of the calyx; the lobes of the calyx twisted inwards, being in two or more rows, and the style terminated by a minute style. Pollen masses compressed, fixed by the taping tops, pendulous; the stigma depressed; the follicles smooth; the seeds coarse. Most of the species are native to America, herbaceous, with opposite, alternate, or verticillate leaves.

A. Syrriaca, Syrian Swallow-wort, has simple stems with
The principal ingredient of the asphalting mastic termed Seydel Asphalte, is a dark brown bituminous limestone, found near the Jura Mountains. This stone is broken to powder and mixed with a portion of mineral tar, when intended for fine work, and with a greater portion when it is required to be resting upon a bed of pipes, as in the case of tanks, and application as cement; or, when intended for the coarser purposes of pavement and flooring, with mineral tar and sea-grit; and the whole is exposed for several hours to a strong fire, where the asphalting mastic and caldrons are provided for re-melting it upon the spot by fires of wood or coke. In this operation 1 lb. of mineral tar is first put into the caldron or boiler, to which, as soon as melted, 56 lbs. of powdered mastic, the pieces of not more than 1 lb. each, are added, the whole being stirred together with an iron instrument, formed something like a spoon with the centre of the bowl cut away, so as to reduce it to an oblong loop, and curved in such a way that the striker may pass the instrument close to the sides and bottom of the caldron, and lift the portions of mastic in contact with the surface, to prevent burning and ensure the perfect mixture of the ingredients. The caldron is then covered over, and a brisk fire kept up for a short time, to melt the asphalting mastic. In later processes it is added and stirred in. The caldron is again covered for a few minutes, and further quantities of tar and mastic are added, in the proportion of 1 lb. of the former to 113 lbs. of the latter, until the caldron is full, and the whole is completely melted and mixed. After the addition of the full quantity of the floor, jets of light smoke from the mastic, which will drop freely from the stirring instrument. It should be observed that for this purpose, as well as for the original mixing of the asphalting, note but mineral tar, resembling that with which the limestone is impregnated, should be used; and also that where the mastic needs to be very stiff, as for kitchen-floors, or for use in tropical climates, a less proportion of tar than the above should be used. In such cases also a larger quantity of grist must be added to the mastic, and the grist is added at this work as desired to convert fine mastic into coarse, it may be done by mixing, at the time of melting, 30 lbs. of fine clean grit to every 112 lbs. of mastic, increasing, at the same time, the proportion of tar from 1 lb. to 24 lb. for every 12 lbs. of mastic. When ready for use, the mastic mastic may be carried very quickly to the spot where it is to be applied, either in iron ladles, or, if it be necessary to remove it to a greater distance, in heated iron buckets. In all cases however it is desirable to keep them in a vault or basement, or, if covering brick arches or arch roofs, it may be hoisted to the top of the building, care being taken, whenever it is necessary to set it upon an asphalting part, to lay a few inches thick, and to lay the first row of bricks to support it, and to shelter the finished work from injury.

The method of laying foot and carriage pavements in asphalting having been noticed in Road, P.C., it is sufficient here to advert to the necessity of securing a firm solid foundation, whenever the ground is soft, must be accomplished by ramming, or by removing the soft earth, and substituting a coarse concrete, consisting of seven parts of deep river-sand or gravel and one part of grey stone-lime, fresh ground to a fine powder, these materials, together with mastic dry, and water when necessary, only or mixed with oil, should be added to moisten the mass, which must be immediately thrown into its place, levelled, and rammed solid. A much finer concrete should then be floated over the surface to fill in the hollows and crevices, which should be allowed to dry before laying the asphalting, which, if this precaution be neglected, is liable to be full of air-holes, in consequence of its heat converting the moisture of the concrete into vapour. The risk of such failure may be diminished by sifting fine sand over the concrete when dry. Under these circumstances is sure, and in rainy weather, if the work cannot be protected with tar-papling, which is highly desirable, injury may be prevented by laying sheets of brown paper, tacked on the under side, between the coats of mastic. Mastic is regulated by gauges or slips of wood, which are laid down so as to divide the pavement into compartments, seldom exceeding, where but one person is employed to spread the mastic, thirty inches wide (though in very cold weather the latter or portions of mastic may be double that width, and two spreaders may work together), and the composition of

P. C., No. 19.
second layer of equal thickness will complete the work, and fill up defective places caused by the blistering of the first. A more effectual way, which may even be resorted to in situations exposed to the heat of the sun, is to build a new half-brick wall of asphalted bricks, set in mastic, adjoining the wall to be protected, filling the intervening space with mortar or cement. If water percolates through the original wall towards the new wall of asphalted bricks, asphalted tiles, set in Roman mortar, may be applied as a filter to the wall, and to their asphalted surface the new brickwork may be laid solely with mastic. The lining of tanks and reservoirs is an operation so similar to the above as to need no detailed notice. If a pitch of flat spandrils be covered with fine asphalt, laid upon a thin coat of fine concrete, supported by a rough boarding of dry wood. It is well in such cases to cover the concrete with canvas, and to remove the concrete for a width of about three inches wherever the mastic is applied, to allow the water, supplying its place with asphalt, so that if water should percolate at the joint in the upper coating, it will be unable to penetrate further. The lines of junction with walls must also be carefully secured by a kind of flashing, and scooping out the mortar to allow the asphalt to take hold of the brickwork; or, in the case of a stone wall, by cutting a groove to receive the upper edge of the flashing or fillet of mastic. It is recommended that, where roofs are not intended to be walked upon, and especially where the walls are exposed to the sun, the surfaces should be strewed with grit, as above described for rough pavements. Respecting the covering of arches, it is sufficient to observe that the asphalt may either be applied immediately to the saving brickwork forming the extrados of the arch, with an intervening thin coat of fine concrete; or the spandrils may be filled with concrete so as to form a level surface for the arch, even with the crowns of the arches; or, advancing a step further, the concrete may be laid up to the level of the roadway, and the covering of asphalt be used as a pavement, as well as for the exclusion of water. On the Greenwich Railway viaduct, upon which a surface of 480,000 square feet has been covered with mastic, an intermediate plan has been adopted; the asphalt being laid in an undulating surface, with a full easy way.

In whatever way asphalt may be applied, the greatest care is necessary to secure a solid foundation, to ensure the dryness of the concrete or brickwork to which it is applied, to use the mastic as hot as possible, and to make the joints perfect. Wherever any part needs repair it may be softened by laying some hot mastic upon it for a short time, and then cut away with a chisel without injuring the adjacent parts. The old mastic may be remoulded, and, the edges of the old work being cut square, the hot material will readily adhere to them, if they are carefully freed from dust and moisture. It only remains to notice that the thickness of asphalt used for pavements varies from half an inch to about an inch and a quarter, the mastic being soft for commercial purposes, not intended for carriages, and from three-quarters to an inch being the least allowed for carriage pavements; half an inch to five-eighths is sufficient for roofs and the covering of arches to prevent the infiltration of water, and for the lining of tanks and ponds; and about half that thickness is sufficient for covering the ground-line of brickwork, to prevent the rising of damp.

ASPIDIADIA (Preal.) Several species of the Lepido
dendra of Sternberg are thus named. From the coal forma
tion.

ASPIDIUM, a genus of Ferns, and one under which many species were arranged by older botanists, which are now placed under the name of Pteridium. For an account of the male and female genera see Filicae, P. C. S. One of the most remarkable species of this genus is the Aspidium Boreale, or Tartarian Lamb, recently referred by Mr. Smith to the genus Cibotium. This plant, from its peculiar colour and form, was at one time really supposed to be a kind of vegetable animal, as the follow

ing account from Struys, an old traveller, proves: 'On the western side of the Volga,' he says, 'there is a elevated salt plain of vast extent, but wholly uncultivated and uninhabited. On this plain, to complete the features of the scene, there is with salt, grows the Boranace or Bornitech. This wonderful plant has the shape and appearance of a lamb, with feet, head, and tail distinctly formed. Boranes, in the language of Mus
covy, signifies little lamb, and a similar name is given to this plant, as it is called the little lamb, and written down as some silk. The Tartars and Muscovites esteem it highly, and pre

serve it with great care in their houses, where I have seen many such lambs. The sailor who gave me one of these precious plants, found it in a wood, and I had its skin made into an under-waistcoat. I learned at Astrasch, from those who were best acquainted with the subject, that the lamb grows upon a stalk about three feet high; that the part by which it is sustained is a kind of navel, and that it turns itself round, and bends down to the herbage which serves for its food. The leaves are very little divided, and end at least in the grass sails. Struys adds many other wonderful things about this plant. His statement is however substantially correct. The rhizome of the A. Barones renders a rude resemblance to an animal. It is covered with a silky down, and when cut into has a soft inside with a beautiful flesh-coloured appearance sufficient to account for the origin of the fables with regard to its animal nature. It is not improbable that this fern dries up when the grass does, but of course the one has no dependence on the other. The plant is a sprig, and the astringent property which is common to all ferns; hence its name. Dried specimens have sometimes been brought to this country, but the plant has not yet been brought alive.

Aspidium filicis alias (now Lastra filicis Mus), the male
fern, is a native of Great Britain, and is admitted into the British Pharmacopoeias on account of its anthelmintic proper

ties. It has bipinnate fronds, obtuse and serrated pinnules, the sorii near the central nerve, the lateral nerves forked. It is abundant throughout Europe, and grows in stony places on the roofs of old houses, and on earthy banks of streams. The part used in medicine is the root, or rather the rootstock. This

part of the plant is collected for medicinal purposes between the end of May and the middle of September. It will not be found in any considerable quantity after the end of August. It has often been chemically analysed, and is found to contain,

Lignin 45
Starch 10
Arsenical sugar 10
Gum 7
Fixed oil 4
Resin 4
Sols, volatile oil 8

The antients used this plant as a vermicifuge, but it was

not lately given up by modern practitioners of medicine when

Pecchioli pointed out the conditions in which he had found it efficacious in expelling tape-worm. The best mode of ad

ministering it is an urchinal tincture: the adherent seems
to dissolve up the resinous oil on which the active properties

of the plant depend. The dose of the root according to Pecchi

is about one dram.

A. dilatatum (Lastra dilatata), a British fern, is often

found with the last for medicinal purposes. It has subtri

pinnate fronds; oblong, blunt, inciso-pinnatifid lobes; spinose, mucronate segments; a decided unfringed inclusion. This is common in joy. It is found common in dry corners of our

woodland. The part used is the fronds.

A. filicis-seminis (Athryum filicis-Rhynia), Lady-Fern, has

a lanceolate pinnate frond; plane linear, acute, regularly pin

nate; pinnules linear-oblong, quite distinct, deeply serrate or pin

nitidum; segments with 3-2 teeth. This is one of the most

beautiful of the British ferns. The root is sometimes gathered

for that of the male fern. It has a short perpendicular root

stock, black externally, with black root-fibres; and the tufts or

bases of the leaf-stalks, which compose the greater part of it,

form a very acute angle with its axis, while those of the male

shield-fern extend outwards at a more open angle.' (Christi

on.)

ASPIDORRHYNCHUS, a genus of fossil Ganoid fishes, from the Ilias and oolle of England. (Agassiz.)

ASPIDURA. A fossil species of ophichthid Echinoder

thomas is thus named by Agassiz. From the Ilias of Yorks

shire.

ASPLENIOPTERIS (Sternb.). [Pterophyllum, P. C. S.]

ASPLENIUM, a genus of plants belonging to the na

ture of the road to Scotland, containing compound

straight sori, with an indusium opening towards the central

nerve or midrib. The species of this genus are known by

the name of Spleenwort; several of them are common in

Great Britain.

A. lanceolatum of Udace has lanceolate doubly pinnate

fronds; the pinnules ovate and deeply and sharply toothed, or lobed; the sori short, nearly marginal. It is a native of
England and Wales, on rocks and walls, but its distribution is very local. It is also a native of France, but its European habitats are few.

A. Adiantum-Nigrum, Black Spleenwort, has triangular attenuated fronds, twice or thrice pinnate, the pinnae and pinnules triangular, sharply toothed; sori elongated, central. This plant is a native of Europe, and is abundantly distributed throughout the United Kingdom, where it occurs on rocks, walls, in two or three classes, sometimes in abundance. It is much used in medicine, and is stated by Ray to be efficacious in cough, asthma, pleuritis, jaundice, stone, gravel, and other diseases. It has not however any reputation amongst modern practitioners of medicine.

A. Blackstoni, Wall Rue, has bipinnate fronds, the pinnules rhomboid wedge-shaped, notched or toothed at the end; the indusium jagged. This fern is very common on rocks and old walls, in Great Britain and throughout Europe, and in many parts of North America. It has sometimes been used as a remedy in coughs and asthma, obstructions of the liver, and in cutaneous diseases; but has now fallen into disuse.

A. Trychomus, Common Spleenwort, has pinnate linear fronds; roundish ovate, crenate, stalked pinnae; the nerves forked below the sori. It is very common throughout Great Britain on rocks, walls, churches, ruins, bridges, and hedge-rows. It is a native also of Europe, Africa, and the United States, and is one of the most useful of our ferns. It is not included in any of the previous species but has now entirely disappeared. Other British species of Asplenium are A. alternifolium, A. septentrionale, A. marinum, A. ciliatum, and others.

These and other ferns may be easily cultivated, by placing them in situations resembling their natural habitats. They require a pure atmosphere, plenty of space, and natural shade, with a due supply of water. They may be planted on decayed wood, in holes of rocks and brick, with almost any soil. One of the most elegant modes of cultivating them is by means of inverted jars, under which they will thrive in any sandy or light soil. Cases well adapted for growing ferns are constructed on this principle, constructed according to directions laid down by Mrs. G生活中, it has the merit of having first suggested this mode of growing plants.

(Babington, Manual; Newman, History of British Ferns; Ward, Growth of Plants in Glassed Cases.)

ASSAULT in Scotland a punishable offence, usually prosecuted by the public prosecutors to the sheriffs courts, to the police courts established by statute, and to the justice of peace courts. It is seldom brought before the supreme criminal court, unless it be of a highly criminal character, when the case, according to the circumstances, is tried either as a capital or as a civil cause; but it is not a capital crime in Scotland. The 6 Geo. IV. c. 196, however, relative to assaults connected with combination, applies to that part of the kingdom. The respective punishments of the various kinds of assault have thus, in Scotland, been in a great measure fixed by the practice of the several criminal courts.

AST, GEORGE ANTON FRIEDRICH, an eminent German scholar, was born in 1778 at Gotha, at the gymnasium which place he was educated. In 1792 he entered the University of Jena, where he remained almost entirely to philosophical and philosophical studies. In 1802 he began his career as an educational lecturer at Jena; and in 1805 he was appointed professor of ancient literature in the University of Landshut, where he remained until the transfer of that institution to Munich, in 1812. He spent the remainder of his life at Munich, where he died on the 30th of December, 1841.

AST was one of the best and most industrious of modern scholars, and a very excellent teacher. His merits were recognised and rewarded by various distinctions which the Bavarian government conferred upon him. He occupied himself not only with philology, in the strict sense of the word, but also with several departments of philosophy and its history, and these merits led him, during the latter period of his life, to devote himself almost exclusively to the study of Plato, for the understanding of whose works he has done more than any other scholar. His numerous works may be divided into the following classes:---(1) Works on the life of Plato; (2) Works on the Writings of Plato, among the former we must notice especially his 'Handbuch der Ausgewisse,' Landshut, 1807, 8vo.; 'Grundliicn der Philologie,' Landshut, 1808, 8vo., an excellent introduction to the study of antiquity; 'Grundliicn der Grammatik, Hermeneutik und Lexikion,' Landshut, 1808, 8vo., a most valuable work on the Grammar of the Greek Language; 'Philosophie,' 2nd edit., Landshut, 1825, 8vo., a very good introduction to the study of philosophy; 'Hauptsliicn der Geschichte der Philosophie,' Munich, 1829, 8vo.; 'Plato's Studies in Greece and Sicily,' Munich, 1834, 8vo., a work on the travels or works on Plato that have been written in modern times, and forming a very useful introduction to the study of that philosopher. Among his philological works we may mention 'Observationes in Proprieti Carminis,' a youthful production which he published before entering the university in 1798. In 1809 he began editing a number of separate dialogues of Plato, such as the 'Phaedrus,' 'Symposium,' 'Alcibiades,' 'Laches,' and others, which were well received; and this led him to publish in 1810 the complete edition of Plato's works in five volumes (Leipzig, 1819-32), in 11 vols. 8vo., with a Latin translation, and a commentary which occupies the last two volumes. He next published, as a sort of supplement to this edition, a 'Lexicon Platonicum,' Leipzig, 1854-59, 3 vols. 8vo., which is regarded as one of the best and most valuable of the critical point of view, his edition of Plato is greatly surpassed by some of the more recent editions of that philosopher.

(Biographical Dictionary of the Society for the Diffusion of Useful Knowledge; Brockhaus, Concise-Lexicon, 9th edition.)

ASTERACANTHUS, a genus of fossil Plicoid fishes, including five British species, from the colitic and lia formas.

Asteraceae. (G ammunition.)

ASTEROHYLLITES (Brongniart), a genus of fossils, containing many species, from the coal formations of Europe and America.

ASTEROPYTHUS, a genus of fossil Plicoid fishes, from the mountain limestones of Ireland.

(Aston.)

ASTLEY, JOHN, a portrait-painter, born at Wem, in Shropshire, in the early part of the eighteenth century, more distinguished for his good fortune than for his works, though there is no doubt that he possessed a great deal of merit, especially those of his earlier years. He was the fellow-pupil of Reynolds with Hudson, and was at Rome also at the same time with Sir Joshua. He was very poor when studying in Rome; and Northcote, in his Life of Reynolds, tells a story of him that is well known to all. One day, in the summer of a summer's evening ramble near Rome with other English artists, his companions took off their coats and advised Astley to do the same, to which he objected; and his persisting to keep his coat on appearing unaccountable to them, caused them to make some jokes at his expense, which at last forced him to follow their example, when the mystery was out,—the back of his waistcoat was made out of one of his own sketches, that the poor painter, with a waterfall on his back, made a ludicrous figure, which afforded his companions a hearty laugh.

After his return to England he spent a few months in London, and then tried his fortunes in Dublin, where he practised with such success that in three years he saved £2000. He considered this capital sufficient to enable him to venture his fortunes in London; and 'as he was painting his way back to London,' says the writer in 'Adams' Biographical History,' 'in his own post-chaise, with an outrider, he loitered with a post-horse through various villages, and arrived at the visited Knutsford Assembly with another gentleman. Lady Daniel, a widow then present, was at once so won by his appearance, that she contrived to sit to him for her portrait, and then made him this offer of his hand. He was the latter of Sir William Daniel, and was possessed of a very large fortune, the whole of which she bequeathed to Astley, besides the reversal, at her daughter's death, of the estate of Addenfield Lodge, Cheshire, worth 8000£. a year. The Lady Daniel died not long after her marriage, and her daughter did not survive her many years. Astley obtained possession of
one property, and gave himself up to a life of pleasure. He purchased the house in Pall Mall which had belonged to the Duke of Schomberg, of which Persimmon, in his 'London,' says, 'I have possessed myself or divided it into three, and most whimsically fitted it up for his own use.' He fitted up also a villa at Barnes, in Surrey, according to a peculiar fancy; and he made many improvements at Ducket Lodge. After a life of pleasure, as he was growing old, be married again, a young lady, by whom he left two daughters and a son. He died at Ducket Lodge in November, 1787. Before his death his character changed; he regretted the part he had adopted; he led the life of a man who had profiting the case; and what was formerly called the gate of the New Agora, is proved both by its style and inscription, not to have been a gate, but part of a building erected out of the donations of C. Julius Caesar and Augustus to the house of the Archons. That which is now the Agora is supposed to have been, was in the time of Theodidas not occupied by houses, but consisted of garrets. (Thucyd. ii. 171; Xenoph. De Vetears. 2. 6.)

The form and basins of the Port of Piraeus have been the subjects of much discussion, and the late Professor Ulrichs endeavoured to establish an opinion which was solely opposed to that of Leake, as well as to the later one of Ones. but it is as yet impossible to say which of the conjectures of Leake and of Curtius, or of Ones and of Halle, 1842, 8vo.; Ulrichs, O lyamin et ro malis trigv ypepov, Athens, 1843.)

We cannot here upon an explanation of the main point; but we shall only give a few of the most interesting discoveries, and corrected by late investigations; the student must refer to the works quoted at the end of this article. We shall sit only a brief account of the most interesting discoveries that have been made at Athens. The Acropolis is the only place in which excavations have been made on a large scale, with something like systematic order. Operations were commenced there in 1833 by a private society of antiquaries. The year after, when Athens was made the capital of the kingdom of Greece, the government took the work into its own hands. The excavations were conducted by the celebrated German architect L. von Klenze, and afterwards by Professor Ross, assisted by the architects Schaubert and Cleasine, whose place was soon after supplied by Iliass. Ross was succeeded in 1836 by Pittakis. The results of the excavations down to 1843 are briefly but well described by Curtius, Die Akropolis von Athen, Berlin, 1844, 8vo.

The operations in the Propylæa began in 1834. The first thing that was done was to remove the modern constructions which blocked up the entrance to the Acropolis. The great upper battery which extended from the pedestal of the statue of Agrippa in the north to the corner of the Cimiezian wall in the south, was next taken down. The discoveries there made were the most interesting of all. The temple of Victory unvilled (Nike Apteros) were found almost complete, and very little injured; many fragments of the Propylæa, consisting of sculpture and pieces of architecture of every kind, and the whole burnt them in one whole district in view of Athens. A considerable part of the marble flight of steps leading to the Propylæa was laid open at a somewhat later time.

In the winter of 1836-37 operations were commenced in the Propylæa itself; the central part and the northern wing were cleared from the modern constructions built in them, and then the battlements which had been erected upon the walls in the middle ages. In the central part, the six Ionic columns of the vestibule are still standing, though only about two-thirds of the height of the temple are still standing; the parts of these columns, however, which had fallen down, were found among the ruins, but the capitals are much damaged. The northern wing is in perfect preservation up to the cornice; and the tower of the southern wing is still standing, but no trace has been found of any of the temple of Victory saw in the Propylæa. The most remarkable discovery is that of the temple of Victory mentioned before. As all the fragments were in a state of almost perfect preservation, it cannot be said that there is much difference between the temple as it stood in ancient times and as it still stands; it was probably taken down by the Turks in 1684, for the purpose of using the masonry in constructing the great battery. Out of all that thus remained, the attempt must be made to reconstruct this beautiful edifice, and in 1836 the restoration was nearly completed. It was conceived by Ross, Schaubert, and Hansen, but after the withdrawal of Ross in 1838 the progress was somewhat delayed. At present however, the restoration is complete, and the temple of Naxus which claim this honour. The most probable opinion is, that he entered Athens by the Pireas gate, between the Museum and Pnyx, as is sufficiently expressed by Stuart, who has recently been completed by Müller, Forchhammer, and Curtius.
once more is seen in its full beauty; it serves as a temporary Museum in which some of the newly discovered relics of antiquity are deposited.

As the government had resolved upon clearing the whole plateau of the Acropolis from the rubbish, and modern buildings, excavations were also made in and around the Parthenon. Here were found most valuable fragments of the metopes, the frieze, and of the statues in the pediments, which are deposited in the building of the southern excavations of the Acropolis. In 1842 the mosque which had been built within the cells of the Parthenon was cleared away, and the place where the temple-statue had stood was found. The area on the eastern side was cleared, namely the foundations of the north half. Now that the cells of the new Hermes Street. This, which may be considered the main street, extends through the city from east to west, and two other principal new streets, Zéolus and Athene streets, run into it on its north side. The new street called Stadion seems to be the principal one in the city. The whole is now deposited in the temple of Theseus and other places, and whatever others may either happen to be discovered or to be purchased by the state; also models of the ancient buildings are remaining in a state of decay.

ATMOMETER. called also Atmometer or Atmosmeter (from der, a 'vapor,' and μέτρον, a 'measure'), an instrument employed to measure the quantity of exhalation from a humid surface in a given time. Allusion is made in the ' Athenian Constitution' of Pericles (309 B.C.) to a kind of thermometer described by Professor Richman (in the Nov. Comment. Petrop., vol. ii. p. 121), with the nature of which we are unacquainted; but the instrument to which the name is usually applied is one invented by Professor Leslie, which consists of a very thin wall of porous earth, and two or three inches in diameter, to which is cemented a long tube of glass, marked by a division with divisions, each of which is capable of containing as much liquid as would, if spread over the outer surface of the tube, form a film in thickness equal to the sixth part of an inch. The open end of the tube is fitted with a brass cap and a leather collar; and when in use the instrument is filled with distilled or boiled water, and suspended vertically with the ball downwards, the end of the tube being perfectly closed with the cap and collar. The water then percolates through the porous ball precisely in proportion to the evaporation from its outer surface, of which its weight in the tube forms an accurate indication. The vacuum in the tube, caused by the evaporation, and the pressure in the operation, gradually filled with air which enters through the porous ball. When the tube becomes empty, the cap is removed to re-fill it. This instrument is not only useful in meteorological observations, but is also capable of being applied with advantage to topographical operations, and in the application of science to agriculture.

ATMOPHERIC RAILWAY. In a brief sketch of the history of this invention, a lecture delivered by Mr. Vignoles (then professor of civil engineering at University College, London), to the Royal Cornwall Polytechnic Society, in October, 1842, that gentleman observed that the idea of producing motion by atmospheric pressure was conceived by Papi, the well-known French architect, two or three centuries since; and that, after slumbering for more than a century, the subject had been successively taken up by Messrs. Lewis, Medhurst, Vallance, and Pinkus, and lastly by Mr. Clegg, by whom, in connection with the late Mr. Jacob Samuda, the beauty of the idea was thoroughly proved.* Of the connection of the name of Lewis with this invention the writer has no other intention; but the publications of the late Mr. Medhurst, who was a practical mechanician or engineer, and well known on business as the inventor of an ingenious printing-press, show that he not only cherished the idea of locomotion by atmospheric pressure for many years, but also devised, among other plans for its accomplishment, one which, excepting in practical detail, greatly resembles that of the present writer. Mr. Medhurst published a short account of his scheme in 1810, under the title of ' A New Method of Conveying Letters and Goods by Air,' and in 1819 he issued another pamphlet of calculations and remarks, 'to prove the safety, cheapness, and advantages of such a mode of conveyance; but, as he observes

* A condensed report of this lecture, originally published in the 'Cornwall Gazette,' appeared in the 'Railway Times' of Oct. 9th, 1842.
In a more recent work, 'these publications met with that indifference and contempt which usually attends all attempts to devote so widely from established customs.' In the pamphlet from which this remark is quoted, which was published in 1827, entitled 'A New System of Inland Conveyance of Goods and Passengers,' is a full account of the various modes in which it was proposed to accomplish the desired object, the principal of which were, first, the construction of an air-tight tunnel of sufficient magnitude to admit the passengers and goods to be conveyed in it, running from the place where it was proposed to be opened to the dynamic traveller, which was impelled forward by the pressure of the atmosphere in its rear whenever, by the means of pumping machinery connected with the tube, a partial vacuum was produced in the front of the tunnel, and by the admission of sufficient air to the rear. Within this tunnel, running parallel to it, was placed the dynamic apparatus, by which the vehicle was drawn, and immediately after the passage of this connecting-rod the valve was restored to its place, a sides being freshly lubricated by an apparatus attached to the governor, and the whole being pressed firmly down by wheel or roller. In this form of the apparatus the governor and the carriage attached to it ran upon rails attached to the external sides of the tunnel, and, as the mean of propelling a second carriage, for passengers, running upon a railway either above or alongside of the tunnel, in the open air; and, fourthly, the construction of a railway or tram-road, in the centre of which should be laid a still smaller air-tight tube, containing a travelling piston which should be connected, as in the last-named contrivance, with an exterior carriage, the modes in which it would be necessary to unite the carriage outside the tube with the piston within it was by an air-tight water-valve, which however would only have been applicable on a perfect level, and with a very low pressure of air, so that another apparatus, to all levels, was formed by thin elastic sheets of iron or copper, shutting down upon a soft substance, so as to form an air-tight joint, but capable of being readily lifted up to allow the passage of the connecting-bar, by the action of a wheel connected with the piston. In all cases it appears that the apparatus had to have contemplated moving the piston by forcing air into the tube behind it, and thereby forming a plenum, in preference to forming a vacuum by exhausting the tube in advance of the piston. It was also necessary to have a very independent idea of the degree of atmospheric pressure necessary to produce rapid motion, imagining that in a tunnel of thirty feet sectional area carriages might be propelled at the rate of sixty miles per hour without the condensation of the air becoming uncomfortable to the passengers, who, according to his original plan, would not have been shielded from its effects.

Before the publication of the last-mentioned pamphlet of Medhurst, but many years after the original promulgation of his principles, a railway of the above public interest proceeded to a similar project, which, being brought forward at a season of extraordinary speculation, excited much interest, as well as little ridicule. Van'sche's scheme, which was fully explained in a pamphlet published by him in 1825, entitled 'On the Exploitation of Railways,' was, like Medhurst's original design, for conveying passengers along a railway laid within an air-tight tunnel, which he proposed to construct either of cast-iron or of vitrified clay, resembling common brickwork, but less permeable to air; but, knowing that experiments had proved a very great loss of power from result to the attempt to impel air through a long pipe, he proposed to set the piston-carrying in motion solely by exhausting the tunnel in advance of it, and sufficient force of vacuum should be capable of the purpose required. This plan, which was patented in 1825, was brought into experimental operation at Brighton upon a sufficiently large scale to prove the possibility of so singular a mode of transportation. But it is difficult to determine whether there were any difficulties in the objections of the travelling public to transmission in a dark tunnel would have proved sufficient to prevent its general adoption.

About the year 1825 the subject was revived in consequence of the great success of the Liverpool and Manchester Railway, the passengers of which seemed to have left off the idea of travelling by inland tunnel. In their place, in 1825, there was laid a line of only 11 tons cwt. in two carriages. This experimental line, which had an atmosphere of only nine inches diameter, was publicly exhibited in action at intervals, for many months.

The first half of 1844 and the whole of 1845 was occupied in constructing and laying down the line of this important railway, the intention of which rendered it unsuitable for working by locomotive engines. This line, which was so far completed as to be ready for working in August, 1845, is at present (December, 1844) the only one of atmospheric railways in the country whose first-mentioned line having been removed to allow the completion of the West London Railway, which is worked by locomotives; but though no other lines are yet made, the London and Croydon Railway Company have recently obtained parliamentary sanction to a plan for laying down a line of atmospheric Railway along side of their present road, from London.
to Croydon, and making an extension of the same from Croydon to Epsom, by which arrangement there will be a complete atmospheric line of about 18 miles, half of which will run parallel with and close to a railway worked by locomotive engines. Thus affording the most favourable conditions for comparison between the two modes of transport.

A further line from Epsom to Portsmouth, and several other projected railways of considerable extent, are also proposed to be constructed in this manner.

The most important point in which the atmospheric railway of Messrs. Clegg and Samuda differs from previous contrivances of the like character is the construction of the valve, which, even when the speed of the piston and train is increased to 60 or 60 miles per hour (a speed frequently attained in experiments upon the Dalkey line), performs its office with surpassing efficiency. The subjoined diagrams, without pretending to give minute details, will show the nature of this contrivance: Fig. 1 representing a cross-section of the valve open, and Fig. 2 with the valve closed, to Fig. 2, with the passage of the connecting-bar between the piston and the external carriage. The tube, which is formed of cast-iron, in convenient lengths, and flanged together, is laid in the middle of the railway track, and closely lined on each side with two pieces of iron, the undermost of which exactly fits the slit in the pipe, and has its lower surface concave, so that when it is shut down, as in Fig. 1, the internal circumference of the tube is perfect and unbroken, while the upper parts have been retracted, and it prevents the valve being forced into the tube by the superincumbent pressure of the atmosphere. The leather is, on the side marked b, considerably wider than the upper plate, and its projecting edge is attached to the flat floor of the valve-trench, at the base of the valve, so as to form a continuous hinge. The more perfectly to prevent the ingress of air, the opposite or opening edge of the valve, is when closed as in Fig. 1, hermetically sealed with a composition of wax and tallow, which fills the small groove or space left between it and the edge c, and is indicated by a dark mark in the cut. To protect the valve more thoroughly the trough is closed in with a sheet-iron cover d, formed in lengths of about five feet, with lap-joints, lugged with leather to the top of the edge d, and shut down closely upon the top of the edge c. The interior of the tube is completely lined with a soft composition, which fills up all little irregularities, and renders the passage perfectly smooth and even; and the piston is surrounded by leather collars in such a way as to be perfectly airtight, and yet to move with very little friction. It is attached to the edge e of a rod which is seen in section at f (Fig. 2), and which carries rollers so fixed as to lift up and open the valve when the connecting-bar has passed, thus bringing it into the position indicated in Fig. 2, which allows room for the passage of the connecting-bar e, by which the piston is united to the foremost carriage of the train; the iron cover d being previously raised and held open by a coulter and a series of wheels or friction-rollers attached to the carriage. After the connecting-bar has passed, a roller attached to the carriage presses the valve down into its seat, while a heater gliding along the mass of composition at its opening edge melts it, and thereby seals the joint already formed. The air is thereby allowed to fall into its place, and all is ready for the passage of another train so soon as the piston shall have quitted the pipe so as to allow of its being exhausted afresh. The end of the valve being in a horizontal line, to admit the air by which the piston is to be impelled; but on the admission of the train is closed, and the air is pumped out from the pipe by a branch pipe near it, leading to the air-pumps, which may be worked either by a steam-engine or by any other prime mover. It is proposed, in an extended line of railway, to place engines at intervals of two or three miles, and to break or interrupt the continuity of the atmospheric tube at the principal stations, so as to allow of the use of switches, turn-tables, and the other ordinary arrangements of a railway station; but it is needless here to enter upon an explanation of the various means by which these objects are accomplished.

It is sufficient to observe that the train is pushed forward by manual labour until the piston has entered the tube, which it may do, by the aid of an ingeniously contrived valve, without impairing the partial vacuum which may have been previously produced in it; it then advances with a speed proportionate to the rate at which air is admitted through the air-pipes, at the opposite end of the tube, where, without the aid of an antagonist, the valve which has closed the tube flies open, and the piston and train proceed by momentum until they are stopped by brakes if requisite, or, if it be desired to pursue the journey without stopping, by pistons engaged in the piston pipe. As soon as it has passed out of the first length, the end-valves are again closed, and the engine immediately commences the rarefaction of the tube in readiness for another train. Both in the experimental line at Woodrow, in the tube and the atmospheric railway at Dalkey the inclination of the road is sufficient to produce rapid motion in one direction by gravity alone, so that the atmospheric pressure is only required in ascending, while in descending the piston is moved against in such a way as to clear the way and compensate for the mode of propulsion is equally applicable to working in both directions, either by means of two separate tracks, each having its own atmospheric tube, or by a single track and tube, along which the piston is impelled alternately in either direction.

While the opinions of leading engineers continue at variance as to the merits of this mode of working a railway, it may be well to say very little of its proposed advantages. Some of it is claimed that it claims in this mode of working to be far superior to the stationary by stationary instead of locomotive engines [Railway, P. C., vol. xix., p. 260], of which the principal are the facilities which it affords for ascending steep gradients, and is consequently for the conveyance of railway goods at less cost. Vast heavy cuttings and embankments are avoided, in order to procure easy slopes for the locomotive; the saving in the wear and tear, and consequently in the necessary strength and cost of the railway itself, in consequence of not having to convey the moving power with the train; and the security against collision, owing to the impossibility of moving two trains on the same stage or engine-length of railway at the same time. In like manner also some of the objections raised to this apply to every mode of using stationary engines: such are the necessity of providing and constantly maintaining a power sufficient to conduct the largest amount of traffic which can ever be conveyed, which would render it as costly, as regards some large items of expense, to maintain a railway for the passage of four or five trains as fast as upon which trains are constantly succeeding each other; and the liability of derangement to the whole system in consequence of the failure of a single point in it. These are the superficial grounds which belong to the question of infallibility of the system, or, in other words, the comparative want of power to modify the mode of working according to the fluctuations of a variable traffic or the exigencies arising from accident. In drawing a comparison between atmospheric and rope railways it is less fitting in some points the merits and demerits of the two are identical. The vacuum in the one supplying the place of the rope in the other, it cannot be questioned that the train of an atmospheric railway keeps the road more free from accident, especially upon curves, it being as it were tied down to the track by the piston travelling within the tube; and also that,
the difficulty of producing a valve which shall open with sufficient facility and close with sufficient exactness being once overcome, which it appears to be most perfectly, the friction and waste of power must be less in the atmospheric system, where a single rope and a long series of pulleys have to be put and kept in rapid motion; to say nothing of the chances of accident by the breaking of the rope, to which there is no equal risk as a parallel objection to the atmospheric system. Indeed one of the greatest advantages claimed for this mode of working a railway, as the worst which could happen in consequence of the failure of the apparatus would be the stopping of the train. In case it should be necessary to stop in the middle of a line of stations, the brakes will generally be found sufficient for the purpose, as there is not the immense momentum of the heavy locomotive to overcome; but it is proposed, if needful, to introduce a safety valve in the piston, or an arrangement for lifting his in front, in case of emergency. It is proposed generally to lay out atmospheric railways so nearly on the natural surface of the ground as to take advantage of many slopes of sufficient steepness for working by gravity alone; but while this has been much insisted upon by some advocates of the system as an advantage, it appears to be too little remembered that the advantage gained in one direction must inevitably produce a corresponding disadvantage in traversing the line in the opposite direction, and some of those who have questioned the economical application of the atmospheric in lieu of the locomotive system, consider it well adapted for use upon such inclined planes as have hitherto been worked by ropes or by assistant engines.

Another advantage which is claimed by Mr. Attiret upon the early plans of atmospheric propulsion may be obtained from the pamphlets alluded to in this article, and, so far as those of Pinkus are concerned, from the Railway Magazine, First Series, 1856-6, and Second Series, vol. 1. 1856, and Herber's Engineer's and Mechanic's Encyclopaedia, vol. 1. pp. 35-40. Clegg's atmospheric railway has given rise to several pamphlets, chiefly of a controversial character, and, especially in connection with the Croydon and Epsom Railway Bill of 1860, the controversy may be said to have been settled by parliamentary committees; but the most complete body of information on the subject, with accurate records of the principal experiments at Wormwood Scrubs and at Dalkey, will be found in the columns of the Railway Times, from 1840 to the present time.

ATRIPLEX, a genus of plants belonging to the natural order Chenopodiaceae and the tribe Atripliceae. It has monocious, rarely perfect flowers, the perigone of two or less connected parts, two stigmatic branches, and two carpels; the seed is vertical, attached by a lateral bilum, either near the base or by means of an elongated funiculus in the middle of the side; the radicle basal; the stamens five, continuous. Most of the species of this genus are annuals and perennials, and are abundant in pastures, as well as in corn-fields. Bahnhong, in his 'Manual of British Botany,' enumerates ten species as inhabitants of Great Britain. The most common forms of the genus on cultivated lands are A. aquatica, A. erecta, A. prostrata, A. littorea, A. portulacastrana. Bahnhong has described recently a new species, which is also found in cultivated and waste places, not uncommonly in Great Britain. This is A. deltoidea (Bab.): it has an erect stem with spreading branches; opposite leaves, all hastato-triangular, with two descending lobes unequally acute on the sinus-dentate; the perigon of the fruit ovato-triangular, dentate, tunicated on the back, rather longer than the fruit, collected into a many-flowered, branched, dense panicle; seeds smooth, shining, A. rosularis, a frequent plant along the sea-coast. A. prostrata is a coast plant, but is rare in Great Britain, and Bahnhong suspects that it may be a maritime form of A. patula.

(Bahthon, Manual of British Botany.)

ATTIRET, an aforesaid, a subdivision of the great genus Terebratula, chiefly (if not entirely) confined to a fossil state, and to the Palaeozoic strata. Many of the Siphiriodes Sowerby (as Sp. glahm, fimbrata) and some of the Terebratula of the same authority (as uterus) have been referred to the very ill-characterized genus T. pitticosa is the recent analoge.

ATTENDANCE TERM. [TERM OF YEARS, P. C.]

ATTIRET, JEAN DENTS, called Frère Attiret, a French painter attached to the Jesuit mission at Peking, in the year 1760, was born in the Franche-Comté, in 1702, and was first instructed by his father, an obscure painter of Dôle. He completed his studies at Rome, whither he was sent by the Marquis de Brois. After practising a short time at Lyon, he settled at Avignon, and became a lay-brother of the Jesuits of that place; and when, in 1770, the French Jesuits of Peking requested their brothers at home to send them a painter, Attiret undertook to go, and set out in the same year.

In China Attiret soon obtained the favour of the emperor Kien Loong, by presenting him with a picture of the Adoration of the Kings, which he ordered to be placed in one of his own apartments; he however expressed a dislike to the glass of oil, and employed Attiret only as a water-colour painter. But the right to execute the works of art, whether in oils or even in wood, was reserved to a painter, an order he received from the emperor to restore a painting in one of the inner apartments of the palace, a commission as disagreeable as it was honourable to the French painter. He was locked up in the room from seven in the morning until five in the afternoon, with several eunuchs, entirely in attendance on him, but really as a guard over him. Palace etiquette would not allow him any convenience, and he was compelled to work in constant danger of breaking his neck, as a chair placed upon a table was a deadly scaffold he could procure. In addition to these evils, he was forced to leave his dinner and content himself with fruit and biscuits, as the emperor, in consideration of his great ability, sent him his dinner daily from his own table, but before it reached Attiret, was usually cold and spoiled. Attiret himself, in passing to and from the chamber in which he was at work, was obliged to deliver himself into the hands of various sets of eunuchs, and was wont to be molested locking and unlocking the door.

Attiret met also with many vexations from the Chinese court painters until he employed them to execute the secondaries portions of his works, and confounded himself in some degree to the Chinese taste. He found that the Chinese painters executed the costume, landscapes, and even animals, much quicker and quite as well as he could do himself.

Between the years 1763 and 1760, when the emperor Kien Loong was at war with the Tartars on the north-western confines of China, Attiret was ordered to return to France, and prepare some designs to illustrate his triumphs. Attiret arrived at the seat of war in 1754, and made many accurate drawings of triumphs, processions, festivals, &c., from which he afterwards painted pictures, some of which were preserved in the palace, and shown only by special permission of the emperor. Attiret painted the emperor's portrait, and introduced a great many portraits into these drawings, of Chinese officers, many of whom had to journey merely for the purpose of being painted, their usual place being in the supreme councils. These drawings were sent to France to be engraved, under the direction of C. N. Cockey the younger. They were engraved by various artists, on so large a scale that it was necessary to make paper expressly for them. As soon as they were completed, they were sent to China, where they were only few impressions only being reserved for the royal family of France and for the Parian Library. Helman the engraver made a small copy of them. The originals are not all by Attiret; afterwards, by the Jesuit Castiglione and Sicilier. They are defective in design, and it is evident that the authors have paid too much deference to the taste of the Chinese to satisfy that of the Europeans.

The emperor created Attiret a mandarin, but by his position as a Jesuit it was impossible for him to assume the worldly distinction: he died at Peking in 1768, aged 66. The emperor gave 200 ounces of silver towards the expense of his burial.

(Extrait d'une Lettre du Père Amiot, de Mars 1769, de Pekin, contenant l'édite du Frère Attiret, &c., inserted in the Journal des Savans for June, 1771.)

ATTORNEY. By an act (6 & 7 Vict. c. 73) passed in 1843 the whole of the laws relating to attorneys and solicitors practising in England and Wales were scattered over less than sixty statutes, were consolidated. In the new act special care is taken to prevent unqualified persons practising, and persons seeking to be admitted attorneys are subjected to a regular examination. The control of the profession, which had fluctuated from the period of its origin, when it was held in relief, is now conducted by a board of attorneys, continuing in practice, is confined to the Incorporated Law Society, which is appointed registrar of attorneys and solicitors. The Commissioners of Stamps are not to grant any certificate forinidad, until the attorney's or solicitor's name is written on the stamp paper, or any bearing the same design as that of the stamp, and applying is entitled thereto; and the commissioners are annually to deliver to the registrar all such certificates, with the
ATTRACTION. The possibility mentioned in the article Cornusor, P. C., of bringing under one law both the attraction of gravitation and that of cohesion, has been since reduced to more than a possibility, namely, to a considerable extent, if the law can be actually stated. This remarkable addition to the nascent theory of molecular forces is the work of O. F. Mossotti, and was published in a pamphlet entitled 'Sur les Forces qui régissent la constitution inférieure des corps,' apéros pour servir à la détermination des lois de l'action à distance, par O. F. Mossotti, in 1836, 4to. This paper is translated in Taylor's 'Scientific Memoirs,' vol. i., and Mr. Pratt, in the second edition of his 'Mechanical Philosophy,' observing that Mossotti's theory can be conceived with an ultimate view to complex application, is, for the present, one of the most remarkable cases, has given the mathematical view necessary to include those simple cases and no more, in a perfectly sufficient manner.

The observed facts are, that particles which are very nearly in contact with one another repel each other in a manner which certainly depends, among other things, on the temperature; but that at a certain distance they cease to repel, and begin to attract, each other, and that with considerable force; at a still greater distance that attraction becomes comparatively feeble, and coincides with what is called the attraction of gravitation, varying inversely as the square of the distance. That this attraction of gravitation, and no other (or, at least, a very small one) exists at ordinary sensible distances, is satisfactorily proved by the Cavendish experiment. [Wetson or the Earth, P. C.]

Many hypothetical laws might be constructed which fulfil all these conditions; but the great interest of Mossotti's investigation, and perhaps much of its value, consists in the bearing taken by his analysis of the existing facts, imagined upon grounds with which his views had no necessary connexion, and upon his having given a basis of the utmost simplicity to the numerical law on which he proceeded. This basis is no better than that all molecular attractions and repulsions vary inversely as the squares of the distances.

When Epinus explained Franklin's electrical theory, his hypothesis was that the particles of matter repel one another, and also the particles of the electrical ether, which he supposed to be attached to and existing round each atom of matter. But he supposed the particles of ether to attract the particles of matter; so that of the two species of particles, called matter and ether, each repels the particles of its own kind and attracts those of the other. Epinus even went so far as to suppose that the attraction of gravitation might be a necessary consequence of such a theory, on the supposition that the attraction of the matter and ether was a little greater than the repulsions. So far Mossotti has adopted and accepted his views, but he has shown that Epinus could not have had the least reason to suppose, namely, that attraction of cohesion, the repulsion which takes place when the distance is smaller than that of cohesion, and the attraction of gravitation, which exists at distances too great for cohesion, are all to be found among the consequences of this theory.

If there exist in space molecules of matter which repel each other, in a fluid or ether of which the particles also repel each other, while the particles of the matter attract those of the ether, it is obvious that each of the particles of matter will, by its attraction, collect about it a condensed atmosphere of ether. If the attractions and repulsions be all inversely as the squares of the distances, then Mossotti finds that, in consequence of the atmospheres of ether, two molecules at a distance \( r \) (the attraction of the particles of matter for those of ether being presumed a little, and but a little, greater than the repulsion of the particles of matter from each other) will repel each other with a force represented with great approximation by the formula

\[
\frac{1}{(1+\frac{a}{2})r^2} \cdot \frac{a}{2} \cdot \frac{b}{2},
\]

where \( a, b \) are certain positive constants. To make the results agree with observed facts, \( a \) must be considerable, and \( A \) much greater than \( B \). When the formula is positive, repulsion is represented; when negative, attraction. When \( r \) increases to a very small, the force of the cohesion, or the force of attraction of cohesion, when \( r \) increases to a certain value, it vanishes, and afterwards becomes negative; at the value of \( r \) just mentioned there is stable equilibrium. As \( r \) still increases the attraction increases. At the maximum, a minimum at another certain value of \( r \), and afterwards, if \( a \) be considerable, diminishes as the inverse of
squares of the distance, or in a ratio incommensurably near to it.

All this agrees with the facts of observation, and with the numerical law of the facts as far as we know it; to which it must be added that an increase of the density of the ether would increase the distance at which particles are in equilibrium, which is generally done, indicating that the caloric, are made consequences of one law, which was never done before. This law may or may not be the law of nature; in the latter case it may still be valuable as a suggestion towards a law of nature.

**ATTraction, Electrical.** Under this designation it is intended to notice the apparent attractions and repulsions which take place when bodies are in particular states with respect to electrical power.

From a very early time it was known that amber, when excited by being briskly rubbed, seemed to draw towards it such light bodies as straws and feathers; and the phenomenon, as well as that of an apparent repulsion, is now exhibited in a more striking manner by presenting a cylinder of excised glass or of excited wax to a pit ball suspended by a silk line. [Electricity, P. C., pp. 335-6.]

In attempting to explain by what means these actions might arise, it is imagined that there may exist in all material substances, fluids, which participate in a particular manner one another attractive or repulsive powers, while a mutual attraction may take place between the fluid particles and those of the substance with which they are combined.

The hypothesis of Watson and Plateau was that there exists but one kind of such fluid: it was supposed that, in exciting glass and some other bodies by friction, the fluid was abstracted from the earth through the material by which the friction was produced, and accumulated upon the surface of the body, which thus obtained more than its natural quantity. It was supposed that this excess readily passed into any body near it, provided the latter had less than, or only its natural quantity, or at most had not so great a quantity in proportion to its size as the quantity lost by the glass. In the attraction of resuscious bodies it was supposed that the fluid passes from those bodies, through the material employed in the friction, to the earth; and thus the resuscious bodies were supposed to have less than the natural quantities. Hence arose the distinction between positive and negative, or repulsive and deficient electricity; and the theory of Elinpsus and Cavendish relating to the distribution of electricity on the surfaces of bodies is in conformity with this hypothesis. But the hypothesis is open to some objections: thus, when bodies are combined, it is which, when they are made a part of, the ordinary state, is combined with them, they are observed to repel each other mutually; and it must therefore be inferred that the particles of bodies exercise upon each other a strong repulsive power, a circumstance which is not reconciled with the history of electricity existing among the bodies in nature, or with the cohesive power by which the particles of all bodies are held together. It is moreover impossible to conceive, as Biot observes, that negative or repulsive electricity, that is, an absence of fluid, be developed on the surfaces of bodies according to the hydrostatical laws by which a real fluid would be developed.

To this hypothesis succeeded that which is now generally received. It was proposed about the same time by Symmer in London and by Galvani in Italy, that the whole of the Coefficient of Electricity, or the elasticity of the matter, consists in the assumption of two fluids, of directly opposite qualities, existing at the same time in combination with the particles of all bodies in nature: the particles of each fluid are conceived to exist in every body in strong repulsive force, while the particles of the unlike fluids mutually attract each other. The experiments of Coulomb with the electrical torsion balance have proved that the attractive and repulsive forces vary in intensity inversely as the squares of the distances between the particles, and that equal distances the attractions and repulsions are exactly equal.

The manner in which the mutual actions of electrical particles produce the phenomena of attraction or repulsion in bodies, which are generally done, consisting in the consideration of the effects arising from the decompositions of the natural electricities of the bodies, is conceived to depend in part on the pressure of the atmosphere, and in part on the conducting powers of the bodies. Thus, if by any excitement electrical particles be collected on the surfaces of two bodies (oppose two spheres) which are non-conductors, they will be retained there by the pressure of the surrounding air, and by the impermeability of the material: hence the bodies must take the motions which result from the repulsion or attraction of the fluids on them, according as those fluids are of the same, or of unlike kinds, and of equal or unequal thickness, or are driven in abundance to the opposite side, so as to be more dense, or to form a thicker stratrum there than on the side nearest to the non-conductor. But the reaction of the electrical fluid against the surrounding atmosphere is proportional to the square of the thickness of a stratum, it follows that there is an excess of force tending to make the conducting body recede from the other; and it is easy to perceive that a like explanation may be given of the contrary movement which takes place in the conducting body when the two are charged with unlike kinds of electricity.

The circumstances relating to the distribution of electricity on the surfaces of bodies agreeably to the hypothesis of two fluids, have been determined with the aid of a most refined analysis, by La Place, Ivory, and Poisson; and the 'Theory of Electricity,' in the 'Encyclopedia Metropolitana,' contains an investigation of the distribution on the surfaces of spheres. The results are there computed numerically, and compared with the phenomena; and the discrepancies are found to be only such as may fall within the limits of the unavoidable errors in the experiments themselves.

The hypothesis of electrical fluid, moving in opposite directions, is also adopted in order to explain the phenomena of galvanism and electro-magnetism; that which is considered as positive flowing from the zinc, through the neutralized copper, and thence to the passive magnetized bodies on one another are capable of being explained on the hypothesis of two fluids, the particles of which repel each other according as they are of the same or of unlike kinds, and of equal or unequal thickness; the forces being inversely proportional to the squares of the distances.

The hypothesis of two fluids, moving in opposite directions, is also adopted in order to explain the phenomena of galvanism and electro-magnetism; that which is considered as positive flowing from the zinc, through the neutralized copper, and thence to the passive magnetized bodies on one another are capable of being explained on the hypothesis of two fluids, the particles of which repel each other according as they are of the same or of unlike kinds, and of equal or unequal thickness; the forces being inversely proportional to the squares of the distances.

ATTHEM, P. C.] The negative current. may be understood to be revolving at the same time in like manner, but in a contrary direction. The currents thus revolving are supposed to set on the particles of the magnetised needle, disposing them to arrange themselves parallel to its axis, and so as to bring the latter in the position of a tangent to the curve described by the fluid about the wire.

The hypothesis of Ampère differs from that which has been generally adopted since having formed the conducting wire into two parts which could be so connected with the opposite poles of a galvanic battery that the current of positive electricity might be made to pass along the two parts in the same direction; the two wires being placed side by side, in the former case, the wires (which were deliberately suspended in horizontal and parallel positions) seemed to attract, and in the other case to repel one another. He from thence inferred that the fluids passed in rectilinear directions, or parallel to the axes of the wires, and that the particles were attracted, as is the case with two magnets, when the poles of opposite sign are placed near each other, and that the phenomena observed in the former theory were in reality effects of the general law of attraction and repulsion among the particles of matter.

It has been ascertained that the current of electricity produced by the electrical machine causes deviations in a magnetised iron or brass organ, when it is placed on a table, of the same direction as that of a magnetic needle, that the effect produced on the needle is the same as that which was before described for, as the planes of the revolving currents are supposed to be perpendicular to the axis of the magnetised body, that axis must and does itself in the direction of a tangent to a circle supposed to be perpendicular to the axis of the conducting wire of the battery.

The negative current, it is observed, has been produced by means of the galvanic battery, and by the action of the electric, galvanic, and magnetic fluids, if such there be, are identical. An experiment made by Mr. Faraday, in which a magnetised needle caused to float on water was found to enter a glass tube having its axis on a level with the surface and about which a galvanic conducting wire was spirally wound; while such magnetised needle would not enter the bore of a hollow magnet placed in the same situation as the glass tube—seemed however to show that the nature of the galvanic and magnetic fluids, which church has been hereafter to be published; but it is to be hoped, both for the sake of the author and of the public, that his representative will not allow such undeniable proofs of his father's genius—compositions which will add so much to the resources of our clergy—remain sterile particles of obscurity.

ATTRACTION OF BALLS. [WEIGHT OF THE EARTH, P. C.]

ATTRACTION OF MOUNTAINS. [Attraction, P. C.]

ATTRACTIONS, ELECTIVE. This name is given to those tendencies by which the particles of bodies unite, or combine together, to form other bodies; and, as these tendencies exist in different degrees between the particles of different bodies, the name is intended to denote an approximate choice of the particles of one kind in preference to those of another kind. [Affinity, P. C.]

ATWOOD, THOMAS, a composer of great eminence, eminent for the production of compositions, by the Dublin chamber, and the theatre, was born in 1765, and commenced his professional education, as one of the 'children of the Chapel Royal,' under Dr. Nares, and his successor, Dr. Ayrs. On the change of his voice, and consequent retirement from the king's service, he intended abroad, by and by the expense of his patron, the Prince of Wales, for the purpose of completing his studies in the schools of Italy. He first went to Naples, where he continued two years, receiving some instruction from the regio director of the royal theatre, the chief maestro, one of the episcopal favourites of the last age. But the discerning young student, seeing that the musical art was rapidly on the decline in the country where it had flourished so long, and that it was renovated and full vigour in Germany and Italy, and immediately returned to London, and entered the pupil of Mozart, with whom he formed an intimacy which led to a daily intercourse, and to the importing not only the usual information, but also a knowledge of those deeper recesses of the art which seldom, if ever, is, or can be, communicated in the course of ordinary lessons. This happy result is manifest in all Attwood's compositions, the best of which are by the great master, who said—according the report of Michael Kelly, the singer—'Attwood partakes more of my style than any pupil ever had.' (Kelly's Reminiscences.)

Soon after, the young Englishman's return to his native country, he was engaged by his majesty, at the suggestion of a number of illustrious pianists, an appointment however which he soon relinquished, his friends not thinking it altogether compatible with the station he was entitled to hold. On the arrival of the Duchesses of St. Albans, who were his musical predecessors; and on the ill-fated marriage of the Prince of Wales (afterwards George IV.), he was constant in his attendance on the princess, to whom he gave almost daily lessons. In the conscientious performance of this duty, which he continued to perform after it became impossible for him to travel, he instructed many pupils. One of these, a young man, at the time his illustrious pupil would not be displeasing in another quarter, he gave offence to his patron, who, for several years after, made his resentment felt.

In 1795 the dean and chapter of St. Paul's elected Mr. Attwood as organist of that cathedral, and in the following year, on the death of Dr. Dupuis, he was appointed composer to the Chapels-Royal. For the solemnity of the coronation of George IV., he was required officially to compose an anthem. The king was pleased with the composition of a work which has since been heard and admired in all parts of the kingdom, as a proof of the skill of his organist, Mr. Attwood. He was appointed to his prominent place, in the uppermost gallery, at the chapel service, and was received with the received with the usual honours.

Mr. Attwood's compositions are so numerous, as to be in the class before named, that we can only say, generally, that a more than usual proportion of them are likely to reach distant proximity. His cathedral works, which unite the elegance of the modern school with the becoming sobriety and dignity of the old, have been performed with one and all; but it is to be hoped, both for the sake of the author and of the public, that his representative will not allow such undeniable proofs of his father's genius—compositions which will add so much to the resources of our clergy—remain sterile particles of obscurity.

AUDIAN, or AUDEANS, a sect of heretics, so called from their founder Audius, or Audeus, who is said to have been a native of Messerenia, and who lived in the first century. Having begun, as usual with religious reformers, by attacking the manners of the clergy, and perhaps also the government of the church, he proceeded in this fine till he was expelled from the body of the faithful; upon which he resumed the episcopal see, and was hereupon immediately banished by the emperor Constantine to Scythia. This is stated to have been about the year 338. Among various erroneous opinions and practices attributed to Audius and his followers of Easter, he is also accounted the author of the practice of allowing the Jews, the admission of all descriptions of persons indiscriminately to the Lord's Supper, the doctrine of the eternity of fire, water, and darkness, and especially that of anthropomorphism, or the resemblance of the Deity to the human form. This last heresy, in particular, as a Christian article of faith, appears to have originated with Audius, spread extensively. 'The pilgrim Cassian,' Gibbon writes, 'who visited Egypt in the beginning of the fifth century, observes and imitates the reign of anthropomorphism after the usage of the Jews, the admission of all descriptions of persons indiscriminately to the Lord's Supper, the doctrine of the eternity of fire, water, and darkness, and especially that of anthropomorphism, or the resemblance of the Deity to the human form.' (Dec. and F. of Rom. Emp., chap. 47, note.) But we have no account of the tenets of Audius, either from himself or any of his followers. For we are not informed for all we know of him upon the statements of the orthodox writers and the writers of that and the next age, Athenæus, Augustine, Ephyrius, and Theodoret. He is admitted to have been a

X 2
person of learning, and Epiphanius acknowledges that in his exile he exerted himself with great success in converting the barbarians.

AUGMENTATION, COURT OF. This was a court established by 27 Hen. VIII. c. 27, for managing the revenues and possessions of all monasteries under 200l. a year, which by an act of the same session had been given to the king's prerogative and determined to remain incorporeal. The revenues under that sum were to be called ' the Court of the Augmentations of the Revenues of the King's Crown,' and was to be a court of record with one great seal and one privy seal. The officers of the court were, a chancellor, who had the great seal, a treasurer, a king's attorney and a king's advocate, all ten men and 8s., seven receivers, with clerk, usher, &c. The oaths of the different officers are given in § 4 of the act. All the dissolved monasteries under the above value, except those preserved in the act for the use of the university and the survey of the court, and the chancellor of the court was directed to make a yearly report of their revenues to the king. The annual revenue of 376 monasteries under 200l. a year, which were suppressed, was 52,000l. and the value of their goods, chattels, plate, &c. was estimated at 100,000l.

The records of the Court of Augmentation are now at the Augmentation-Office in Palace-Yard, Westminster, and may be searched on payment of a fee.

CHRISTIAN JOHANN WILHELM, a celebrated German theologian, was born on the 27th of October, 1771, at Eschenberge, a village near Gotha, where his father was pastor. After receiving his preparatory education in the gymnasium of Gotha, in 1790 he entered the university of Jena, under the late illustrious devotus himself, theology and philology. After the completion of his studies several years passed before he obtained an appointment, but although he had to struggle with great difficulties in gaining a livelihood, he still continued his studies with great activity; he began his literary career by contributions to theological journals, and at length in 1798 he resolved upon entering on the career of an academical teacher at Jena. In 1800 he was made professor of Oriental literature, and in 1808 he succeeded Ittig, in the chair of Oriental literature, which he held until his death in 1807, on that of theology. The popularity of his lectures and the many valuable works which he published during his residence at Jena, not only induced the Duke of Saxe-Weimar to make him a member of his consistory, but other German universities made great efforts to draw him from Jena. In 1811 however he accepted the chair of theology in the university of Breslau, to which he was invited by the Prussian government, and in addition to which he was honoured with a seat in the consistory of the state of Silesia, of which he had hitherto chiefly distinguished himself as a writer upon theology and ecclesiastical matters, had now ample opportunities for displaying the practical character of his mind. His influence upon the progress of the church in Silesia and upon the education of his pupils was very great. At the time when the French marched into Russia, Augusti was rector of the university, and it was owing to his intrepidity and patriotic spirit that the property of the university was preserved. His conduct was severely censured by the tildos, and those who would have yielded to the enemy, but the cullumous reports which had been spread about him were soon shown in their true light, and the Prussian government acknowledged its gratitude to him by various honourable distinctions. In 1818 Augusti was honoured with the chief professorship of theology in the newly established university of Bonn, and with the title of Councillor of the Consistory at Cologne. The influence which he had by the Protestant Church in the Rhine province of Prussia rapidly increased, and in 1833 he was placed at the head of the ecclesiastical affairs of that province, by being appointed director of the consistory of Coblenz. Notwithstanding the numerous duties which this office devolved upon him, he still continued his literary labours. In 1833 he died, while his death was deplored by the Khristische Literaturzeitung, and several persons, among whom were M. Wilms and M. Becker, met at his death. M. Becker may be considered an orthodox Lutheran. His writings, most of which are of an historical or archaeological nature, are very useful as works of reference; but they are deficient in elegance and simplicity of form, and contain no evidence of learning and industry than of the true spirit of an historical writer. The following list contains the most important of his works: — 1 , Exegetisches Handbuch der Geschichte der älteren Religionsvölker. 2 , A continuation of Berger's Praktische Einleitungen in das Alte Testament, 3 , Apologien und Parallelen Theologischen Inhalts, 4 , Beiträge zur Geschichte des Reichs, 5 , Die Kirchenordnung des Philippus, 6 , Leipzig, 1806, 8vo., 5 , Historisch-Kritische Einleitungen ins Alte Testament, 7 , Leipzig, 1806, 8vo., 6 , System der christlichen Dogmatik nach dem Lehrbegriff der christlichen Kirche, Leipzig, 1805; 7 , Denkwürdigkeiten berühmter Christen, Breslau, 1787-55, 8 , Jena, 1857. The Augmentations Office has been most important of all Augusti's works; he subsequently condensed it into a Manual of Christian Archaeology, 9 , Endbuch der Christlichen Archaeologie, 3 vols. 8vo. Leipzig, 1830-57. 10 , General and Historical and Ecclesiastical History of the ancient Eastern churches, 11 , Leipzig, 1832, 8vo., 10 , Historische Ecclesiastischen Epitome, Leipzig, 1834, 8vo.; 11 , Entwürfe zur Christlichen Kunstdenkmäler und Litteratur. 0 , this work only one volume, was published when Augusti died. (Jenaische Altorientalische Literatur-Verzeichniss.)

AULA'CODON. [CLELODES, P. C. S.] AUL's, a fossil genus of Polyplacophora, Aulopraxis, from the Silurian strata.

AURELIUS, CELIUS. [CELIUS AURELIUS F. C. S.]

AUST CLIFF. In the bone-bed of this famous locality, usually classed with the lias formation, occur a few euripus remains which appear to belong also to the keuper deposits. This has been thought sufficient reason for removing the bone beds out of the lias. But if we regard their minoetrical and geological relation, this displacement will hardly be allowed.

AUSTEN, WILLIAM, an English metal-founder of the fifteenth century, and the contemporary of Donatello and Ghiberti, the most renowned of his foreign rivals. A very interesting document respecting Austen and other artists has been preserved by Sir William Dugdale in his 'Warwickshire.' Austen had a great share in the construction of the celebrated tomb at Warwick, in St. Mary's church, of Richard de Beauchamp, earl of Warwick, who died in 1459. In the document in question, which is the covenant between the earl's executors and the artists to be employed in the construction of the tomb, he says: ' AUSTEN, citizen and founder of London, xvi. Martii 20 H. 6, covanant, &c. to cast, work, and perfectly to make... of the finest latten (brass) to be gilded that may be found, in such figures emboased, of lords and ladies in divers manneres, called weepers, to stand in hounours about the tomb, those images to be made in breadth, length, and thickness, &c. to xiv. patterns made of timber. Also he shall make xxvii. xxvi. lease images of angels, to stand in other housings, shall be appointed by patterns, wherefore ix. for one side, and ix. after another. Also he must make an heare to stand on the tombe above and about the principal image that shall be in the tombe according to a pattern; the stude and workmanship to the repairing to be at the charge of the executors. And the executioner shall be bound to make an image that shall lye on the tombe, of the weepers so made in laette, xxvii. iv. d. And for every image of angels so made &c. And for every pound of latten that shall be in the heap. And shall also pay the costs of the said Austen for setting the said images and heare.'

'The said William Austen, xi. Feb. 28 H. 6, doth covenant to cast and make as image of a man armed, of fine lattin, garnished with divers patterns; a man with a griffon with a garter, with a helmet and crest under his head, and at his feet a bear musted (muzzled), and a griffon perfectly made of the finest latten, according to patterns; all of which to be brought to Warwick and layd on the tombe, and shall repair and ayse the said images, or any part thereof for the image, perfectly made and layd, and all the ornaments in good order, besides the cost of the said workmen to Warwick, and working there to lay the image, and besides the
cost of the carriages, all which are to be born by the said executors, in total £137.

In the opinion of Flaxman, these works of Aiken are equal to what was done in the same time, and though he is acknowledged only as the founder, he may be termed the great designer of the figures, as the patterns spoken of in the covenant may have been made in relation to size and costume, and not as exact models to prepare the casts from. The pay of 1s. 6d. for the free copies of the models, was fixed at that time the price of an ox. The tomb itself cost 1,250l., the figure of the Earl 40l., and there was an additional expense of 10l. for gilding. The whole expense of the tomb and the chapel, called Beausite, to the Chapel, was 945l. 4s. 7d. The other artists employed in this design were—John Essex, marbler; Thomas Stevency, cooper-smith; John Bourde, of Corfe Castle, marbler; Bartholomew Landspring, Dutch goldsmith, of London; John Frudie, of Westmeader, citizen and stayner of London; and Kristian Coleburne, also a painter or stainer of London. The monument, one of the earliest and best in England, is still in a state of preservation, and is of brass; the meaning therefore of the word latten, which has been disputed, is, apparently brass. (Dugdale, Antiquities of Warwickshire, p. 446.)

AUSTEN, JANE, was born December 16, 1775, at Steventon in Hampshire, of which place her father was rector. Mr. Austen was a man of liberal education, and high acquirements, and he bestowed upon Jane an education superior to what was then general among females of her rank in society. But if education did much for her, nature did more, creating the beauty of mind and person, with sweetness of disposition and sensibility, and desirable engagingness of manner. During the latter years of Mr. Austen's life she resided chiefly at Bath, but after his decease his widow and her two daughters retired to Southamnton, where they continued till May 15, 1817, and afterwards to the village of Chawton, where Jane wrote her novels. There they remained until her declining health rendered it desirable that they should remove to Winchester for the sake of nursing and economy. She died July 34 of that year, and was buried in the cathedral.

Of her six novels, four were published in her lifetime, but unanimously—"Sence and Sensibality;" "Pride and Prejudice;" "Mansfield Park;" and "Emma." The two others, "Northanger Abbey," and "Persuasion," did not appear until the year after her death—an extraordinary circumstance as regards the former, that being her first production, and having besides been actually disposed of to a publisher, who nevertheless, in a letter much noticed, makes allusion to the domestic class—are all of them delineations of every-day life and actual society, entirely free from that professional conventionality as to characters and incidents which gives a certain artificial quality to nearly all productions of the kind. In spite of this, and the denominated of her being the foremost rank of that species of fiction, they exhibit extraordinary graphic power and truthfulness, and reality without exaggeration. Nor is it their least merit that they are all of them works of artists, of great and painted tendency, without any praise of moralizing. They have all been translated into French by Madame de Montolieu and others.

AUSTRALIA, SOUTH. (South Australia, P. C. S.)

AVANZI, Jacopo di Paolo D', a celebrated old Italian painter of the fourteenth and fifteenth century; he lived at Bologna, but whether he was a Venetian or a Bolognese is doubtful.

There was an ancient noble family of Bologna of the name of Avanzi, of which Jacopo may have been a member, but there were of the same name of Jacopo di Paolo, who may have been the father of Jacopo. This was Maestro Paolo, the oldest known painter of that city. In the sacristy of the Piacentine there is a painting by him with the following inscription—"1386, Paolo de Venetia pintit hoc opus;" however, Maestro Paolo may have been the master of Jacopo, as it was not an uncommon practice in the earlier centuries for painters to sign simply their Christian names followed by that of their master or father upon their works, as is the case sometimes with the signs of cutaneous diseases, and the same omission is urged himself "Jacobsus de Avantis." Franco Bolognese and Vitale dalle Madonne are both said to have been his masters, but without the slightest countenance. Jacopo was himself sometimes called Dalle Madonne, and Vitale, painted at one time almost exclusively Madonnas.

Jacopo is generally mentioned in company with Simone da Bologna, or Simone de' Crocifissi, or Crocifissi, as he was called, for the same reason that Jacopo was called Dalle Madonne. They became partners, and each painted a part of their joint productions, a circumstance which has led to theayer of treating of Simone separately. But it would have been, in the present instance, that the figure of the tomb was not Avanzi, but Benvenuti, according to the manuscript of Orelli.

Most of Jacopo's works have perished, but some remain. He painted the tomb of San Francesco da Padua, in the church of Sant' Antonio at Padua, which was long attributed to Giotto, but painted by Jacopo in 1376. He painted also, in partnership with Simone, many frescoes in the old church of the Madonna di Mozzaratta, without the Porta San Matteo, at Bologna, which were much praised by Michelangelo and the Caracci, considering their period. Besides which he painted two triumphs in a public ball at Verona, and some works in company with Aldighieri da Zevio in the chapel of San Giorgio in the church of Sant' Antonio at Padua. The former were considered works of extraordinary merit by Mantegna; the latter have been lately recovered from dirt and oblivion by Dr. E. Förster, one of the editors of the Kunstkamb. They were described by him in that journal, pp. 18 and 22, of the year 1838. Jacopo died probably in the early part of the fifteenth century. There are two pictures attributed to him in the gallery of Bologna. (Vasari, Vita de' Pittori, &c., and the Notes to Schom's German Text of Vasari, Miscellanea Uffizii, Storia Pictoria, &c.; Giolandi, Piscicatoce della Bologna.)

AVE—Medical Properties of: Several varieties, chiefly of the species A. sativa, are cultivated in Britain, particularly the north of England and lowlands of Scotland, though on the west and north-west coast of Scotland it is found that this kind of hemp is near the limit of the kingdom. The climate of Scotland is peculiarly suitable to the profitable cultivation of this plant, which flourishes where wheat and even barley languish (Oakes, P. C., vol. xvi. p. 881), while the constitution of the seed renders it a suitable article of diet for the inhabitants of that country. The seeds, which are official, are at once delineal and medicinal. The fruits or grains consist of the skin or husk, which is inclosed by machinery, and the seeds, which, when coarsely ground, form the wild-colt of Scotland. This inclosed seed in various of the different varieties, and in different seasons and localities. Vogel, who is commonly followed on this point, gives the amount at 66 meal and 34 bran or husks; but under proper culture, it is often as high as 78 meal and only 22 of husk per cent. (Bousingsault, Rural Economy, translated by G. Law, p. 229.) The meal or farina consists (per cent.) of starch 59 (sometimes as high as 728, Dr. Christison), 1075 procachus nutructions, 43 of albumen, 2 ossea, the mass, 24 ligneous fibre and moisture. The seeds, or derived of husks, or decoricated (gratum), are employed under the name of groats or gits to form with water the Decoctum Aveae, or water-gruel. When bruised, ready for use, they form the wild-colt of Scotland. This in small quantities and moderate doses may be used in a pint of water, according to the object in view. When employed for an article of nourishment, the gruel may be used thick; when the nostrum is designed for more severe perturbation at the commencement of a cold, it should be thin; and the addition of butter, spices, and wine, or anything save a little salt and sugar, is to be avoided. This is regarded as a light and digestible article for invalids. With some, it naturally produces hearburn and thirst: the same objection is urged against oatmeal, whether eaten in the form of oat-cakes, or employed to form porridge, the usual breakfast of the labouring classes, and of the children of the middle classes in this country. This is inflammable, and may be very dangerous if not properly boiled. It is certainly true; but as a national fare, nothing could be found more fitting. It gives a warmth and support to the system, far superior to wheaten bread, and therefore most proper for a cold and damp climate. The Derbyshire miners, from choice, prefer it to all other breakfast articles. This plan of nourishment appears to me to enable them to support their strength and perform their labour better. (Sir Joseph Banks, in Davy's Agricultural Chemistry, 5th ed. p. 145.) The idea that oatmeal is the proper food in all diseases has in a large measure foundation (Cullen's Materia Medica, vol. i. p. 279.) The husks are frequently steeped in water for a few days, and then drained off. The liquid when boiled stiffs into a dish called aowsen in Scotland. This is slightly acid, and forms with milk a most nutritious food of great utility. The husks are esteemed as a most suitable article of diet in summer, in a climate where, for a short period the heat is intense.
When oats are used as food for horses, it is very advantageous to steep them in water for two or three days, till they sprout or spire; the saccharine matter is thereby developed, and the grain becomes nutritious and digestible.

**AVERTMENT.** *Pleading, P. C.*

**AVES (Fossil).** Fossil birds have been recognised by Mr. Hitchcock in the red clay of Connecticut (Hitchcock), in the Wealden of Sussex (Mantell), in the chalk of Maidstone (Owen), in the tertiary beds of England and France (Curvier), in the bone-caves of Kirkdale (Buckland), and in many late deposits. From New Zealand comes the Diornis of Owen.

**AVICENNA, a genus of plants belonging to the natural order Myoporaceae.** The calyx is 5-parted, persistent, the segments erect, subovate, obtuse, concave; the corolla monopetalous, 2-lipped, upper lip square, emarginate, flat, lower limb, with ovate, equal, flat divisions, tube bell-shaped, short; the stamens 4, didymous; ovary 2-celled; style, subulate, erect, length of stamens; the stigma bifid, acute, the lower division bent down; the seed single, large, albuminous. The species are natives of New Holland and America.

A. *tomentosa*, White Mangrove, has coriace, ovate leaves, tomentose beneath. It puts forth twigs from the stem, resembling those of the common mangrove. The bark is found in New Zealand, and is used in commerce.

**A. resinafera** is a native of New Zealand, and is said by Forster to yield a green resinous substance that is eaten by the New Zealanders as food. It is remarkable also for its clusters of resinous globes, of a nature similar to that of the *A. aurita*.

**AXINUS (Sowerby), a fossil genus of Conchifera, of which some species occur in the magneisian limestones, and one in the London clay.** To those which are found in the magneisian and other palaeozoic limestones, Mr. King applies the title of *Schizodes*, P. C. S.

**AXIS, in Botany, a term that is applied to the root and stem of the whole plant.** The result of placing the seed of a plant in a place fitted for its growth, is the development of the embryo. The plumule ascends into the air, whilst the radicle descends towards the earth. The former is said to be the *ascending axis* of the plant, the latter the *descending axis*. It is around these axes of growth that all other parts of the plant are arranged. Those which are found upon the ascending axis, or stem, are collectively termed the *appendages of the axis*, and individually constitute the scales, leaves, bracts, fruits, flowers, and modifications of those parts of the plant; all these parts are in connection with the vascular system of the axis, and must not be confounded with mere expansions of the epidermis and the like, such as ramenta, tendrils, &c., which are no real connections with the axis.

The cause of the direction taken by the ascending and descending axis of plants has been variously explained. This is evidently a complicated question, and one which involves the great mass of facts in the organization of plants, and probably animals, which determine their peculiar forms, habits, and movements. Dutrochet, who has lately written on this subject, and who is quoted by Lindley in his 'Introduction to Botany,' says:—"The downward direction of the roots may be understood: it may be said that, like all other bodies, they have a tendency towards the centre of the earth, in consequence of the known laws of gravity (as is the opinion of Knight in 'Phil. Trans.' for 1806); but on what principle then is to be explained the upward tendency of the stem, which is by means of the expansion of its leaves and here lies the difficulty. Dodart is the first who appears to have paid attention to this circumstance; he pretends to explain the turning backwards of seeds sown in an inverted position, by the gravity of the earth. It is probable that the root is composed of parts that contrast by humidity; and that the stem, on the contrary, contracts by dryness. For this reason, according to him, it ought to happen, that when a seed is sown in an inverted position, the radicle will turn back towards the soil, while the part of the humus on which the contrary, turns to the sky, or rather atmosphere, a drier medium than the earth. The experiments of De Hamel are well known, in which he attempted to force a radicle up-wards and a plumule downwards by enclosing them in tubes which prevented the turning back of these parts. It was found that the radicle and plumule, in the natural direction, they became twisted spirally. These experiments, while they prove that the opposite tendencies of the radicle and the plumule cannot be altered, still leave us an ignorance of the cause of such tendencies. The well-known fact of the stems of plants growing upright in the dark places, has led De Candolle and other observers to attribute the tendency of the stem to an upward growth to the influence of light. Another well-known fact, that of the tendency of plants growing in the shade, is the cause of its growing upwards. He found by experiments the Mirabilis jalapa and other plants, that although roots lay in general no tendency towards the light, yet such a disposition does become manifest provided the terminal shoot of a root becomes slightly green, as occasionally happens. It found that the ends of the roots of Mirabilis jalapa became occasionally coloured, and, on placing the plants in damp ground, he found these roots had a tendency to come to the series towards the light. This is also supposed to be the cause of less stems of such plants as Sagittaria sagittifolia are known to assume the directions of roots. In this plant shoots are produced from the axilla of all the radical leaves which grow at the base of the water, their growth is directed towards the sky, like those of all vegetables. To young stems which are produced by these shoots are entirely colourless, like roots; and instead of taking a direction towards the sky, as coloured stems would do, they tend downwards, retreating towards the centre of the earth. The tornament next stem takes a horizontal course, and does not assume any tendency towards the sky until the plants become green."

H. von Kielmeyer gave a report on the direction of the organs of plants, to the assembly of naturalists at Stuttgart, in 1835, in which he explained the upward and downward growth of the axis of plants by the theory of polarity. He supposes that there is acting upon plants a principle the analogy of magnetism and electricity, which, polarizing the cells of which a plant is composed, give to one set an upward and to another a downward growth. Although every writer on the subject has endeavoured to give to one agent the position of a cause in this phenomenon, it will be found on inquiry that the particular directions of the stems of plants can no more be referred to one cause, than the growth in particular direction of the organs of animals. Growth, in whatever direction, is the result of all the forces that are acting on an individual organism, as the changes of position, temperature, light, the chemical constitution of the tissues, and electrical agency are all involved in producing the determination of the particular direction of the roots and stems of plants.

**AYLiffe, John, LL.D., an English jurist, of the circumstances of whose life hardly anything is known.** He left behind him in his works substantial monuments of his industry and learning. He styles himself Fellow of New College, Oxford. In 1714 he published in 2 vols. 8vo. 'The Laws of Powers and Pawns as they are used in the Romans,' &c. In 1722 he published 'A work of which a great portion is avowedly an abridgment of Wood's 'Athenae.' In 1726 he published in folio 'Paragon Juris Canonicorum Anglaurum, or a Supplement to the Canon and Constitutions of the Church of England,' in which he brings much learning and learning; against the exercise of a separate and independent legislative power by ecclesiastical bodies. In 1732 he published 'The Laws of Wills and Powers as it was in Use among the Romans;' and in 1734, 'A Law-Book of the Royal and Municipal Laws of Rome, as it was established in that Empire,' &c. This volume covers the greater part of the author's subject, but the complete work was never published. Ayliffe's books give an explanation of those scientific terms of reference to the Cure of justice which often puzzle casual readers of the foreign civilians.

BABER, or rather BABBER, is an island of the Indian Archipelago, and sometimes included in the Moluccas; but it must properly be included in the large group which is called the Tenasserim Islands. Babber lies between 7° 49' and 8° 11' lat. and is traversed by 190° E. long. According to Kolf's chart it may be about 20 miles long and 10 miles wide. It is surrounded by several smaller islands, of which the largest is Wetang, which lies west of it; and between Babber and Wetang it lies from 14 to 160 fathoms. The island is mountainous, but it does not rise to a great elevation, except towards the extremity, where a summit rises to a considerable height. The interior of the island is uninhabited, except on the western and eastern shores, where there are several small settlements. They constitute two independent communities, which are continually at war with one another; and the principal object of their military incursions is to kidnap young persons, who are sold as slaves to the vessels that visit the island, or obliged to cultivate the fields for their captors. The greater part of the land is still covered with trees and bushes; but the remainder is cultivated, and produces several kinds of roots, Indian corn, and plantsains. There are also considerable plantations of cocoa-nuts and sago-trees. The principal animals are cattle, buffaloes, and goats. Fowls and birds are numerous, especially several kinds of pigeons. Fish is also plentiful, but the natives do not turn it to account. The inhabitants belong to the Malay race, and resemble in their manners, dress, and food the inhabitants of the neigh-
bordering islands, to which they occasionally visit the neighbouring islands; but it does not appear that they have any regular exchange of commodities with them. There come every year to Babber one or two country vessels from Bandia, which import small pieces of cotton-cloth, and export a few slaves and some provisions. When the Dutch spread over the Indian Archipelago, they had a small establishment on this island; but they abandoned it after some time, and it does not appear that the inhabitants have had any dealings with them to-day. The Dutch government has again opened some communication with them. (Kolf, Reise door den weinig bekenden zuidelijken Molu-
schena Archipel).

BABIROUSSA, or BABYROUSSA. [Sudee, P. C.]

BA'BRIUS (Βαβυρίους). Since the publication of the article BA'BRIUS in the P. C. a considerable number of his fables have been discovered and published. Among the numerous MSS. which M. Miniope Minas found in the convents of Greece, there was one containing the choliambic fables of Babrius, which was found in the convent of St. Laura on Mount Athos. He took a copy of it (the price which the monks asked for the original being too exorbitant) and brought it with the rest of his treasures to Paris in 1842. M. Villainé entrusted the office of editing the fables to M. J. F. Boisnade, and the work appeared towards the end of 1844 in one octavo volume. The Greek fables which were thus rescued are now before the world, but are not however the complete collection which Babrius made. Their number is 128; they are arranged in alphabetical order, that is, according to the initial letters of the fables, and the present collection does not go further down than the letter Β, and therefore contains only five fables. The fables are arranged in sections, and each of them is preceded by a preface and a proem. The preface in which the poet Babrius lived, and which was formerly believed to have been the last century before the Christian era, is at present more doubtful than ever, on account of certain allusions which occur in the fables. M. Boisnade, who believes that Babrius was a Roman, has not entered upon the question of the Babrius; but he has written a monograph upon the subject. Boisnade has added a critical commentary and a Latin translation: the title is Babriou Moêlîâon, 1 Babríi Fabûle Iâmbiques CXXII., nunc primum editi. J. F. Boisnade recensuit, Latine ex recensione editus, CXL. (Classical Museum, part vi. p. 412, &c.)

BABYLONIA (Βαβλωνία), the territory so named from the city of Babylon on the Euphrates. [BABYLON, P. C.]

It was considered by the ancient geographers as a part of Assyria; but its boundaries cannot be fixed. The physical character of the Babylonian Plain is described in the articles BABDAY (Pashahic) and TIGRIS, P. C.

BACHELOR, an unmarried man. The legislation of the Romans placed the unmarried (casulæ) under certain disabilities, the chief of which were contained in the Lex Julia et Papia Poppea. The original Lex was simply called Julia, and was passed n.c. 18. (Dion Cassius, liv. 16.) The Lex Papia et Poppea, which was intended as an amendment and supplement to the Lex Julia, was passed a.D. 9; and both these laws seem to have been considered as one, and they are often referred to under the title of the Lex Julia et Papia Poppea. One object of the Lex was to encourage marriage. An unmarried person (casu-
le), who was in other respects qualified to take a legacy, was incapacitated by this Lex, unless he or she married within one hundred days. (Ulpian, Frag. xvii. 1.) The law was the same, whether the whole property (hereditum) was left to a casule. (Gaius, ii. 111, 144, 368.) It was the opinion of the lawyers, that though a casule could not take directly under a testament, a casule could take by way of fidei commissum, or trust; but the Senatus-consultum Pegusianum, which was passed in the time of Vespasian, rendered a casule equally incapable of taking anything by way of fidei commissum. (Gaius, ii. 286.) A testamentary gift, which failed to take effect because the heir or legatee was a casule, was called Caducum (and the word was applied to other cases in which the possessor of a thing was equally incapable of taking anything by testamentary gift) than the Senatus-consultum Pegusianum, which was placed in the time of Tiberius, extended the penalties to unmarried persons of both sexes who were above sixty and fifty years old respectively, and it made them for ever subject to the incapacities. However, a Senatus-consultum Claudianum, passed in the time of Claudius, mitigated the severity of the Priniciamus, in case a man married above the age of sixty, provided he married a woman under fifty, for the Roman law considered a woman under fifty as still capable of procreation. (Ulpian, Frag. xvi.; Suetonius, Claudius, c. 28.) An unmarried man who had attained the age of twenty-five was also allowed to take on orbi, that is, married persons who had no children from the age of twenty-five to sixty for a man, and twenty to fifty for a woman. Childless persons who came within the terms of the Lex lost one-half of any hereditas or legacy; and what they could not take became Caduceum. The Lex also gave direct advantages to persons who had children. The original object of this Roman law was perhaps only to encourage marriage, but it was afterwards used as a means of raising revenue. In the preceding exposition of the Lex Julia et Papia Poppea, it has been assumed that the provisions above enumerated applied both to males and females. The word casuleb, indeed, seems to be applied only to males, and the Latin term for an unmarried woman is Vidua, which means any woman who has not been a husband. But the expression of "married" is not very common in the law. "Qui intrà sexagesimum vel quæ innaquinquagenísum annum neulli legi (the Julia, or Papia Poppea) parens," &c., shows that the provisions applied both to males and females. The phrase "married" is not absolute, but the phrase would be "qui Quaeve," &c. That the Lex applied to women also, appears from other evidence. (Cod. viii. t. 57.) Under the republic there were also penalties on celibacy, and legal inducements to marriage, which are mentioned in the laws of Cato the Elder, Plautus, and Juvenal. The Lex Julia and Claudianum were intended to check the marriage of Augustus. Julius Caesar, in the division of the Campanian lands, gave allotments only to those who had three children or more. (Dion Cass. xlvii. 7; Appian, Bell. Civ. ii. 10.) These concerns are also laid to the

VOL. I-
have had the power of imposing a penalty called Access Uxorium, "wife-money," on men who were unmarried. (Festus v. 
"Uxorium.") It was a tax payable by the priests of the Roman and Bactrian religion, and by the Romans, in order to encourage the propagation of children; the object of the English law imposing extraordinary payments on bachelors, and relieving to a certain extent married persons with children, was apparently to raise money, though a certain vague notion that marriage was encouraged seems to have been held to the tax. The law-maker. A constitution of Constantine (Cod. viii. 
tit. 58) relieved both unmarried men and women from the penalties imposed on caelisili and orbi, and placed them on the same footing as married persons. This change was made 

in favor of the heretics, many of whom abstained from marriage for religious motives.

Not only bachelors, but widowers have been unequally taxed in this country, and there is more than one instance, which were enacted in the 18th century, in which bachelors have been favored by special exemptions, or have been charged less on account of the number of their children. In 1695 an act was passed (6 & 7 Will. III. c. 6) entitled "An Act for granting to his Majesty certain rates and duties upon marriages, births, and burials, and upon bachelors and widowers, for the term of five years, for carrying on the war against France with vigour." Bachelors above the age of twenty-five, and widowers without children, paid 1s. yearly, and further according to their rank. Therefore, being no duke the tax was charged on the 3rd, 4th, and other ranks. The provision was charged on the 3rd, 4th, and other ranks. The provision was made by William Pitt. In 1765, when Mr. Pitt proposed a tax on female servants, he exempted persons who kept only one servant, and who had two or more lawful children. Certain children under the age of 14 living in the house with them. But to make up for the deficiency, he proposed that the tax on servants should be higher for bachelors than for others; and he stated that the idea of this tax was borrowed from Mr. Fox. This differential rate has not been continued to the present day, and the number of servants charged at the higher rate in 1843 was 11,851, or rather more than one-tenth of the whole number charged. Roman Catholic diocesans are exempt from additional duty. When the income-tax was imposed by Mr. Pitt, in 1798, deductions were allowed on account of children, and an abatement was made of 5 per cent. to a person with children, when the income was above 60l. and under 400l.; and other rates of abatement were allowed according to the amount of the term and the number of children; the present law extended to incomes of 6000l. a year and upwards.

There does not appear to be a tax on bachelors in any country in Europe. In the city of Frankfurt an income-tax is imposed on persons who work in the city, "if they are foreigners, and not married."

BACILLARIA, a large family of Infusorial animalcula, constituted by Ehrenberg, who includes in it upwards of thirty genera. The siliceous shields of these animalcula are amongst the most numerous of the forms of Microscoria in the cretaceous, tertiary, and suprapermian. Xanthidia occur in the chalk and its included nodules of flint: Galloto- neae, Navicula, Actinoecyli, Coscinodiscii, Gomphonemia, and other genera, abound in the tertiary marls of Greece, Italy, Bohemia, England, and North America. The siliceous beds of Bohemia (Poliarschier), which are fourteen feet in thickness, contain innumerable shields of Navicula, and probably few of the superficial lacustrine deposits of Europe are which few occur in these beds. No one supposed that the first type was made of glass in any quantity, as are to be sold by the measure and for little more than their intrinsic value. This is actually the case now in some places in India and Afghanistan, though with little effect on the prices of the plants that are cultivated. The late Colonel Tod made a collection of plants during his long residence in India, of which several are of high interest for the botanist. A description of them was given with engravings in the first volume of the Transactions of the Royal Botanic Society of Edinburg, vol. 2, p. 283. The plants are Agap- todotis and of Menander, both Bactrian plants. Their hys- torical value, says Wilson, is undiminished, but nothing of great importance was discovered in these two volumes. The remarkable diminution of their value as objects of rarity within the last twelve years. Instead of only two medals, the cabinets of Paris and London now possess nearly two thousand of it.
coins of Manendar and Apollodorus, of silver and copper, of a great variety of types, and mostly in excellent preservation. The country on both sides of the Indus and north of the Hindu-Koosh has been explored with a view of searching for Bactrian sites. General Ch. de Vigneron, Aïard, and Court, Dr. Swayne, James Prinsep, Sir Alexander Burnes, Masson, and many others, mostly British residents in India, have made collections of Bactrian coins, which enabled him to construct a complete series of Bactrian kings, of Greek and barbaric descent.

Under the term Bactrian coins are understood in this article only such medals as were struck by kings of either Greek or barbaric descent who ruled over the ancient kingdom of Bactria or parts of it; but barbaric coins of Mohammedan princes who reigned at Kabul and other places in Afghanistan. The Greek coins may be divided, with respect to their inscriptions, into pure Greek and bilingual coins. The Greek types, such as, Thadostes I., Thadostes II., Euthydemes, Demetrius, and Eucratides, who ascended the throne in n.c. 181, and perhaps reigned as long as n.c. 165. Of Thadostes I. two coins are known. One, a gold medal, was bought at the fair of Nishni-Novgorod in Russia, and is now in the Royal Cabinet of Paris. It corresponds in weight and style with the gold coins of Antiochus II., and the portrait bears so close a resemblance to that of Antiochus, that it is supposed the artist copied the head from a portrait of him on some gold coin of the same time.

The reverse has a naked figure of Jupiter erect, with his back to the spectator, and turned to the left; he is in the act of hurling his thunderbolt from his right arm raised, whilst his left arm extended bears the sceptre; on one side, in the field of the obverse, is an olive branch, and on the other a sheaf of wheat.

The legend on each margin of the reverse is ΒΑΣΙΛΕΩΣ ΔΑΙΜΟΝΙΩΝ ΤΩΝ ΡΩΜΑΙΩΝ ΠΑΤΡΩΝ, perfectly distinct. The second coin is a silver tetradrachm, presented by Sir Alexander Burnes to the British Museum, where there are also many coins belonging to the other Greek kings of Bactria. The bilingual class consists of coins with Helioetes, who reigned about n.c. 147, but bilingual inscriptions are also found on the square copper coins of his predecessor Eucratides. The two languages are Greek and Pehlevi, of which the latter is represented by two characters, forming the Arian or Arianian alphabet. The oldest bilingual coins are all square, the barbaric inscriptions having been adopted together with the barbaric shape, but the later coins are both square and round. Fourteen kings with Greek names are ascribed to this class, the last of whom is Pantaleon, who reigned about n.c. 120. The Greek letters on these coins are naval-headed; the design is generally good, on some very fine, and probably done by Greek artists; but there are also many of very inferior political and artistic character. The circumstance of Eastern emblems of royalty, and different Indian animals and other figures, betrays the decline of Greek civilization. Among the animals, the elephant and the elephant's head, which we find on the coins of Demetrius, Manendar, Apollodorus, and others, is particularly striking. The bull, the bulls' and the rams' horns, the coins of Philexenos, Diomedes, and several other kings, are supposed to indicate dominion in India. The wild horse however and the double-humped camel are believed to have exclusive reference to Bactria. Barbaric dynasties reigned over Bactria from the end of the second century before Christ.

The coins struck by them are bilingual, and betray the decline of art and prevalence of Eastern influence. To this class belong the coins of several kings of the Aramaic dynasty, such as Vemakes, Vandusk, and others. These coins seem to have been independent of the Aramaeidae in Parthia. These coins are rare, and they are bilingual.

Only two Bactrian gold coins are known, one of Diodotus and one of Euthydemes; all the others we know of are of silver, of billon, or of copper.

As early as the beginning of our era parts of Bactria were conquered by princes of Scythian (probably Turkish) descent, whose seats were at Kabul and Jalalabad, and who were finally subdued byander his wife with her family, by the Persian princes, who were exclusively of gold and silver, and bilingual—a proof that Greek civilization, although on its decline, had still some influence upon the people, as was the case in Parthia many centuries before. These were also many coins found in Afghanistan; a fact by no means extraordinary, as the power of the Sassanians in Persia extended occasionally as far as the Indus, so that those Scythian kings were not always independent, but paid tribute to the Persians. The prince of Ikardsa, in the upper valley of the Indus, pretends to be descended from Alexander. As the Greek power in Bactria was maintained in some parts of the Hindu-Koosh after the Scythian conquest, the princely residence of Ikardsa may be a remnant of the Bactro-Greek empire, and a closer investigation into the history of Ikardsa and the whole upper valley of the Indus would perhaps lead to interesting results.

The obscurity prevailing in the history and chronology of Bactria has of course an influence upon Bactrian numismatics, and makes it next to impossible to see the principal writers on these subjects at variance on most essential points. [AFGHANISTAN, P. C. S.]

(Wilson, Ariane Antiqua; Lassen, Zur Geschichte der Griechischen und Indo-Skythischen Königre in Bactria, &c.; Grotfeud, Geschichte der geschichtlichen Parthischen, und Indo-Skythischen Königre von Bactrien, &c.; H. T. Prinsep, Note on the Historical Results deductible from recent Discoveries in Afghanistan.)

BADALCHOW, an Italian painter and engraver, born at Parma towards the close of the sixteenth century. He was the pupil for and some time the assistant of Annibal Carracci at Rome. He was highly raised by Annibal as a draughtsman, who confessed that he surpassed himself; but in painting he was much inferior to Guido or Domenichino.

His engravings are not numerous: the most celebrated are the so-called Bible of Raphael, which he executed in company with Lanfranc, and dedicated to Annibal Carracci; and the four sets of Greek coins which he engraved. Among the most celebrated engravings the best was Galatea, in the Vereosi palace at Rome; a San Francesco at the Capucins of Parma, was also one of his best works; but like his friend Lanfranc, says Lanzi, he always did less than he was capable of doing. The date of his death is not known. [Lanzi, Storia Pittorica, &c.; Malvasia, Felsina Pittorica; Bartch, Le Peintre-Graveur.]

BAGGESEN, Jens, a writer of considerable distinction both in Danish and German literature, was born at Corona in the island of Zealand, February 16, 1764, and was educated at the University of Copenhagen. From his earliest youth he displayed unusual liveliness of imagination, of which, together with satirical humour, his first production, at the age of twenty, gave due evidence; and he obtained a most favourable reception from the public. Yet he himself says that he had no taste for the comic; that in writing his tales he consulted that of the public far more than his own. And that he published them for the purpose of paying off his father's debts and assisting the family: from which it would appear that they were left in embarrased circumstances. Still he seems to have been for some time afterwards without fixed pursuit of any kind, except that of writing some of his best and the only popular books of a Danish character. He had however acquired the favour of the Prince of Holstein-Augustenburg, who bestowed on him a small pension. In 1789 he visited Pyrmont in hope of benefiting from the waters, and meeting there with his friend Count Molcke, gave promise of doing an invalid service. He accompanied him to Switzerland, and returned home through France and Germany. Of this journey he has given a full narrative, or rather picture, in his 'Labyrinthen,' one of the most interesting of his works, it being, as he himself calls it, his 'Dichtervorleser,' or 'Wanderings of a Poet,' in which he records his varied feelings, opinions, and contemplations, and portrays his own character. For that period of his life to which it refers, it may in fact be considered a piece of autobiography, and it certainly enters at some length into one rather important circumstance of his personal acquaintance—his acquaintance with Sophia Haller, the granddaughter of the poet, whom he married at Berne, in March, 1790, after which he immediately returned to Denmark. Notwithstanding his attachment to his native land, he did not remain there long: he fancied it a sphere too contracted for him, felt unsettled and unable to apply to anything seriously, so set out again for Germany, taking with him his wife, his son, and his cousin, VERY. He then visited Paris, being at that time an ardent enthusiast for the French Revolution, and there he became acquainted with many of the public characters of the day. On his second return to Copenhagen he visited the then new city of Berlin, but found it too irksome for his disposition, and as change of climate was thought necessary for his wife's health, he set out the following year for Germany, but lost his wife at Kiel. Instead of returning, he proceeded to England, where he married his two young children; and in 1798 again visited Paris, where he married Sanna Reibus. This planless mode of life
BAGLIONE, GIOVANNI, a Roman freeco and oil painter of the seventeenth century, at present better known for his "Lives" of his contemporaries than for his paintings, though in his time he enjoyed the highest patronage. He was born at Rome about 1673, and was for a short time the pupil of a Florentine painter, Francesco Morelli. He attracted the notice of the popes Sixtus V. and Paul V., the latter of whom created B. a Cavalier del Altino di C. In 1618 he was elected Prince of the Academy of St. Luke. The date of his death is not known; he was still living in 1642. He executed a great many works in Rome, some at Naples, and some at Florence, but he painted very little, and his works are rarely seen in collections; he excelled in colour, and in light and shade. One of his best works is the Resurrection of Tabitha, in St. Peter's at Rome.

His book of memoirs, of which he has written 81, is written in an extremely simple style, without the slightest attempt at criticism, and if he ever ventures upon a qualifying remark, it is sure to be one of commendation. G. B. Passari published an edition of it at Naples in 1738, with the addition of the Life of Salvador Ross; there is also a memoir of B. in Sigismondo, which contains a long list of his works. The following is the title of the book—Le Vite de' Pittori, Scultori, Architetti, ed Intagliatori, dal Pontificato di Gregorio XIII. nel 1572 fino a tempi di Papa Urbano VIII. nel 1642.' The edition appeared at Rome in 1642, and a second appeared in 1649, according to Orlandi.

BAGLIONI, an historical family of Perugia in Italy, which in the middle ages produced many distinguished warriors, and was esteemed powerful over many native towns. Perugia was in those times one of the most populous and important cities of central Italy, and governed itself as a municipal community, under the nominal protection first of the Emperors and afterwards of the Popes. Like most other Italian cities, she distrusted a strong church and the nobles, and that of the people. The Baglioni belonged to the nobles. We find in the twelfth century Ludovico Baglioni appointed Imperial Vicear of Perugia, by the emperor Frederick I., who in his will, made his grandson, Count of Orvieto, head of the house, and successor of the male line of the Baglioni.

After the fall of the Sabinian dynasty, the nobles and the popular party had frequent conflicts with alternate success. In the year 1393 a general outbreak took place, when Pandolfo and Pellino Baglioni, with seventy other patricians, were killed in flight in the streets, and their alternates being left as ruffian poemen, the city remained in possession of the town, until 1416, when Braccio Fortebraccio, as the head of the nobles, re-entered the town by force, and proclaimed Lord of Perugia. Malatesta Baglioni, son of Pandolfo Baglioni, had succeeded in the possession of the town, when Braccio died in 1416, but his uncle, Pandolfo Baglioni, was appointed General of the Holy See by Pope Callixtus III. He defeated Francesco Sforza near Lodi in 1433, and took Lord of Spello by Stius IV., and died in 1474. His wife, Margaret of Mantua, died in 1480. He was succeeded in the kingdom of Naples by his son, Francesco, who, however, did not live very long, but returned in 1414 once more to Copenhagen, where he was warmly received, yet soon embroiled himself in a violent feud with Oehlenschlager, whom he opposed as the bearer of the race of poetry. He led him to make Paris once more his place of residence, with occasional visits however to Copenhagen. On his health beginning to decline, he went, in 1425, to Carlsbad for the benefit of the waters, and was returning thence to Copenhagen, when he died at Hamburg, October 3, 1426. After his death, in the same year, appeared his 'Adam and Eve,' a most extraordinary subject for a 'humorous epic,' not less so for being chosen by one who had told the public that there is no relief for the human spirit, which he nevertheless indulged when on the verge of the grave. The warm-heartedness and enthusiasm of his youth must have been exchanged for a very different temper of mind before he could have brought himself even to the contemplation of such tremendous subjects, and his famous 'Philosophia,' his Klopstock must have evaporated altogether. He is said to have left in manuscript a poem of similar and even stronger character, of which Faust was the hero. His correspondence with Reinhold and Jacob, in two volumes 8vo, was published by his sons in 1833; and a complete edition, in twelve volumes, of his 'Danske Verker,' comprising all his Danish poems and other writings in that language, his translation of Holberg's 'Nels Klim' inclusive, was published by his sons and C. A. J. in 1827-32. A well-executed portrait of him is prefixed to it.
Hungarian wars against the Turks. He afterwards served Charles V. in Italy and on the coast of Tunis; and he rose high in the favour of Pope Paul III., who restored to him his paternal estates. Lastly he entered into the service the republic of Venice as a private soldier, in several important situations. He was governor of Famagosta in the island of Cyprus when the Turks besieged the place in 1670. After a long and brave defence he was obliged to capitulate, in August, 1571, on terms of capitulation, which were somewhat severe. But Mustapha Pasha, disregarding the capitulation, caused Baglioli and the other Venetian officers to be beheaded, except Bragadino, who was fayed alive by order of the Pasha. Several of the individuals of the family of Baglioli distinguished themselves in the Italian wars of the fifteenth and sixteenth centuries.

(Crispolti, Perugia Augusto; Sansovino, Della Origine e dei Fatti delle Famiglie Illustri d'Italia; Vernaghioli, Vita et Imago Militari di Malatesta Baglioli, Rome, 1839; Fabretti, Biografia dei Capitani Venturieri dell' Umbria, Montepulciano, 1840.)

BAGSHOT SAND. One of the higher members of the tertiary group of England is thus designated. It has been investigated by Mr. Warburton. (Geol. Trans.)

BAI]. [F. C., vol. iii. p. 287.] The general principles of the Law of Bail remain unchanged. But as, since the statute 1 & 2 Vict. c. 110, § 5, all personal actions are to be commenced within six years, the periods of the peace, important and other situations in which the right of bail may be held in civil causes are now confined to those which are specified in the third section of that statute. It is thereby enacted that if a plaintiff in any action in any of the superior courts of law in Westminster, in which the defendant is sued, is satisfied of the evidence of a judge of one of the said courts that such plaintiff has a cause of action against such defendant or defendants to the amount of 20l. or upwards, or has sustained damage to that amount, and there is probable cause for believing that the defendant or any one or more of the defendants is or are about to quit England, unless he or they be forthwith apprehended, such judge may order the defendant or defendants be held to bail in any sum he may think fit, not exceeding his or their own personal estate, or damage done, or liable to be done, if they may thereafter sue out a writ of capias, and arrest the defendant, or, when so arrested, to remain in custody till he shall have given a bail bond to the sheriff, or shall have made deposit of the sum endorsed on such writ of capias, together with 10l. for the costs, according to the present practice. All subsequent steps of the proceeding are to be conducted according to the present forms. The power given by the statute to a judge, to grant an order to hold bail, is not affected by the sections 7 & 8 Vict. c. 50 (Lord Drougham's Act). With regard to criminal law, the statute 7 Geo. IV. c. 64, has been somewhat altered by the 5 & 6 Will. IV. c. 35, § 3, which, in Rothe's, Montefiore's, and Argyle's cases, if they shall think fit (of whom or one or other shall have signed the warrant of commitment), may admit any person or persons charged with felony, or against whom any warrant of commitment for felony is signed, to bail, in such sums and with such sureties as they shall think fit; notwithstanding such person or persons shall have confessed the matter laid to his or their charge, or notwithstanding such justices shall not think that such charge is groundless, or shall think that the circumstances are such as to raise a presumptive of guilt.

BAILLIE, ROBERT, was born in Glasgow, April 30, 1602. His father, Thomas Baillie, is described as a citizen of Glasgow, and was a younger son of the family of Baillie of Jerviston, a small property near the town of Lanark. Baillie married his cousin, Mary Lanarkhair (not to be confounded, as it has often been, with the family of Baillie of Jerviswood, in the same county, the head of which, in the latter part of the seventeenth century, was the eminent Presbyterian patriot Robert Baillie, who, after a long confinement in prison and suffering, was executed at Edinburgh in 1684). The subject of the present notice was educated first at the grammar-school and afterwards at the university of Glasgow, at which he was entered a student in March, 1618. He entered in 1620, and probably in 1629 or 1634 he entered into holy orders; in August, 1626, he was admitted to the office of one of the masters or regents (as the professors were then styled) of the college; and this situation he held till the year 1631, when he was ordained and consecrated rector of Kilwinning in Ayrshire. At this time Baillie's sentiments on the subject of church government were extremely moderate; his ordination was ecumenical, and he was attached on principle, as well as by education and habit, to that form of polity, which was indeed at this time the established civilisation system in France. Charles I. made his attempt in 1626 and 1637 to impose the tridentine rite upon the French canons upon the Scottish church [Sportwood, John, P. C., p. 379]. Baillie was induced to attend a meeting of the Supplicants, as the opponents of the obnoxious measures called the General Assembly held at Edinburgh in November, 1637, and October, 1637; and this proved the turning point of his life. He was probably far less zealous upon the subject of ceremonies and forms than any other person present; but he had studied the civil controversy, and was adopting antinomian views upon other points which then divided the English church, and, having been prevailed upon to explain the reasons upon which he confessed, although in mild terms, that he disproved of the new service-book, he spoke at some length, and so delighted the clergy and people present with the opinions avowed by Laud and his party, the authors of the book, that he was urged to send the substance of his speech forthwith to the press, and from this time he took his place as one of the chief managers and leaders of the Presbyterian and anti-court party. When he first rose to speak at the Edinburgh meeting, it, he tells us, 'with some piece of blushing, in such an auditory,' the like whereof he had never before addressed; but he adds that he was heard with great applause, and on evening was a famous man all the town.

He still however retained something of his original moderation when he made his appearance, as one of the members for the presbytery of Ayr, at the celebratory assembly held at Glasgow on the 21st of November, 1638; and so much so, that he stood alone in refusing to concur in the vote declaring episcopacy to have been always abjured by the Scottish church: he proposed that it should be declared to be removed now, but never before abjured. The prevailing party however were aware of his value, and he was soon entirely gained over. When arms were taken up, he appeared in the camp at Dunse Low, in the beginning of June, 1639, in qualitity presbyter and assembly of the general in the west; and tells us, as the fashion was, a sword, and a couple of Dutch pistols at his saddle—though he intended, he says, to fight no man unless he should encounter a robber by the way. A pacification was in fact arranged at Berwick (on the 15th of June) before any blood was shed.

In April, 1640, Baillie published what may be considered to have been an extension of his speech at the meeting of Supplicants, in a large quarto pamphlet at Edinburgh, under the title of 'A Reverend Wooster: or, An Evident Demonstration of the aforesaid Arminianism, Popery, and Tyranny of that faction, by their own confessions,' &c. In the following October, when the Scotch had again taken arms, he proceeded, on the invitation of the Earl of Argyll, to Newcastle, taking with him a number of copies of his book; and here he was nominated one of the four clerical commissioners who were deputed, with nine laymen, to proceed to London, under the protection of the great seal, as negotiators to a treaty with the king. He reached London on the 16th of November, and remained there till the beginning of June, 1641, having, during his residence, witnessed the trial of Strafford and other remarkable occurrences, of which his letters contain very detailed and graphic accounts. Some of his letters written during Strafford's trial, he writes, in a somewhat sanguine as well as sanguinary strain, 'When we get his head, then all things will run on smooth.' In June, 1642, Baillie was appointed to one of the joint universitaries of the University of Glasgow; but immediately after this he was again dispatched to England as one of the five clerical commissioners from the General Assembly to the Westminster Assembly of Divines. He reached London on the 10th of October of this year; and in the next three years: he did not leave till the 6th of January, 1645. He was sent back again before the end of March, when, as he was proceeding by sea, the ship was driven towards the coast of Holland, and Baillie and some of his companions endeavoured to run up to the Moray firth—when Baillie an opportunity of spending a few days at Middelbourg and Rotterdam. He remained in London on this his last visit till December, 1646, employing every moment that was not taken up in attending the Assembly, in reading, and in keeping in close and friendly intercourse in Scotland and elsewhere. He now resumed his duties as Professor of Divinity—continuing also, however, to take an
active part in public proceedings. After the execution of the king, he was one of two clergymen sent over to the Hague, in March, 1640, with the commissioners of the Scottish estates (or Parliament) to enter into negotiations with Charles II. Upon this mission he was absent till July, and during that interval he composed and published at Delft an answer to a pamphlet against Presbyterianism by Bishop Brumhall, under the title of 'A Review of Doctor Brumball, late Bishop of London.' In 1641 he was engaged in another Delft writing, 'A Writ to the Dutch Westindies.' When Cromwell advanced upon Glasgow, in October, 1650, after the battle of Dunbar, Baillie fled to the Isle of Cumnay with Lady Montgomery, but left, he tells us, all his family and property in the care of a relative. His courtesy was great; for he took such a course with his soldiers that they did less displeasure at Glasgow, nor [than] if they had been at London, though Mr. Zachary Boyd railed on them all to their very face in the High Church. Under the new government he was engaged in writing a Method of Divinity on the removal of his colleague to a chair at Edinburgh; but he was after this greatly disquieted by the promotion to offices in the University of various persons who went much farther than he was disposed to go in compliance with the times. In church politics Baillie now allied himself with the more moderate party, or those who were called the Resolutioners (that is, the supporters of certain resolutions passed at an Assembly held at Perth, in December, 1650), in opposition to those called the Remonstrants or Protestors. One of his great vexations was the appointment of Patrick Gillespie, one of the leaders of the latter party, as Principal of the university in 1653; but immediately after the Revolution that office was turned over to Mr. Baillie himself. He was now promoted to his office in January, 1661. He did not however long enjoy this preferment, having died about the end of August in the following year. He had been twice married, and had eight children, of whom only one was by his second wife.

Of Baillie's works the most important, besides those already mentioned, are his 'Disuasive from the Errors of the Time,' 4to. Lond. 1645; his 'Anabaptism, the True Fountain of Independency,' Antwerp, 1650; his 'Second Part of the Disuasive,' 4to. Lond. 1647; his 'Appendix Practica ad Joannis Buxtorffii Epitomen Grammaticae Hebraeae,' 8vo. Edin. 1653; and his 'Operis Historiae et Chronologic Liuthri Duci,' folio, Amst. 1653, and Basle, 1669. He also published several sermons and other short books. But all of the produce of his pen by far the most interesting part consists of his Letters, written to various friends, and especially to his relation, the Rev. Mr. William Spang, minister of the church at Edinburgh, who was one of the English congregation at Middelburg in Zeeland, which extend, with considerable interruptions, from 1637 to within a few months of the writer's death, and are to be ranked among the most valuable memorials of that important period of our national history. The letters were written by him mainly to the wife of Mr. Spang, to whom he was married, and to his own family and friends, and the transcript thus formed is now among the records of the Scottish church. Other transcripts, more or less perfect, also exist—the most valuable of which is one, in four vols. 8vo., made for the use of Baillie's family, and now in the possession of the Rev. Thomas M'Curie, of Edinburgh. An edition of them appeared at Edinburgh, in 1775, in 2 vols. 8vo., under the title of 'Letters and Journals written by the deceased Mr. Robert Baillie, Principal of the University of Glasgow; carefully transcribed by Robert Aiken' (supposed to have been schoolmaster at Anderton). This publication is said to have been undertaken on the recommendation of Dr. Robertson and Mr. Hume. It was originally published in 4to. for the Banlatyme Club, and the 8vo. impression, for the Edinburgh Society, afterwards taken off by over-running the lines. It is in all respects a very carefully edited book.

BALLY, FRANCIS, the best friend of astronomy among the English nation, and one of the most distinguished of its promoters, will be biographically known to posterity by a valuable memoir, read by Sir John Herschel to the Astronomical Society, in November, 1844. From this memoir, and the writer's personal knowledge of Mr. Bally, the following account is drawn up.

He was born April 28, 1774, at Newbury in Berkshire; his father was a banker at that place. He had, of course, a liberal education, and is said to have shown an interest in pursuits of physical science at an early age; his attachment to these branches of knowledge was afterwards increased by the circumstance of living in or near London, where his father's business was his own choice, and he accordingly served his time in the city of London. He then changed his views, and after travelling for about two years (1798-90) in the United States and the West Indies, he returned to London, and, in company with his father, he went into business as a stockbroker, being taken into partnership by his father's friend, Mr. Whitmore; this was before 1805, and probably not long after his return from America. He soon began to be known to the public, and became so eminent in his business as afterwards in his scientific pursuits. In 1806 he wrote a pamphlet in defence of the stockbrokers against the city of London, and in 1814, he was appointed by the Committee of the Stock Exchange to get up the evidence against the perpetration of the celebrated fraud of De Berenger (better known in connexion with the name of Lord Cockrange), which he is said to have done in so masterly a manner that no more complete chain of evidence was ever offered to a court of justice. He published two reports on the subject, and another on the distribution of the money stopped.

It is the peculiar part of Mr. Bally's history, that while actively engaged in business, in which he accumulated a large fortune, he spent much of his time in promoting the various objects of his mind. He first published his 'Tables for the purchasing and renewing of Leases' (1802, 1807, 1812, 8vo.); next the 'Doctrine of Interest and Annuities,' (1806, 4to.); then the 'Doctrine of Annuities' (1807, 8vo.), revised with the aid of the 'Appendix to the doctrine of Life Annuities and Assurances' (1813, 8vo.). Also, 'An Account of the several Life Assurance Companies' (1810, 1811, 8vo.), which is an extract from the work on life assurance. The book on leases was very useful; that on interest was accompanied by a reprint of the best tables (those of Smart), and was the most complete exposition of the subject which had been given. The work on life annuities (translated into French by Dr. C. 1818) was much sought after, and was exceedingly useful; it was the first in which a rule was systematically applied in a modern and symmetrical form to the whole of the subject; the first in which tables of greater vitality were allowed to compete with the North-american tables; and the first in which the fundamental principles of the subject (not so complete as the subsequent one of Mr. Milne) was made to represent cases of annuities, &c. by a distinct notation. The appendix arose out of the refusal of the Royal Society to print the book on the local Taxation. The method of calculating annuities proposed by Mr. Barrett. (Revisions, P. C.)

This method, which is now very extensively adopted, and will, beyond a doubt, supersed all others, would probably have been lost if Mr. Bally had not thus preserved and given it to the world; in doing which he made some justly severe remarks on the Society which had thus endangered a capital improvement in commercial mathematics. The whole work used to sell for four and five times its original price when it became a second-hand book. The book is now published nothing but the writings already enumerated, he might still have been cited as a remarkable instance of active and useful exertion during the hours of relaxation from a laborious occupation.

It was Mr. Bally's habit so methodically to commit to writing all he learned, that he made enables him to publish the 'Epitome of Universal History,' 2 vols. 8vo. 1813, a short account of the political changes of the world with dates attached, and valuable chronological tables at the end. He had previously (1812) published a 'Chart of History' with a complete table of dates, and an explanation of the scale of Pierre Charles Belidor, but cannot here minutely describe. In these researches he marked the unsettled date of the eclipse of Thales, and made the calculations and wrote the paper in the Philosophical Transactions of the year 1776. He was also engaged as the first astronomical paper, and previously to his retirement from business he had published in the Philosophical Magazine and
elsewhere a number of small tracts calling attention to dif-
ferent points of astronomical interest as they arose.

The observations as made in 1843, and those afterwards
left his chambers in Grey's Inn for a detached house which
he had bought, No. 37, Tavistock Place, which will always be
remarkable as the building in which the repetition of the
Cavendish experiment was performed. From this time till his
death, he wrote without all of his energy of his character
in the promotion of astronomy. Between the ages of fifty-
one and seventy, when most men in his circumstances
would have been enjoying the leisure to which commercial
men usually look forward, he contrived to make the catalogue
so as to add to his name of a lifetime. We can here only note a few heads, referring
the reader for a full list of his writings, and for further details,
to the memoir already cited.

He was (in 1820) one of the founders of the Astronomical
Society, whose name will always be as much for the promotion of its
science as any one ever did in its first quarter of a century;
and that so much can be said is mainly due to Mr. Baily, whose
attention to its affairs was as constant and minute as if it had been a
firm of which he was the chief clerk, with expectation of
being taken into partnership. 'Of his management of our
society,' says Mr. Sheepeahns, 'it is difficult to speak so as
to convey a correct idea. No assumption, no interference with
other people, no maritain spirit (which seems almost natural to all
men), was ever manifested by him; his memory was perfectly
and correctly, and without bustle. He hit, better than any chair-
man I have ever seen, the mean between strictness and laxity,
and while he kept everything going in its proper channel, he also
had the tact to give to every one who wished to do anything
useful, and his equal readiness to supply every deficiency and
to do the work of everybody else. He was also the person
who never was asleep and never forgot anything, and who
contrived, by his good humour, hospitality, and good sense, to
keep everything in train.'

He was one of those who exerted themselves to produce a
reformation and enlargement of the Nautical Almanac, and
whose efforts did at last prevail upon the government to place
it upon its present distinguished footing.

In pendulum experiments [Pendulum, P. C.] he was among the foremost of those who investigated the newly
observed effects of the air upon the instrument. When the
expedition which set out under Captain Foster returned with
the loss of its able commander, Mr. Baily reduced and digested his
observations, which take up the whole of the seventh volume of the Astronomical Society's Memoirs.

He superintended the formation of the same society's standard
scale, and wrote a full and valuable account (Ann. Astron.
Soc. vol. i.) of the history and present state of the subject,
with a catalogue, intended, to be transformed, on the
occasion of a committee-room of the House of Commons, the government
scale, of which that of the society is a copy, being under the
charge of the Speaker. As it happened, Mr. Baily's unac-
maining habit of writing the last and revision of this,
this copy; had the work lasted a few months more, as it
would have done in most hands, the copy would have been
destroyed with the original in the fire at the Houses of Par-
lament in 1834.

Of the repetition of the Cavendish experiment we have spoken elsewhere. [Weight of the Earth, P. C.] Had
that article not been written during his lifetime, we should have
said much more on the determined honesty with which the experiments were conducted and the cause of the observed
divergence of electricity detected. A very large number of hours
which have every reason to suppose undetected when it is
called twelve hundred, was spent in the mere act of watching the
movements of the torsion pendulum. The account of this
experiment forms volume xiv. of the Memoirs of the Astrono-
mical Society.

The Astronomical Society's catalogue of stars was the sug-
gestion of Mr. Baily and Mr. Gompertz, and was superin-
tended by the latter. Old star lists had been granted consent as to the method of reducing the stars. Sir
John Herschel says that this catalogue 'put the astronomical
world in possession of a power which may be said without
exaggeration to have changed the face of sidereal
astronomy.'

Of the remarkable circumstances attending the publication of
Mr. Baily's Life of Flamsteed (4to, 1835, with supplement in
1837) we have spoken elsewhere. [Flamsteed, P. C.]

To this work was annexed a new edition of Flamsteed's
catalogue, with such a complete examination of the original
material as has never been attempted. Mr. Baily, who knew Mr. Baily well can have any idea of the confidence
with which such an examination made by him is to be treated.
He had already revised Mayer's and Lacaille's catalogues in the
Astronomical Society's memoirs, volumes iv. and v.

Mr. Baily put the new work to hand in his catalogue in the 13th volume of the Memoirs of the Astronomical
Society, which is entirely his own work, and printed at his
own expense. It is the third complete volume (individually
published) of Flamsteed's catalogue, and is associated with about fifteen memoirs inserted in other volumes, almost
all the annual reports, and various addresses, notices, &c.
It contains a new edition of Ptolemy's catalogue in Greek, with
those of Ulugh Beigh, Tycho Brahe, Halley, and Hevelius.
Mr. Baily was not a professor scholar, but he had quite know-
ledge enough to do for Ptolemy more than any other scholar
could have done. An astronomer might have restored Ptolemy's
catalogue to what it ought to have been; a scholar might
have made a judicious collation of existing editions: but
the former alone would in many cases have undeniably
sacrificed the probable text to astronomical correctness; and
the latter would have let pass many instances in which a
correct text can be divested of astronomical impossibility and
restored, and perhaps probability, to what is now a mere
requisite, and experience, combined with methodical habit,
had given him extraordinary resources. It will be long, we
suspect, before the old catalogues can be properly cited from
any other writer.

He suggested to the British Association the republication of the immense catalogue of Lalande, called the Histoire
Celeste, combined with that of Lacaille; the two together
containing fifty-seven thousand stars. He suggested to the
same body the extension of the Astronomical Society's cata-
logue to ten thousand stars, accompanied by the coefficients
of reduction. He superintended the construction of these tables
and a portion of the printing, and he left the-preface to the
latter completely written. He had also undertaken the con-
struction of the new standard scale, wanted by the govern-
ment in consequence of the destruction of the old one.

This is a brief account of Mr. Baily's principal works; we
cannot enter upon one of the ninety heads under which all his writings, great and small, are given in the Memoir
cited.

In June, 1841, while crossing Wellington Street, a man
riding furiously to carry the news of some public event to an
evening paper, threw him down, and he received a severe
wound in the head. After lying for more than a fortnight in
the greatest danger, he slowly recovered, and began to apply
himself to the Cavendish experiment as usual. In the spring
of 1844 an affection of the kidneys came on (not, it is sup-
posed, of any duration), and he died on the 26th of August, 1844.
His last public appearance was at Oxford, on the 2nd of July, to
which place he went with some difficulty to receive the honorary degree of Doctor of Civil Law. He
was never married.

'To term Mr. Baily,' says Sir John Herschel, 'a man of
brilliant genius or great invention, would in effect be doing
him wrong. His talents were great, but rather solid and
sober than brilliant, and such as seized their subject rather than
with a tenacious grasp than with a sudden pounce.'

This sentence, read as it was to an assembly which had had long
experience of the qualities of his subject, was better under-
stood than it can be by those who were not acquainted with
him. He was in fact the reverse of that; a man who
knew not, and it is not easy to give a precise description
of that which distinguished him from other men. Again, his
biographer describes him as possessing 'a calm the reverse of
apathy, a moderation having nothing in common with indif-
ference, a method diametrically opposed to the rude
natural test.' This sentence will look as if it had been written for the sake of the points;
and yet there is an absolute truth about it which would have been sacrificed if it had simply been said that Mr.
Baily was calm, and that he spent his life in a monastic
mire which we have cited had been read, it being, his readers, well
as they thought they had known their deceased president, were
astonished to find how much they had underestimated the
enormous amount and collective value of his labours, until the mass
was placed before them; they could not do much for the items, but
had never rightly formed the sum total.

Mr. Baily's knowledge of his subject was great, and he
never began to carry a plan into execution until he had sedu-

BAI 167 BAI
lovely examined his own views and those of others. His judgment was sound, and he really exercised it; he was one of the few men who ask advice to get the means of coming to a decision. But there was in his habits of execution something very methodical; we seem right to say that in this respect he was a genius of an uncommon order. Many persons thought he learnt this power in business; we are perfectly satisfied that he carried it to the Stock Exchange, and would have had it whatever walk of life he might have been through. Even when he was in research, as that required by his Life of Flamel, he was never to be found at a table loaded with materials for reference. To have painted his portrait as literary men are sometimes represented, near a mass of folios and manuscripts, would have spoiled the likeness: there should have been a pen, a paper, a book. When engaged in discussion with his astronomical friends in his own house, which generally required the production of some fresh volume every ten minutes, the books fell into their places again almost of their own accord, and without any apparent interruption of the conversation. These little things were perfect emblems of the manner in which he arranged his studies: his mind was as ready for use as his bookcase. He was not distinguished, as far as we ever knew, for having a great variety of occupation, seldom worked in an evening, and he was very much in society. Nevertheless his share of any work was always done before that of any one else. But with all this manner of proceeding that any able and required counsel, there was a suspension of operations without effort; and he could repeat the subject again and again, in private thought and discussion with his friends, from week to week and from month to month, as if he had been one of those slow and deliberative spirits who never do anything, but because they can never make up their minds precisely how it is to be done. In our opinion this was the greatest secret of his reputation: namely, that he could at pleasure, as occasion required, execute his judgment, or deliberate much and more certainly. It is no exaggeration to say that he did, in the last twenty years of his life, much more and better work than younger men of much greater original power have done in twice the time. And besides this, the admirable personal qualities to which we have already alluded, and which made it so easy to cooperate with him, led to his being able to make others do more than they could have done without him. His high moral worth added to his power; and all these together made him the greatest historian and father of the natural world. He had, we suspect, a strong love of fame, though perfectly free from vanity; but the same judgment which marked his selection of other things appeared in his choice of means to secure a lasting reputation. That he has won it is certain: the history or the natural world is complete without an account of his labours. Those who are well acquainted with Delambre's history of the science will easily imagine how much that severe judge would have abased of his vigour, had the same tone been his habit. The models of his thought, all but impeccable accuracy, careful research, and well-chosen objects, as the writings of Francis Baily.

BALA LIMESTONE, one of the most interesting of the carbonaceous deposits which have been examined by Professor Sedgwick in the midst of the older sandstone rocks of North Wales. There are two bands of this rock, exhibited on the west of the Berwyn mountains and on the east of Bala Lake. Two miles north-east of Bala, the limestone, and the schistose rock, are so nearly alike that they may be well said to have the same appearance: they are both of the same age, and must have been formed at the same time, in the midst of the same sea. They are both of the thickness of six miles. The upper of these two bands is the best known, as being the most accessible. It is quarried for lime, and is in many places still covered by a ロウ下部に石炭層の発見がある。これらの層は、灣と湖の東で、再び湾の東で見られ、これらは同じ時代に形成され、同様の海の中で形成されたと考えられる。それらの厚さには、6マイルの違いがある。上の二層は最もよく知られ、石灰の採取場所であり、一部はまだ被覆されている。上部の石灰岩帯は、湾の西や湖の東で見られる。二マイル北東のBalaでは、石灰岩とその隣接する石灰岩の層は、同じように見え、これらが同じ時代に形成され、同様の海の中で形成されたと考えられる。それらの厚さには、6マイルの違いがある。上の二層は最もよく知られ、石灰の採取場所であり、一部はまだ被覆されている。
Rigaud. It forms the frontispiece to the 'Recueil d'Estampes après les plus célèbres Tableaux de la Galerie de Dresden.' It was done in 1755, but the subject is a modern one. A number of characters were painted on canvas, he retained some of the impressions, and even damaged the plate before he sent it to the king, at whose expense it was engraved. His right of election to be a member of the French Academy of Painting, of which he was Aigré, equivalent to our Royal Academy, was forfeited in consequence, and he retired to Avignon, where he died in 1704.

(Heineken, Dictionnaire des Artistes, &c.; Wattelet et Levesque, Dictionnaire des Arts, &c.; Huber, Manuel des Artistes d'Académie.

BALLEN, HENDRICK VAN, a distinguished Flemish historical painter, and the first master of Vandyck and Snider. He was born at Antwerp in 1590. He went early to Rome to study his profession, having acquired the rudiments from Anan van Oort.

He was an excellent colourist, a good draughtsman, and painted with great facility. Of his works, which are numerous, one of the best is St. John in the Wilderness, an altarpiece in one of the chapels of the Cathedral of Antwerp; the background is by Velwert Breugel, who painted the landscape backgrounds of many of Van Balen's pictures. He died in 1632, and was buried in the church of St. Jacques at Antwerp. Vandyck painted his portrait; and it has been engraved by Van Helmont. The painter Jan Van Balen was the son of Hendrik. (Van Mander, Luver de Skilderen; Descamps, La Vie des Peintres Flamands, &c.; Heineken, Dictionnaire des Artistes, &c.)

BALISTA, ANTONIO, a distinguished painter of Verona, where he was born in 1666. He was brought up as a merchant, but before his 21st year he was studying as a painter under Bellucci at Venice. He afterwards studied under Maratta at Rome, and he eventually painted much more in the style of the Roman than of the Venetian. He however combined the chief beauties of Venetian colour with the characteristic correctness and solidity of design of the Roman school.

He is one of the most able painters of his time, and instructed at Venice a numerous school, in which were educated several very distinguished painters, as Giambattista Mariotti, Giuseppe Nogari, and Pietro Longhi. Lanzi mentions particularly, by Valesio, a Nativity, and a Deposition from the Cross, at Venice; a Santa Chiara at Padua; and a San Vincenzo, at the Dominicans, in Verona. He died in 1734, according to Guarienti, but in 1740, according to Zanetti and Oretti. Heineken mentions many prints after the works of this artist, which is equal in merit with those of himself. (Zanetti, Della Pittura Veronese; Lanti, Storia Pittorica, &c.; Heineken, Dictionnaire des Artistes, &c.)

BALISTICOCHUS. A fossil plant in the laminated lithographic limestone of Pappenheim, is named Balistochus, from the Greek 'balistos,' to throw.

BANA'NA. [Musa, P. C.]

BANDANAS, or BANDANNAS, a term originally applied to a peculiar kind of silk handkerchief made by the Hindoos, is the name now commonly given to silk and cotton handkerchiefs manufactured in this country, and decorated with patterns of similar character, though by a very different process. The distinguishing peculiarity of a handana handkerchief is that it has a uniformly dyed ground, usually of bright red or blue, ornamented with circular, lozenge-shaped, or other simple figures, either perfectly white, or in some cases of a yellow colour. These spots are said to be produced, in real Indian bandanas, by tying up the parts intended to be different colours, and then媒染ing the handkerchief to the action of the dye, and thus protecting them from it. Such as this process appears, British manufacturers were, owing to the difficulty of imparting a sufficiently durable ground-colour by the ordinary process of calico-printing in India, unable to imitate it. The following process, until a plan was contrived for dyeing the whole surface, and afterwards discharging the colour from the spots forming the pattern by the agency of chlorine; a plan which, according to the account in the 'Dyle' referred to below, was invented by M. Koechlin, of Mülheim, in 1802, has been carried into effect on a large scale at the Barrowfield Dye-works near Glasgow, by Messrs. Monteith and Co., with a degree of perfection far exceeding the original oriental bandana.

The object of this notice being simply to describe the peculiar method of discharging the colour from the spots, it

is unnecessary to detail the processes by which a uniform colour is imparted to the whole surface of the cloth, on both sides. A number of the half-workings, when they are taken to an apartment containing a range of powerful hydrochloric acid and discharging-presses, each of which has a roller at the back, to receive the cloth to be operated upon, and another in front, to receive it after the pattern has been discharged; the intermediate roller being raised to a height of two feet above the press, which is about a yard square, or equal in size to a single handkerchief. This bed-plate is formed of lead, perfectly smooth and even, and is perforated with holes corresponding with the white spots of the desired pattern; and a similar perforated bed of zinc or copper is fixed at a short distance above it. Fourteen pieces of dyed cloth being laid carefully upon one another, are rolled together upon the back roller of the press, and acted upon simultaneously; and, when discharging and washing are completed, the cloth is worked through the press, the cloth being sometimes facilitated by a powerful current of air. The extreme tightness with which the dyed cloth is compressed prevents the action of the bleaching-liquid from extending beyond the perforations; and as mechanical contrivances have been applied to the discharge of the perforations in the two leaden plates, the pattern produced by them is very accurately transferred to the cloth. After allowing a few minutes for the action of the bleaching-liquid, it is drawn off, the pressure is removed, and the portion of both which has been operated upon is placed on the front roller, a second portion being, by this operation, drawn forward upon the bed-plate, for a repetition of the process. By means which will be readily understood by those conversant with dyeing, the portions of the cloth, each with a perforation of fifteen into action, so that one discharger, with his assistants, can keep the whole in constant operation. The whole routine of operations occupies about ten minutes, so that the sixteen presses (each producing fourteen handkerchiefs at each operation) will discharge 2,564 handkerchiefs at each hour. After working, the whole being completed within the short space of time mentioned above, and, by the aid of powerful and ingenious machinery, requiring only the labour of four men to effect the various necessary changes and adjustments. A much fuller account of this process, with the details of the discharging press, is given in Dr. Urns Dictionnaire des Arts, art. 'Bandanna,' and a minute though popular description of the whole manufacture in Dods's Textile Manufactures of Great Britain, pp. 78-93, and the Penny Magazine, vol. xxii. pp. 591-593.

BANDON, River. [Cork, P. C.]

BANDON, or BANDON-BRIDGE, an Irish corporate, market, and post town, partly in the parish of Kilbrogan in the barony of Killmealy; and chiefly in the barony of Kilmore and East Carberry (East Division); all in the county of Cork: 20 miles south-west of Cork, and 146 south-west of Dublin. The town is situated on the main road of the 15,638 statute acres, with a population in 1841 of 14,702.

The town was founded by the English settlers on the forfeited estates of the Earl of Desmond, in the reign of Elizabeth, and takes its name from a bridge over the river Bandon, which flows through the parish of Kilbrogan into the still-name, the county of James I. or Charles I., a colony of Protestants from Bristol; and as the town was walled, it became, in the great civil war of 1641, the chief place of refuge for the Protestants of the neighbourhood, and several conflicts took place between the townsman and rebels and the revolted
Irish. On Cromwell’s approach, the inhabitants declared for the Parliament. In 1688 they expelled the garrison placed here by James II., but were obliged soon after to submit to a detachment of his army. At this time the walls were razed, and have never been rebuilt.

The area is more comprehended in the boundaries of the parliamentary borough, as determined by the Irish Boundary Act (2 & 3 Will. IV. c. 89), and consists of several streets on both sides the river Bandon, which has a course nearly due east, and over which there is a bridge. The streets are indifferently paved, and on every side the area of the parliamentary borough is 447 statute acres; it contained, in 1841, 1256 houses, namely, 1180 inhabited, 74 uninhabited, and 2 building; with a population of 1760 families, or 7791 persons; of which 730 were stated in 1807 families, or 9917 persons; the number of houses was 1650, namely, 1456 inhabited, 137 uninhabited, and 7 building.

As the present parliamentary limits embrace a larger portion of the town than those of 1831, the number both of houses and inhabitants must have materially decreased in the ten years 1831-41. Of the inhabited houses in 1841, 168 were of superior character; 665 smaller, of from five to nine rooms, but substantial; 274 were mud cottages of more than one story; and 373 were rooms of one story only. Of the houses of Ballymodan and Killaroben are both in the town; the latter on the north, the former on the south side of the river. There are a spacious Roman Catholic chapel, and a nunnery of the Order of the Presentation, with a conventual church; a Presbyterian meeting-house; a Freshfield Meeting-house, in connexion with the synod of Munster, and places of worship for the Primitive and Wesleyan Methodists.

Bandon was incorporated by charter of 11 James I. (a.d. 1614). The corporation, before its abolition by the Irish Municipal Reform Act (3 & 4 Vict. c. 108), consisted of a provost, 12 burgesses, and an unlimited number of freemen. The borough returned two members to the Irish Parliament; but by the Municipal Reform Act the right of election was limited to the mayor and burgesses. The boundary of the borough was enlarged by the Irish Boundary Act. The constituency in 1855-6 was 367; in 1840 it was 460, showing an increase in the interval of the only 33 persons.

The living of Ballymodan is a vicarage, of the yearly value of 414l. gross, or 367l. clear; that of Killaroben is a rectory and vicarage, of the yearly value of 719l. gross, or 650l. clear; both are in the diocese of Cork. There were in the two parishes, in 1854, 17 day-schools with 1555 children on the books, namely, 564 boys and 791 girls. Of these schools one was a classical school founded by the Earl of Burlington, and partly supported by a grant from the Duke of Devonshire; and in the other three, of very small number, not supported by endowment or subscription. One, of 350 to 400 girls, was taught by the nuns of the order of the Presentation. Three schools, for boys, girls, and infants respectively, were taught by the Duke of Devonshire, and supported by the Duke of Devonshire and schools for boys, girls, and infants were supported by the Wesleyans. Beside the day-schools there were, in two parishes, three Sunday-schools with 667 children.

Bankruptcy. Within the last twenty years (since 1836) there have been three important acts passed relating to the law and administration of bankruptcy—first the general Bankruptcy Act (5 & 6 Will. IV. c. 16), which consolidated, and simplified the law; secondly, the act 1 & 2 Will. VI. c. 56, which constituted the Court of Review and a local Court of Bankruptcy for London; and thirdly, the act 5 & 6 Vict. c. 123, which made some alterations in the law and also established county courts of bankruptcy. The last act has been passed since the article BANKRUPTCY, P.C., was written, and came into operation on the 11th of November, 1842.

By 5 & 6 Wm. IV. c. 29, the judges of the Court of Review were reduced from four to three; and by 5 & 6 Vict. c. 123, the court is formed of one judge (§ 64). One of the new vice-chancellors is now chief judge of the Court of Bankruptcy.

Before the passing of 5 & 6 Vict. c. 123, the mode of working bankruptcies in the country was as follows:—One hundred and forty separate lists of commissioners (each list containing the names of two barristers and three attorneys) were appointed by the Lord Chancellor, on the nomination of the judges, to act in one hundred and thirty-two different cities and towns throughout England and Wales (exclusive of London); and flats in bankruptcy were directed to the commission of the judges of the Court of Bankruptcy for that district.

Under 5 & 6 Vict. c. 122, the Privy Council is empowered to select towns for the establishment of district courts of bankruptcy, and to fix or alter the extent of their jurisdiction. The act limits the number of commissioners of district courts to twelve, who must be serjeants, or barristers of seven years' standing, and each of them is competent to exercise the jurisdiction of the court. Their salary is 2000l. a year. The number of commissioners appointed for each court is fixed by the Court of Bankruptcy, and is limited to one (with a sub-deputy), with two registrars, and from two to four official assignees. The district courts are auxiliary to each other for proof of debts and examination of witnesses. Fees are accommodated for to the chief registrar of the Court of Bankruptcy in London.

The district courts of bankruptcy already established are at Birmingham, Bristol, Exeter, Leeds, Liverpool, Manchester, and Newcastle. The district assigned to each court varies from the smallest to the largest county borough. The Court of Bankruptcy has an extensive local jurisdiction, and includes a city of so much importance and so far distant as Norwich. The affairs of a bankrupt who has carried on business in the southern part of the county of Nottingham are administered at the bankruptcy tribunal at Birmingham; but if the trader has resided in the northern part of the county, the flat is worked at the Leeds court. It is alleged that the present mode of administration occasioned loss of time and great expense to the estate, and the distance of the district courts, and some other objections are made, which may be removed without much difficulty. Thus the practice of the Leeds court might be made general. The Leeds commissioners, 'with a view to avoid the heavy charges of the petitioning creditor, solicitor, and others travelling a distance of from forty to seventy miles, and for their loss of time, have determined to receive the proofs of the petitioning creditor's debt, &c. upon deposittes made out of court, and have called upon the other commissioners to follow the example.' Before the district courts are established, a registrar of bankrupts, and has directed the messengers, instead of themselves travelling to secure the effects of the bankrupts, to employ deputies in the nearest towns. If the district courts are proved to be a better tribunal in bankruptcy than the old law, it is proposed to reorganize the commission of bankruptcies so as to divide the country into smaller jurisdictions. A court at Sheffield, for example, would be a great advantage to that town, and would bring Nottingham one-half nearer to a court than it is at present; and although the present number of seven or even a dozen courts might not be locally so convenient as the former large number of one hundred and thirty jurisdictions, it must be recollected that railways have diminished three- or more the distance in flats of bankruptcy in every place, and in some places the number of miles has become equal only to sixteen. Sufficient experience has scarcely yet been obtained of the advantages or disadvantages of the plan of district courts. The only official return which has been made is of the number of petitions received when the new courts had been only established about a year. It purports to show the amount of solicitors' and messengers' bills, up to the choice of assignees, in the first twenty flats removed into the district courts, and of the first twenty registers in each court.

This return, an abstract of which is subjoined, is not so complete as could be wished:

In the return from the other three courts the solicitors' and in one or two instances the messengers' costs are stated:
The Bankruptcy Act, c. 122, &c., 1843, has added to the list of persons who may be declared bankrupts, such as -Liverty-stable-keepers, coach-proprietors, carriers, shipowners, auctioneers, apothecaries, market-gardeners, cow-keepers, brick-makers, slum-owners, lime-burners, and william-pit-manufacturers. 

The Bankruptcy Act of 16 Geo. IV., c. 16, [Bankrupt, P. C., p. 991] must be satisfied with the relief that they can obtain as insolvent debtors. By 7 & 8 Vict. c. 70, a person not being a trader within the meaning of the Bankruptcy Acts may present a petition to the Court of Bankruptcy, and on compliance with the terms of the act may effect a composition of his debts and debts protection from arrest; and by 7 & 8 Vict. c. 96, a trader who owes less than 300l. may obtain a similar advantage. By the same act, the court may order the executor, administrator, or assignee of the bankrupt to be examined as to the assets of the bankrupt, and the number of creditors who have proved debts above 20s., or after six calendar months from the last examination of the bankrupt, either by three-fifths in number and value of such creditors, or by nine-tenths in number of such creditors. But the recent statute of 5 & 6 Vict. c. 126, dispenses with the previous signatures of the creditors, and the court, which is authorized to exclude any person as a bankrupt, may order any person to be a discharge from the court, but the judge will judge for itself of the validity of such objections as are made, and either find the bankrupt entitled thereto and allow the same, or refuse or suspend it, or its terms. Such a certificate must be afterwards confirmed by the Court of Review, against which confirmation any of the creditors may be heard before the court. Gambling or misconduct on the part of the insolvent or concealment of property, fraudulent entries in his books, being privy to the proof of false debts, &c., disentitle a bankrupt to his certificate under the act 5 & 6 Vict. c. 122, much in the same way that it did under previous acts.

The salaries of the judge, commissioners, and other officers of the Court of Bankruptcy, amounted, in the year ending 1st of January, 1844, to 45,832l.; and 12,396l. were paid to the same officers in the year 1843. The court is empowered to order retiring annuities of 1500l. a-year to the judge, and of 1200l. to the commissioners; and also retiring annuities of different amounts to the accountant in bankruptcy, registrar, &c. The sums paid out of the fund entitled the 'secretary of bankrupts' account.'

The number of bankruptcies gazetted in England and Wales in 1842 was 1273, in 1843, and 1064 in 1844. About one-half of this number occurred in the metropolis and in Lancashire and the West Riding of Yorkshire.

The main features of distinction from the immediately previous act (54 Geo. III. c. 137) are these:—It enlarges the class of persons who may be subjected to the process; instead of being a process of which every step must be taken in the supreme court, the Bankruptcy Law Court is vested with original jurisdiction in bankruptcy, and the taking the process out of court require the sanction of the supreme judiciary. Sequestration reduces the interest of
which will qualify a creditor to sue for the application of the act and abbreviates the proceedings.

The claim of persons coming within the 2 & 3 Vict. c. 41, are enumerated as any debtor who is or has been a merchant, trader, manufacturer, banker, broker, warehouseman, warfinger, underwriter, artificer, workman, packer, builder, carpenter, wharf, inn-keeper, hotel-keeper, stable-keeper, coach-contractor, cattle-dealer, grain-dealer, coal-dealer, fish-dealer, lime-burner, printer, dyer, bleacher, fuller, calenderer, and generally any debtor who seeks or has sought his living or a maintaining himself, or any partner with another, or as agent or factor for others, by using the trade of merchandise, by way of hargains, exchange, barter, commission, or consignment, or by buying and selling, or by having and letting for hire, or by the ownership or control of any part of the business indicated above, (§ 5) unless the debtor consent to the sequestration, he must have been bankrupt, or must have been sixty days in sanctuary within the space of a year, and must have transacted business in Scotland, and must within the preceding year have resided or had a dwelling-house in Scotland. The estates of a deceased debtor may under certain restrictions be sequestrated though he was not bankrupt, and did not come within the above classification. The debt of the petitioning creditor must be 50l.; if two partners, 100l.; if three partners, 150l.; if four partners, 200l.

The Irish law of bankruptcy has been gradually assimilated to the English law by several recent acts (6 & 7 Will. IV. c. 14; amended by 1 Vict. c. 48, and 2 & 3 Vict. c. 86). There is no separate court of bankruptcy; but there are two commissioners who are empowered to act by a commission under the Great Seal. There are no official assignees with gold bullion, but under the 3 & 4 Vict. c. 84, an English Act, one-half of the amount of the notes of any private bank, limited to 2,500l. in debt, may be delivered to a commissioner of bankrupts.

In 1841 an act was passed by Congress to establish a uniform system of bankruptcy throughout the United States of North America. The act came into operation in 1842.

In June, 1853, the French law of 1850 on bankruptcy and insolvency was adopted, and an entirely new law was promulgated, which now forms Book III. of the Code de Commerce (Des Faillites et Banqueroutes).

BANKS. The object of this notice is to show the regulation and discipline which banking institutions in this country are now placed.

Bank of England.—The act 7 & 8 Vict. c. 32, passed 18th July, 1844, provides for the complete separation of the ordinary banking business by the establishment of a distinct department of the bank, called the 'Issue Department,' the sole business of which consists in the issuing of notes under regulations contained in the act. The directors were required, on the 31st of August, 1844, to place the credit of the Issue Department, consisting of 14,000,000l., in the form of the debt owing by the public to the bank, and 2,984,900l. of Exchequer Bills and other government securities; and also so much of the bullion and coin as is not required in the banking department. The amount of securities thus placed exceeds, however, the amount of the Issue Department, with one exception. The bullion consists of gold and silver bullion (the silver not exceeding one-fourth of the gold), constitute the basis for regulating the issue of notes. For example, in the week when this plan came into operation, the amount of notes in circulation were 28,251,025l., and the amount of securities and coin and bullion which the bank held was the same, consisting of the debt due to the bank by the government, 11,015,100l.; other securities 2,984,900l., making 14,000,000l.; gold coin and bullion 12,657,208l., and silver 5,999,500l. — the total amount of the securities may be diminished, but cannot be increased beyond the sum of 14,000,000l., except in a specified case, which will be presently noticed. The expansion or contraction of the note circulation depends therefore upon fluctuations in the stock of coin and bullion. Persons may demand notes of the Issue Department in exchange for gold bullion at the rate of 34. 17s. 6d. an ounce, but the cost of melting and assaying is at their expense. As bullion continues to be coined, a new set of notes is issued, and as bullion is withdrawn, the amount of notes is diminished. The amount of bullion will cause a contraction in the issue of notes. Thus the principle of convertibility is effectually applied to the circulation of the bank by rendering its issues dependent on the supply of the precious metals. The Issuing Department is not to be considered as having a monopoly of the right of coinage. The issue of notes is increased except in exchange for gold, without the express consent of three members of the ministry (the First Lord of the Treasury, the Chancellor of the Exchequer, and the Master of the Mint;), and the profits on the circulation of the bank beyond the sum of 14,000,000l. is issued on its own securities, are to be enjoyed by the public. The securities may also be increased beyond the sum of 14,000,000l. when any bank ceases to issue notes, and the Bank of England may then be authorised by Act of Parliament to assume the liabilities of the discontinuous bank, up to the sum of two-thirds of the sum to which the bank which ceases to issue was limited. On the 4th of January, 1845, nine country banks had ceased to avail themselves of the privilege of issue. Their aggregate circulation was 190,493l., a return, of which a copy in public in course of the next session, is required to be made weekly by the Bank to the Commissioners of Stamps for publication in the London Gazette.

By the act of 1844 a further claim has been made upon the bank by the public. The provisions of the 3 & 4 Vict. Wm. IV. c. 98) provided for the reduction of 190,000l. as the cost of managing the unfunded debt, but by the last act the sum of 180,000l. is in future to be deducted. The privileges of the bank may be abrogated or modified on giving twelve months' notice, after the 1st of August, 1855.

Private Banks.—Besides the enactments which relate to the Bank of England, the 7 & 8 Vict. c. 98, contains very important provisions for regulating other banks and their issues. No new bank of issue can henceforth be established in England, or in any part of the United Kingdom, if the said bank have issued notes who were issuers on the 6th of May, 1844; and should cease to issue, they cannot resume this branch of banking business. The privilege of issuing notes also if a bank which was issuing notes on the 5th of May, 1844; be in the hands of their present partners, will be debarred to be in the firm in above six. The issues of each bank are limited to its average circulation for twelve weeks preceding April 27, 1844; and after the 10th of October following, the amount of issues on an average of four weeks was not to exceed the average monthly balance of the bank's issues. All banks of issue are required to make a return to the Commissioners of Stamps for publication in the London Gazette, of the amount of their notes in circulation on every day during the week, and of the average of the week. A like average for every period of four weeks is returned monthly; and the average monthly balance of all the weeks, during which private from joint-stock banks, are also published in the London Gazette. The penalty for making a false return of issues is 100l.; and, with the consent of the 'Treasury, the Commissioners of Stamps may inspect bankers' books, under a penalty for refusal of 100l. By 3 & 4 Vict. c. 84, the return of circulation were only required quarterly; by 4 & 5 Vict. c. 50, monthly; and by 7 & 8 Vict. c. 98, they are to be made weekly; and an annual return is to be published of the weekly returns of each bank for the 11th April, for the year.

Joint-Stock Banks.—All banks which have more than six partners are termed joint-stock banks, and their establishment was first permitted by 7 Geo. IV. c. 46, passed in 1826; but they were not allowed to issue notes in London or within thirty miles of the metropolis, or on foreign exchange, or to make bills for any less period than six months. Beyond these limits joint-stock banks might issue their own notes, and in all essential points they were on the same footing as private banks. Joint-stock banks increased so rapidly, that in January, 1839, there were established in England and Wales 108 banks, with 648 branches, and 32,142 partners, and a large number of private banks were thrown open to a joint-stock proprietary. Through the fault of the legislature not providing for the regulation of joint-stock banks, a very high proportion of these banks were conducted with a reckless disregard to sound principles of banking, which not only involved the shareholders in ruin, but were injurious to the general interests of the country. In 1838 a select committee of the House of Commons reported on the defects of joint-stock banks. The law did not require a revision of the deed of settlement by any competent authority, and was not sufficiently stringent to secure the registration at the stamp-office of such deeds of settlement. The amount of the capital raised by joint-stock banks, or the amount of the townships, were responsible to the public. The amount of nominal capital varied in different banks from 100,000l. to 5,000,000l., and in one case an unlimited power was reserved of issuing shares to any extent, while at the same time any dividend was to be paid with the capital. Shares were frequently sold at a discount of 95 to 100l., and in some cases the amount of shares was subscribed for all. No rule was enforced with respect to the nominal amount of shares, which varied from 5s. to 1000l., nor with respect to the amount of paid-up capital.

England and Ireland. Persons whose names are in the memorial last delivered, are themselves or their representatives liable to legal proceedings, as existing shareholders. When joint-stock banks were first established, each shareholder was answerable to the whole extent of the property. By 1 Vict. c. 73, they were rendered liable only to the extent of their shares, but the liability did not extend to the shareholders as a body. By 7 & 8 Vict. c. 113, the liability of any shareholder extends equally to the whole body of shareholders as a company; but if execution upon any judgment against the company shall be ineffectual to obtain satisfaction, then any shareholder may be proceeded against. The acts of an individual partner were formerly binding on all the other shareholders, but it is only the acts of an individual director or other officer properly appointed which are now binding on the co-partnership.

The charter of the Bank of Ireland, which would have expired on the 1st of Jan., 1838, was renewed, but it may be withdrawn on twelve months’ notice after 1st August, 1845. The monopoly is far stricter than that of the Bank of England. No joint-stock bank can issue notes, or draw or accept bills, within sixty-three statute miles of Dublin, and beyond these limits they can neither draw nor accept bills for a less sum than 50L, nor for any sum upon demand. The district within 63 miles of Dublin contains a population of 1,500,000, and the Bank of Ireland has here only established six branches, while in the various towns of Ireland beyond the 63 miles limit there are above one hundred branches of joint-stock banks. The Bank of Ireland has altogether twenty-four branches.

In Scotland there are no joint-stock banks, but banking is enjoyed by any particular establishment, but both in Scotland and Ireland the currency of bank-notes under 5l. is allowed by law, and it is interference with this peculiarity of their banking systems that is most feared, especially in Scotland.

**Statistics of Banks and Banking**

1. The Bank of England made quarterly returns of its circulation, deposits, securities, and stock of bullion, to the end of 1842; after which these returns were made monthly, until August, 1844, when a return in the form given below began to be made weekly.

An account, pursuant to the Act 7th & 8th Vict., cap. 92, for the week ending on Saturday the 25th day of Jan., 1845:

**BAN**

| £30,325,729 |

The number of joint-stock banks in the United Kingdom on the 1st of January, 1844, was as follows: in England and Wales 114; Scotland 21; Ireland 13; besides 10 joint-stock colonial banks in London. Many of these banks are in a highly prosperous condition, and some have been well conducted from their first establishment. The London joint-stock banks are excluded by the private bankers from the clearing-house. Banks in Ireland and Scotland.—No alteration has taken place in the constitution of the banking institutions of Scotland since the act Banking, P. C., was written. In the speech of the Bank in the third session of 1845, Her Majesty adverted to the state of the law as it stands to the privileges of the Bank of Ireland, and to other banking establishments in that country and in Scotland, as likely to engage the attention of Parliament.

The act relating to joint-stock banks contains some other provisions which are deserving of notice as improvements. Every year, between the 20th of February and 20th of March, a return is required from the ministers of Stamps, setting forth, amongst other particulars, the name, style, and firm of the banking company, the names and places of abode of the several members thereof, and of the directors, treasurers, &c.; but not twenty years of such annual value as shall be expressed in each letters patent.

The balance of assets over liabilities, being 3,209,696£, is stated in the above account under the head `Rest'.

The stock of bullion held by the Bank of England (both gold and silver coin being included in the term bullion) indicates various circumstances connected with the state of trade and with the general condition of the country; and the following table, which shows the stock of bullion in February and August in each year since 1829, is therefore given:

<table>

Sometimes the stock of bullion properly so called exceeds the amount of coin, and sometimes the proportion is the reverse. In the four weeks ending Dec. 14, 1841, the amount of gold coin was 4,270,000£; and of gold bullion 995,000£. In the four weeks ending Sept. 17, 1842, the amount of gold coin was 2,750,000£; and the stock of gold bullion, which had been gradually increasing since December, 1842, was 7,106,000£. In January, 1844, the proportion of each was nearly equal. On the 4th of November, 1843, the bullion held by the Bank amounted to 12,036,000£, and consisted of gold bullion 6,999,000£; gold coin 4,244,000£; silver bullion 1,737,000£; silver coin 63,000£.

2. The average circulation of 208 private banks and 72 joint-stock banks in England and Wales, for the twelve weeks ending April 27, 1844, was:—

| Private Banks | 5,153,407 |
| Joint-Stock Banks | 3,475,446 |

This return was obtained, as already mentioned, with a view of fixing limits to the issues of notes. They cannot be increased beyond the amount certified in April, 1844. This total aggregate circulation of 8,648,853£ was divided amongst 280 banks in the following proportions:—

The aggregate circulation of private and joint-stock banks, in England and Wales, for the weeks ending Jan. 4, 1846, was:—

Barbara, a genus of plants belonging to the natural order Crucifereae. It has a terebinthine odor, the valves convex, and a prominent longitudinal nerve; the stigma capitate, the seeds in a single row. Barbarae belongs to the first sub-order of Crucifereae, Silicaceae, which possess a linear or linear-lanceolate pod opening by two valves. The species of Barbarae are perennial herbs, &c. Stereocarpus and erect stems. The
flowers are yellow, arranged in racemes; the pedicels without bracts.

*B. vulgaris*, common Yellow Rocket, common Winter Cress, Herb St. Barbara, has the lower leaves lyrate, upper pair of lobes as broad as the larger roundish subterminal lobe, the uppermost leaf undivided, toothed; young pods obliquely erect; seeds scarcely larger than broad. It is a native, in damp moist places, of Great Britain and throughout Europe; also cultivated in gardens for the fresh taste, and is sometimes cultivated as a spring salad. In Sweden the leaves are boiled and eaten. It is often cultivated in gardens, especially a double variety, which forms a handsome border-plant.

As in *B. vulgaris*, the Winter Cress, has the lower leaves lyrate, upper pair of lobes as broad as the roundish subterminal lobe, uppermost leaf pinnatifid, with linear oblong entire lobes. This plant is a native of France and Great Britain; it is found nowhere else in America. *B. sylvestris*; in French, *Creason d'Amérique*. It is also known in England as American Cress, Black American Cress, French Cress, and Belle-Isle Cress. It is used as a salad, and is more bitter than the common water-cress. It can be raised for eating all the year round. In cultivating it, should be grown from seeds, a quarter of an ounce of which will serve for sowing ten feet of drill. For winter and spring use they should be sown in the last fortnight of August or beginning of September, on a warm sheltered border. For summer use they may be sown from March to August, in a sunny or a shaded situation being chosen according to the season. They require water occasionally in dry and hot weather. In winter the plants should be sheltered, either by covering them with a layer of bracken, reeds, or straw. After the leaves are cut the stem should be allowed to remain for another gathering. The finest plants may be allowed to run to seed.

*B. arcuata* and *B. stricta* are two species described by Barclay, and lately introduced to the British Flora. A few others are found in the northern parts of Europe and America. With the exception of the double yellow rocket, none of the species are worth cultivating as ornamental. This plant may be propagated by cuttings, suckers, or dividing the plants at the root.

**BARCKHAUSIA**, the name of a genus of plants belonging to the natural order Compositae, the tribe Cichoroaceae, and the subtribe Lactuceae. It has many-flowered heads, a double involucre, the inner of one row, the outer of short fail scales; the fruits 4-angled, all (or the inner ones only) gradually contracted into a long beak. This genus has several European species, two of which only are natives of Great Britain. The flowers are yellow or pale purple. Some of the species are cultivated in gardens, where they form a pretty and easily cultivable border-plant. The British species are—

*B. tenuzascifolia*, with rough runcinate-pinnatifid leaves, erect heads, yellow flowers, and slender, hairy, tomentose, its outer scales ovate-lanceolate with a membraunig margin, herbaceous bracts, the fruits all equally beaked. *B. fistulosa*, with hairy runcinate-pinnatifid leaves, nodding unopened heads, hairy and downy involucre as long as the pappus, its outer scales lanceolate, acute, downy; the marginal fruits slightly beaked, shorter than the involucre, central ones with long beaks equaling it. The first species has a stem one or two feet high, yellow flowers, purplish beneath, and is found in uncommon places. The second is 3-4 feet high, its leaves 8-16 inches in height, with yellow flowers. It grows in chalky places in England, but is a rare plant.

*B. setosa*, a German species, has been lately found in several districts in Great Britain, but it appears most probably that this species has been introduced by means of ornamental and other seeds used for agricultural purposes.

**BARCLAY, Jane**, a Scottish lady, father of the author of *Argenvis,* was born in Aberdeenshire, in 1646. In early life he attached himself to the court of Mary Queen of Scots, but the misfortunes of that princess closing the path to preferment, he resolved to seek his fortune in the New World. In November of the period, he studied civil law under Cujas at Bourges. In 1718 he became professor of law in the then newly erected University of Pont à Mousson, of which his uncle Edmund Hay was the first rector. In 1706 he published a work in favour of despotic principles; *De Regno et Regali Potestate, adversus Buchananum, Brutum, Bou-
Rome; where Bayle says he enjoyed the patronage of Paul V. He there in 1617 published "Pararamis ad Scortas," a book more likely to be acceptable to the Holy See than his other works. In 1631 he published the "Lettres," by which his name has been best known, 'Argenis': this is a romance full of incident and description. The style has received the commendations of the greatest scholars, and Grotius, whose life of him runs to 50 folio pages, is of the opinion that by which his name has been best known, 'Argenis': this is a romance full of incident and description. The style has received the commendations of the greatest scholars, and Grotius, whose life of him runs to 50 folio pages, is of the opinion that

BARCLAY, JOHN, a Presbyterian clergyman, and founder of the small sect called Barers, whose peculiar standard of faith is contained in the 11th verse of the 17th chapter of the Acts of the Apostles, where it is said of the Jews of Berea: "They received the word with all readiness of mind, and searched the Scriptures daily, whether those things were so." He was born at Newtush in Forth, in 1734, and studied at the University of St. Andrews, where he took the degree of A.M. While attending the course of divinity at that university, he became conspicuous as a supporter of Archbishop Campbell, a promulgator of doctrines which his ecclesiastical charge with the Scotch Presbyterian Church. In 1759 he was licensed as a probationer by the Presbytery of Auchterarder, so renowned in the late discussions in the Church of Scotland. He was for some time assistant to Mr. Johnson, minister of the parish of Errol in Perthshire; but after some acrimonious discussion, arising apparently from Barclay's inculcating his own peculiar views from the pulpit, that connection was broken. In 1763 he became assistant of the Church in Ayr-shire. Here he became the great popular preacher and religious leader of the district, and attracted crowds of auditors from the neighbouring parishes. He appears to have carried to exceed the prevalent characteristic of the Evangelical Presbyterians in that part of the kingdom, and these are the sects which make the nearest approach to them. In 1766 he published a paraprase of the Book of Psalms, with a Dissertation on the best means of interpreting that portion of Scripture. Some of its doctrines and sentiments were so far taken up with the zeal of his presbytery, and proceedings were commenced against him, which however seem to have gone no farther than a reprimand. The spirit of theological disputation being raised, he published pamphlets from time to time calculated to throw contempt on the death of the clergyman to whom he was assistant, in 1772, the presbytery not only defeated his attempt to be appointed successor, but refused him the necessary testimonials for acceptance elsewhere, and expatriation to Scotland, and became the leader of a sect of which a few congregations still exist. He preached for some time in Edinburgh, and subsequently in London and Bristol. In London he kept open a debating society, where he supported his doctrines against all impugners. He died on the 29th of July, 1798. He published several works in which he expounded his own peculiar doctrines; above all, the "Preacher's Study," of which the first edition, in 1762, has been reprinted. Like most sect-founders, he was a man of ardent and restless temper and daring powers. A memoir of him was supplied to Chambers's 'Biographical Dictionary of Eminent Scotsmen.'

BARON, ERASMUS, the younger, as Batavia's greatest historian. His name remains conspicuous in the annals of Dutch literature, and the "Dichter van de Zee," he is called in the country of his nativity, which was situated favourite seat of his contemplations. As Batavia's great he eny 8
researches and compilations which were the business of his laborious life. Thetford was the scene for nearly twenty-five years: and the mysterious castles O. T. N., with which it was one of his winter descents, his name in the index, was merely intended to indicate the town and county of his residence. The last few years of his life were marked by painful reverses of fortune. They were spent chiefly in London, where he died, after a short illness, on the 23rd of March, 1778.

Mr. Barker's writings in classical philology and criticism were numerous. He was a constant and leading contributor to Mr. Valpy's Classical Journal, almost from its commencement; and his name is also to be found in connection with his to other periodical publications. He edited, with English notes, for the use of schools, portions of several of the classics, both Greek and Latin; among which were works of Æsop, Caesar, Tacitus, and Cicero, of Xenophon and Demosthenes. But his labours were not confined to the classics; for with foreign scholars engaged him also in the superintendence of several works of other men: the chief among which were, the English impression of Anthon's edition of Leman's Classical Dictionary, and of Noah Webster's English Dictionary.

But Mr. Barker's name has been known most widely, both for praise and censure, through his contributions to Greek lexicography. The latest work of this kind in which he engaged was the Greek and English Lexicon published in 1831, in which he was the coadulator of Professor Dunbar of Edinburgh. But an undertaking at once more laborious and more unlooked for was Mr. Valpy's spirited reprint of Henry Stutfville's 'Angel flying away after death', in 10 vols. fol. Although the editorship of this work was described as vested in more than one person, and still the names of the editors were never unequivocally announced, yet it was understood universally that the severe duties involved in the editorship were really performed by Mr. Barker almost without any assistance. The Index cost him three years' labour. In 1819, after the publication of a few parts, the work was most severely criticised in the forty-fourth number of the Edinburgh Review. Mr. Barker: no doubt, took it as a reflection on his character. But his mind had inherent defects which no schooling could have quite eradicated. It was eminently deficient both in comprehensiveness of thought and in logical closeness of argumentation; and his taste was as defective as his judgment. His merit consisted, as Dr. Coleridge observed, not of the philologist, or even the critic. But he earned faithfully, and deserves to obtain without reserve, such praise as may be challenged by unwaried and disinterested labour. No man worked more for the benefit of his country, and in no work was his mind more single-minded desire for disseminating that which he believed to be valuable knowledge. Those who knew him personally, or from correspondence, allow that he was a kind and benevolent man.

BARKER, ROBERT, born at Kells, in the county of Meath, Ireland, was the inventor and patentee of panoramas. He practised originally as a portrait painter in Dublin and in Edinburgh. The first picture of the kind which he painted was a view of Edinburgh, exhibited in Edinburgh in 1788, and in London in 1789, but with indifferent success. His second painting was a view of London from the Althoen Mills, and it was exhibited, with complete success, in London, at the Leicester Square, and afterwards in Germany. He built, and opened in 1793, with a panorama of Spithedam, the present panorama exhibition-rooms in Leicester Square, now the property of his son; and a second was erected in the description of painting. He was assisted in many of his panoramas by his son, and by R. R. Realage, R.A., from whose sketches most of his foreign views were painted: as Rome, the Bay of Naples, Gibraltar, and the Bay of Algeirs. Nelson's battles of Trafalgar and Copenhagen were also among his most popular panoramas. He died in London, in 1806.

BARLOW, FRANCIS, a native of Lincolnsire, in which county he was born, in the second part of the eighteenth century, about 1726. He was instructed by a portrait painter, but he preferred landscapes, birds, fishes, and animals, in which he excelled. He was particularly excellent in birds of prey, which he painted on the wing with great skill, particularly in drawing. As a colourist he was indifferent; on which account many of his works appear much better in engravings than as pictures. John Overton published 12 prints by Holms, after Barlow, representing various sports, of hunting, shooting, &c., and other field sports. Barlow was also engraved: he etched some of the plates of his own illustrations to Ogilby's translation of Æsop's Fables, and also part of the plates in the folio book of poems entitled Theopha, published 1737. There are many engravings of birds by Barlow, engraved by W. Fieldin: 'Diversa Sspecies studioissimae ad vitam delineatae per Fras. Barlow, ingeniosissimam Anglum Pictorem. Gull. Fieldin excedit, 165.'

Once, when sketching in Scotland, he saw an eagle endeavouring to fly away with a cat in its talons; but the cat struggled so much, that eagle and cat both fell to the ground together: this circumstance led him to engrave a plate of an eagle seizing a cat. There is a copious list of his prints in Heineken's Dictionary.

Barlow was employed by several noblemen and gentlemen to paint ceilings, with hawking subjects, or other scenes of birds on the wing: the birds were painted on the clear sky. He painted also a few portraits, among them a half-length of General Monk, first Duke of Albemarle. Though he was very much employed, and had a considerable sum of money left by him, a friend, he died poor in 1792.

(See Essay on John, 1706; Walpole, Anecdotcs of Painting; Strutt, Dictionary of Engravers; Heineken, Dictionnaire des Artistes, &c.)

BARRETT, GEORGE, an Irish landscape painter of great celebrity in his time. He was born at Dublin in 1732, and commenced his studies under the tuition of John Mack, of the name of Silcock. His first landscapes were painted from the estate of the Earl of Powerscourt near Dublin; and the Earl was his first patron. He gained a 60-guineas premium from the Society of Arts in London, for the fourth premium given by that Society for landscape. He was one of the original members of the Royal Academy, founded in 1768, and towards the close of his life he was Master Painter to Chelsea Hospital, an appointment which he procured through his friend Burke. He died at Playford in 1784.

Barrett's landscapes are bold and natural in design, but his colouring is somewhat peculiar and heavy. He painted also in water-colours, and executed a few etchings.

(Edwards, Anecdotes of Painting, &c; Pilkington, Dictionary of Painters.)

BARRY, LODOWICK, was the author of a comedy called 'Ram-Alley, or Merry Tricks,' which was first printed in 1611, again in 1636, and will be found in the successive editions of Dodsley's 'The Plays.' The character of Barry was that of the incident, and for spirit and humour in dialogue and in character, it is one of the best of our old English dramas. In regard to the author nothing is known with certainty. He is said however to have been an Irish gentleman; and the editors of the 'Biographia Britannica' have given his name a place in their work for the purpose of contradicting Anthony Wood, who insisted on making him a Lord Barry.

BARTAN, THOMAS, P.C., was born in 1655. As an engraver he obtained a great reputation, more however from the subject...
and the number of his prints than for any particular excellence of execution. He was the scholar of Nicholas Poussin, from whom he probably, in some degree, derived his great love of the antique in art. As a pupil he differed very much from his master beyond copying, in which he was so excellent, that even Poussin himself had difficulty in distinguishing between his own pictures and the copies made of them by Bartoli. Bartoli was a master of the art of etching, and though technically his prints have little excellence, they are in most cases true to their originals. His prints, mostly etchings, which amount to many hundreds, are chiefly from ancient basi-reliefs or paintings in the ruins in or about Roman and Etruscan cities. He is also a printer, and established a business in Rome, which was continued after his death by his son Francesco Bartoli. P. S. Bartoli died in 1700.

Geckelmann was a great admirer of his works, and recommends young artists to study them in order to acquire a proper appreciation of ancient art. They are free, but slightly executed, and all in the same style. The following are among the principal collections executed by Bartoli:—Admiranda Romanarum Antiquitatum ac Vetas. Sculpturae Vestigia, with remarks by Bellori; Romanae Magnitudinis Monumenta; Vetere Arcus Augustorum triumpha insignia, ex reliquis quae Romae adhuc superantur; Le Picturc Antiquae Urbis et Urbis Nova; Gli Antichi Sepolcri, overo Mauoeoli Romani ed Etruschi trovati in Roma; and Recueil de Peintures Antiques imitées fidèlement, for the colours and for the traits, d'après les dessins colorés fait au P. S. Bartoli, Paris, 3d vol., 1710, 1712, 1713. The first work of the third volume, published in 1752, contains an additional plate not found in the older editions.

In 1781 he was appointed keeper of the prints of the royal library. In 1791 he was appointed keeper of the prints of the royal library, which led eventually to the publication of his well known work Le Peintre-Graveur, in 21 vols., 1795-1805, the description of which was commenced in 1792, but not finished until 1801. This work contains 100 plates of Italian paintings, of which 50 are engraved by Bartoli himself, and 50 by his son. The work is completed in two volumes, the first published in 1782, and the second in 1790.

The plates of Bartoli's work were engraved by the principal engravers of Europe, and to which he now owes his reputation, though he be the author of several similar works on a smaller scale, but they are all more descriptive than critical. There is also a catalogue of Bartoli's engravings published in 1782, which contains 100 plates of Italian paintings, of which 50 are engraved by Bartoli himself, and 50 by his son. The work is completed in two volumes, the first published in 1782, and the second in 1790.

179

car and Pars, resting on chalk; the coal-basin of South Wales, resting on old red-sandstone, and, in a larger sense, the European basins between the Ural, the Scandinavian chains, and the Pyrenees, Alpæ, &c. Some of these basins are due to the war of deposition; others have acquired their configuration from elevations and depressions of particular geographical areas.

BASSO DI CAMER'A, a double-bass, or contrabass, refers to c. 1824, and that may not in compass, and thus needed to small or private rooms. The dimensions of the body of this instrument are as follows:

---

Hence, and by referring to the article DOUBLE-BASS, it will be seen that this new instrument has a great advantage, in respect to compass, over the other; and in quality of tone is it hardly inferior, in modern and powerful music, thought it is power not enough designed to supersede, or even to be used as a substitute for, the double-bass in the full orchestra.

The Basso di Camera, in its present perfect state, owes its birth to Mr. T. W. Hancock, of Coventry Street, Haymarket, and was first introduced November 14, 1844, in Queen Square, Bloomsbury, at the residence of an excellent dilettante, to whose active research and zealous encouragement modern chamber music is more indebted than to any individual of the present age. Indeed, it is but justice to say that the two eminent composers who first in mind are to call attention to Mozart's operas, by having, early in the present century, had two or three of them privately got up by a few musical friends; from which time the fame of those unrivalled works gradually expanded, till the greatest of them, the Don Giovanni, was in 1817 produced at the King's Theatre, when, and not till then, the reputation of its author may truly be said to have reached its scene.

BASTARDY. Under the act of Elizabeth and later acts of parliament, down to the passing of the Poor Law amendment act in 1834, the usual practice was for the mother to apply for relief to the parish officers, by whom she was examined before the magistrates in petty session to be interrogated respecting herself and the child. If a bastard was then made, and the reputed father was ordered to contribute a weekly payment, or was bound to indemnify the parish against the future expenses of maintenance. In form, the proceeding was against the putative father for the indemnification of the parish; but in substance it was a proceeding of the mother against the putative father, the benefit of which accrued to her, and to which the parish was little more than a nominal party, except when it made good the father's default. It was in truth an action on the part of the mother against the putative father, for a contribution towards the expenses of their child, in which by a fiction of law, the parish was plaintiff.

(On the law concerning the maintenance of bastards, by the Poor Law Commissioners. Earl, paper. No. 31, Session of 1831.)

In this state of things, the Commissioners of Poor Law Inquiry (1834) recommended that the mother of a bastard should be rendered liable for its maintenance, but that she should be exempted from the punishment under 30 Geo. III. c. 51, and that all men changing the putative father should be repealed. The Bill for amending the Poor Law, brought in in 1834, as it ultimately passed (4th and 5th Will. IV. c. 76, §§ 72-76), enacted that the parish might apply for an order upon the putative father, but this was to be done at the quarter sessions instead of the petty sessions; and corroborative evidence was required; and other difficulties and onerous conditions were thrown in the way, which showed that the object of the Legislature was to impede the application at the quarter sessions. The number of bastards affiliated in England and Wales, in the years ending respectively 25th of March, 1835 and 1836, was 12,381 and 9,686. The practice of affiliation was therefore rapidly diminishing under the Poor Law Amendment Act 1834; and was alleged to be an act of justice, as the putative father was not punished, while the consequences fell solely upon the woman. In 1839, therefore, an act was passed (2 & 3 Vict. c. 88) which transferred the power of making orders in bastardy from the quarter sessions to any two justices in quarter sessions, and that the same orders might be made at the petty sessions, and in cases of dispute, in the court of the proceeding, and a mere screen to the woman. (Report of the Poor Law Commissioners, Jan. 31st, 1844.) The law respecting bastardy has been still more recently the subject of legislation, and by 7 & 8 Vict. c. 101, the principle of charging the putative father with liability different in that of any previous law on the subject. Formerly the remedy was intended exclusively for the parish: now the mother alone can obtain it. Formerly the chargeability of the child, either in fact or in prospect, was the ground of the remedy: now the actual or probable chargeability of the child is made wholly immaterial. (Official Circular, No. 59, Oct. 1, 1844.) The officers of all parishes and unions are deprived of the power of applying for orders of affiliation with regard to illegitimate children, and the mother alone is entitled to apply, at the petty sessions, for such order; but in case of the death or incapacity of the mother, the guardians of unions, or if there are no guardians the overseers, may apply for the same purpose. Such orders cannot apply for petty sessions, and payments are to be made to some person appointed by the courts to have the custody of the child, and not to the parish officers; and such person is to receive the child on the condition that it is not to be chargeable. Parish officers are guilty of misapplication for endeavouring to promote the interest of a mother of a bastard, by threats or promises respecting any application to be made for maintenance. The mother of a bastard may summon the putative father before the petty sessions within twelve months after the birth of the child, for the purpose of obtaining the order of maintenance, or if the child has been put to her in respect of such child. The justices may then make an order on the putative father for maintenance of the child and other costs, and enforce the same by distress and commitment; but not more than thirteen weeks' arrears can be claimed. The sum paid for maintenance is to be paid to the mother, and if she neglect or desert her offspring she may be punished under the Vagrancy act (5 Geo. IV. c. 89). While unmarried or a widow, the mother is liable for the maintenance of the child until it is married; having the care of a bastard child under an order of maintenance, who maltreats it, or misapplies money paid by the putative father for its support, is liable to a penalty of 10l. on conviction before two justices in quarter sessions. The putative father is liable at the quarter sessions, as under the old law. All orders for the maintenance of a bastard cease after it has attained the age of thirteen, or on the marriage of the mother. Existing orders are to continue, but those made before August 14th, 1834, are to cease on the 1st January, 1849.

In the Savings Bank Act (7 & 8 Vict. c. 83) there is a clause under which the deposits of illegitimate persons who die intestate may be paid to their heirs, as if they had been legitimate; but in other respects the law relating to the succession and inheritance of bastards remains the same. By 6 Wm. IV. c. 22, the incapacity of bastards in England to dispose of their moveable estates by will was removed.

The late Mr. Rickman was the first who attempted to ascertain the number of illegitimate births in England. During the progress of the census of 1831, he obtained from the ministers of churches and chapels the number of bastards born in their parishes or chapels in 1830. The number returned was 20,096. To correct the Registration act (2 & 3 Will. IV. c. 86) no specific reference is made to illegitimate children, but the penalty for making a false statement, combined with the local knowledge of the registrars, in most cases prevents such children being registered as born in wedlock. Still there is no question that the registration *is* giving something less than the real number of illegitimate children born. Of the births which escape the vigilance of the registrars, it is most probable that the proportion of those which are illegitimate is greater than they are in proportion to the whole number of the births.
than for births in wedlock. In Saxony the proportion of stillborn children to 10,000 illegitimate births is 816, in 10,000 others 464; age however may be the number of illegitimate births as they appear on the face of the register, it may safely be assumed that they are below the actual number. In the Registrar-General's fifth report (p. 10), it was stated that in 1841, 248,000 registered births in England 15,830, or 1 in 16, were illegitimate. The Sixth Annual Report issued in February, 1845, gives the total number of illegitimate births registered in England and Wales in 1841 and 1842. In 1841 the number was 36,294, and 54,766 in 1842, 53,729 births, who in the returns on which reliance was formerly placed gave 1 in 20. In 1842 the number of illegitimate born boys was 17,810, and of females 16,986, or 21 boys to 20 girls: the proportion of other births. The number of illegitimate females in England and Wales, between the ages of 15 and 45, was about 3,811,654 in 1841. Of these it is estimated by the Registrar-General, that 1,738,576 were married and gave birth in the above year to 469,964 children, and 2,078,078 were unmarried and gave birth to 35,924. The children born in wedlock as 28 to 100 of the married women, and the illegitimate children were as 1 to 7 to 100 of the unmarried women.

Before any certain inference can be drawn as to the state of manners in different districts, the relative number of married and unmarried women should be ascertained; but there are no means of arriving at this fact. The average number of illegitimate and other births for the whole of England is 67; but in Cumberland it is 114 per cent., and in some districts 1 to 12 to 1 to 100, which latter is one of the several proportions that exist at Wigan, in Lancashire. Nearly all the English towns are below the average of England. In France, Sweden, and most parts of the continent, the towns are above the average of the country.

The tables in the Sixth Report of the Registrar-General show that the highest proportion of illegitimate births is in Cumberland, Nottingham, Lancashire, Herefordshire, Norfolk, Cheshire, and the lowest proportion is in Middlesex, Cornwall, Surrey, Devon, and Monmouth, and Westmorland.

The table showing the proportion for each county would occupy too much space; but grouping the counties into the following divisions, the results are as follows:

The proportion of illegitimate births in 100 births in parts of the metropolis and in towns, in 1841, was as follows:—In Rochester, St. Luke's (Middlesex), Hackney, the Strand (Westminster), it is under 20 per cent.; in Bethnal Green, Islington, St. Savour's and St. Olave's, Bermondsey, St. George's, Soho, it does not exceed 21; in St. George's, in the East, Clerkenwell, Shoreditch, Lambeth, Greenwich, and Holborn, it is under 3; in Newington, St. George's, Hanover Square, Kensington, Chelsea, Cumberwell, St. Pancras, it does not exceed 21; in Liverpool, it is 30; in Hull, 38; in Birmingham, and in the city of Westminster, and in Whitechapel, London, it is 4; in Plymouth, 4; in Winchester and Bristol, 4; in Oxford, 4; in Derby, 4; in Cheltenham, 4; in Sheffield, 5; in Northampton, 5; in Leeds, 5; in Chichester and Wakefield, it is 7; in Manchester, who he makes in the following chapter, speaking of the statue of the god himself, might have considerable weight in controverting the opinion of Heyne: in there says—Bathylcles did not make the statue itself; it is made by his nephew, and made with the ideas of Juno, and is clearly opposed to the period of Bathylcles. From his substantially agreeing with Heyne, places Bathylcles in the 23d Olympiad, contemporary with Archilochus. This was at the close of the second Messenian war, which has much in its favour in the ideas of Aristotle, the general of the Messenians, plundered Amyclae; the Spartans therefore, at the successful completion of the war, might naturally make some votive demonstration from the spoils, to conclude the god of Amyclae, and average the
outrage upon his shrine or temple. Yet why should Pausanias not mention such a circumstance; or why was there no allusion to such trophies in the designs upon the throne? These questions present difficulties, yet probably appears rather to favor the ideas of the column. For the earth wind is about 665 a.c., is not so early that it could not have been resent in the opinion of Pausanias when compared with the period of the statue of the god itself; Lydia was also familiar then with the peculiar name of the Lydian artists. But in the later period, about 665 a.c., Lacedaemon, as well as other towns of the Peloponnesus, had its own artists of name. On the top of the throne Bat- thycles represented himself and his assistants. Quaternary de Lyssicrates, a master, had given a view of the god and his throne, designed from the description of Pausanias.

The Batthycles who left a cup for the wisest man was a different person; he was of Arcadia, and lived certainly in the time of Solon, but it does not follow that he was an artist because he made a bequest of a cup. Voss and Sillig suppose that Batthycles the sculptor lived even after the time of Solon, and that the presence of himself and assistants in Lacedaemon is accounted for by the Persian conquest of Lydia. (Pausanias, iii. 18 and 19, iv. 18; Heyne, Antiquarische Aufsätze; Thiersch, Epochen der Bildenden-kunst unter den Griechen, 1829; Sillig, Catalogo Artificum.)

To the top of the cell, or kroie, was the most distinguished of the eighteenth century, was born at Lecce in 1708. His father was a goldsmith, and Pompeo had thus an early opportunity of displaying his ability for design. He established himself very early in Rome, where he was a pupil of Belzoni, is presented to us not by copying celebrated pictures, but in a few years he obtained the first name in Rome, and with the exception of Mengs, lived there until his death, for forty years, without a rival: he died in 1787.

Baton was equally excellent in portrait and history. His historical works are chiefly scriptural and from the lives of the saints; he painted also many single pictures of saints of both sexes. His portraits, which are admirably modelled, are known to be (1) the grandeur of the Roman Emperors, that set themselves off in full length. He excelled in drawing, in tone, and in colour; his execution was also often extremely elaborate; but in composition he was considered inferior to Mengs, though equal to him in expression.

He was less philosophical also in his subjects than Mengs. His manner is that of a Batoni; he was an academical, and Batoni has sometimes been honoured with a title bestowed more generally upon Maratta, that of the School of Batoni.

Several cities of Italy possess altar-pieces by Batoni, and there are also many of his works in Germany and other foreign countries; some of his best works are at Lisbon and at St. Petersburg. His principal works at Rome are the Fall of Simon Magnus, now in the church of Santa Maria degli Angeli at Rome, but painted originally to be copied in mosaic for one of the altars of St. Peter's; the mosaic has never been executed. Batoni was a Cavalier and a Ritter of the order of Maria Theresia. His friend Car. O. Boni wrote a eulogy upon him shortly after his death: 'Elogio di Pompeo Girolamo Batoni,' Rome, 1787.

(Batoni, Geschichte der Malerkunst, &c.; Lanz, Storia Pintori, &c.)

BATRACHIDA, FOSSIL. The number of fossil Reptilia referrible to this division is gradually enlarging, though still very small. To the anourous Batrachians we must, with Jüger and Professor Owen, refer the Labyrinthodonta of the new researches discovered in the Biederwermberg (including perhaps the Cheirotheria whose foot-prints ornament the red-sandstones of England and Germany); while the territory fossil of Oenningen (which Scheuchzer imagined to be a human foot) is determined by Cuvier to be analogous to the Neot of Europe. These, and the Reptiles which inhabit the earth period, Remains of frogs and salamanders occur in the tertiary brown coals of the Rhine Valley.

BATRACHUS, an architect and sculptor of Laconia, who lived in the time of Augustus, among the friends of that author. Batrachus tells a story of Batrachus and his fellow-countryman Saurus. He says—Being very rich, they built at their own cost two temples to Jupiter and Juno at Rome, enclosed by the porticoes of Octavia, hoping for an inscription; but this being refused them, they introduced their names in another manner, by carving a lizard (Saurus) and a frog (Batrachus) in the centre of the Ionic capitals in each volute of the column. The same is still at Rome, in the church of San Lorenzo, a column with an Ionic capital of this description, in which the reptiles are well executed. The story is improbable, and perhaps originated in the peculiar name of the architects derived their names from the reptiles, rather than the reptiles their imago from the names of the architects. (Pliny, Hist. Nat. xxxvi. 4. 11; Winkelsmann, Werke, i. 573; Thiersch, Epochen der Bildenden-kunst unter den Griechen, 1829.)

An electrical battery is a number of cylindrical vessels of glass, each precisely similar to the usual Leyden jar, the open top being covered by a plate of wood, into which is screwed the foot of a brass pillar which terminates at the top with a ball of the same metal, and at bottom with a chain which descends to the lower part of the jar inside; and both the inside and outside of each jar are lined with tin-foil to within two or three inches of the top. These are contained within a wooden box, whose interior is lined with tin-foil; a piece of wire passes through the foil and the side of the box, and carries on the exterior of the latter a ring, to which should be affixed a chain descending to the table or ground.

The parties to be electrified were perforated in order that it may receive the brass rod or system of bars by which the top of all the jars are to be connected together; the rods are terminated with brass balls, and one of these, or a ball at the upper extremity of a pillar forming part of the conductors, is brought to the inside of the battery when the battery is to be charged. This kind of battery was first proposed by Gralath, a German, in 1747; and the manner of charging and of discharging it differs in no respect from the manner of performing the like operations with a single jar.

The quantity of electricity in a jar or battery is directly proportional to the superficies of the coating and to the degree of intensity; and the latter is in the inverse ratio of the distance of the particles. The particles of the particular battery which receive electricity, by which, the machine are excited, in the conductor and, with that, on the interior surfaces of the jars, exert, through the glass, attractive powers upon the resinous or negative electricity which, by that attraction, are brought from the earth to the exterior surfaces of the jars: this accumulation within the jars continues till the repulsive powers of the particles are great enough to counteract the power of the machine to supply fluid through the conductor: the charge of electricity is then considered as complete. The quantity of electricity estimated by the quantity of metallic wire which it will ignite or melt. The battery consisting of 100 jars, which was made by Cutbush for the museum at Haarlem, and which contained 650 square inches of coating, ignited 656 inches of iron wire 40 inches in diameter.

The batteries in which electricity is excited by the chemical action of a fluid upon a metal, or of two metals upon one another, are called galvanic or voltaic, and are of various kinds: it is intended here to describe only those which are most frequently used.

The simplest combination which can be formed for the production of an electrical current by such means is that of a plate of zinc and a plate of copper placed generally, in vertical positions and parallel to one another in a vessel containing a dilute acid, the upper edges of the metals being connected by a copper wire. In this state a current of positive electricity passes from the zinc, through the acid, to the copper, and from the latter, along the wire to the zinc: at the same time a current of negative electricity passes from the zinc, along the wire, to the copper, and from thence, through the acid, to the zinc. It is evident that the quantity of fluid current of this kind in this apparatus is equal to the superficies on which the acid can act; and an apparatus designed a battery, which may be said to consist of two plates only, one of zinc and the other of copper, was executed for the London Institution. Each plate is 50 feet long and 6 feet wide, and the whole circuit is 300 square feet, or the equivalent of 5000 cubic feet of wood, so as to leave everywhere an interval between the two metals: in that interval rope-bands of horse-hair pass round with the coils so as to keep the metals asunder. A cylindrical vessel containing this battery, it is said, is fitted to use, the coils of metal are lowered by machinery into the vessel.
But it is more convenient, for the purpose of obtaining the electrical fluids in abundance, to combine together a considerable number of small plates of zinc and copper, alternately, with the acid between them; and such a pile is called the voltaic pile; it is a battery of this kind. Under Galvani and Volta (P. C.) are explanations of the electrical action, and we here merely describe the construction of the pile. A circular plate of zinc, z, usually about 1½ inch diameter and ⅛ inch thick, is laid upon and generally soldered to a very thin plate of copper, c, of equal diameter; and any convenient number of these are placed above one another, with the copper plates forming the anode, and the zinc plates forming the cathode, so that every two compound plates is a circular piece of paper, p, or cloth moistened with diluted sulphuric acid; and the whole column or pile is made to preserve a vertical position by being formed within three pillars of glass or baked wood, which are connected together by having their extremities inserted in boards, of which the lower one serves as a base for the column.

The paper or cloth should be rather less in diameter than the plates of metal; and no moisture should be allowed to escape over the edges of the plates.

The uppermost plate of zinc attracts the positive electricity from the copper below it, and this continually receives a supply from the earth through the table, or the base of the pile; the quantity thus attracted is conveyed to the copper plate immediately above, through the moistened cloth, and so on; the zinc in the second plate attracts electricity from the copper below it, and, at the same time, receives that which is transmitted from the latter to the zinc in the lowest plate. Thus the quantity of positive electricity in the zinc of the second plate becomes nearly twice as great as that which is in the lowest plate; and the process continuing, the quantity in the zinc of each plate above may be conceived to be such a multiple of that which is in the lowest plate as is expressed by the number of the compound plate from the bottom of the pile. There is consequently obtained a current of positive electricity passing upwards from the zinc, through the acid, to the copper; and if a copper wire be made to pass from the top of the uppermost zinc plate to the copper in the lowest plate, the same current will return downwards, so that a circulation of the fluid will continue till the energy of the pile is exhausted. At the same time there is a current of negative electricity passing down the plate from the copper, through the acid, to the zinc, and this current is directed upwards along the pile.

If a second pile be formed, the plates in it may be placed in a reverse order, the copper side above and the zinc side below; if a third pile be formed, the order may be the same as in the first; it is found that the same is the case with the second; and so on; under the same conditions; the zinc of the second; another metal wire passes from the copper at the top of the second to the zinc at the top of the third, and so on.

When a wire connects the opposite ends of one pile, or of a system of piles, the circuit is said to be complete: it is said to be broken if there are two separate wires, one proceeding from the copper at bottom, and the other from the zinc at the top. If an animal body is connected with the farther extremities of the wires it would complete the circuit, and experience shocks.

The opposite extremities of the pile, or of the wires which are in contact with them, are called the poles of the battery. As the current of positive electricity seems to issue from the zinc at the top of the pile, that extremity is called the positive pole of the battery; at the same time the negative electricity seems to issue from the copper at the bottom, and therefore the zinc in the bottom plate is called the negative pole. These designations are reversed when a single pair of plates separated by an acid is mentioned. In that case, since the positive electricity passes from the zinc plate, through the acid, to the copper plate, and that the wire passes through the zinc from the copper plate to that of the zinc plate; it is evident that the positive electricity will flow from the copper, and therefore the copper is the positive pole of the combination; the negative electricity flowing at the same time along the wire, from the zinc, the latter is the negative pole.

That which, till lately, was most generally used is called the trough-battery, because the acid is contained in cells formed in a rectangular trough, usually of glazed earthenware, by nine or more parallel partitions of the trough; and permit no communication between one cell and another.

As many pairs of plates, zinc and copper, of equal surface, as there are partitions, are provided; the two plates of each pair are soldered or fastened together at their upper extremities, so that they may be parallel to one another; and are united together by a rod of wood, so that they may be placed into or removed from the cells. The bridges of connections between the zinc and copper plates stand directly over the partitions, so that there is a copper and a zinc plate in each separate cell, except at one extremity of each trough, in which, till two troughs are connected together, the cell is only a zinc plate. When one trough is to be connected with another, it is first a rod of wood, the plate a, soldered at the top of a zinc plate, is bent and made to enter the cell B, containing only a zinc plate at one end of the preceding trough. In order to form the complete circuit, one extremity of a wire is made to enter the cell A, for example, and the other extremity of this wire is brought to the opposite end of the trough, or series of troughs, where it is placed in contact with the copper slip, as a: the positive current then flows along the wire from the extremity first mentioned to the other.

That which has been just described is designated Mr. Children's battery, and Dr. Wellaston proposed, as an improvement upon it, to have in each cell a zinc plate between two of copper, for thus both surfaces of each zinc plate would become conductors when in production of the current, and the power of the battery would be increased by one half. The battery at the Royal Institution is of Mr. Children's kind; it contains 2000 pairs of plates, each 8 inches long and 4 inches deep, and with it Sir Humphry Davy made his principal discoveries.

The battery invented by Professor Daniel consists of any number of cylindrical vessels of copper, open at the top, about 10 inches high and 3 inches in diameter, and containing a saturated solution of sulphiure of copper; the external surface of each may be painted, but the interior, which alone is efficient in producing electricity, is made bright. On the top of each cylinder is placed a hemispherical cover, a, in which is the direction of the axis of the cylinder, a is a perforation above an inch in diameter; and to its base is attached a short tube b of copper, less in diameter than the cylinder, and carrying at its lower extremity an annular plate c of copper, in which are pierced several small holes. When the wooden cover is placed on the cylinder, its base rests on the top of the latter; and the part of the cylinder between the short tube and the annular plate is filled with crystals or pieces of sulphate of copper, which, gradually dissolving, furnish the strength of the solution in the lower part of the cylinder.

To the interior of the short tube is affixed one end of a piece of ox gullet, d, about the same length as the copper cylinder, and having its lower extremity tied so that the whole forms a mercurial battery; this is to contain the diluted sulphuric acid (eight parts water to one of acid). A rod of zinc, z, about the same length as the cylinder, an inch in diameter, and terminating at the upper extremity with a ball, is passed through the part of the wood, down to the interior of the membrane, so that its shoulder rests on the top of the wood; the surface of the zinc being previously covered
with an amalgam of mercury. Instead of a membrane, a bag of paper or canvas, or a vessel of porous earthenware, may be used.

If now, a connection, by means of a wire or metallic rod, were made between the ball at the foot of the zinc rod and the top of a stem which rises from one side of the copper cylinder, the zinc will be corroded by the sulphuric acid and the electric fluid will pass to the copper through the acid, the membrane and the solution in the cylinder. [VOLTAIRE, P.C.]

The battery invented by Mr. Groves consists of several porous vessels containing strong nitric acid, and, in each, a rod or plate of platinum; each of these vessels is placed between two porous plates of copper and zinc, or of sulphuric or muriatic acid. The rod of platinum holds the place of the plate of copper in Children's battery and constitutes the negative pole of each combination; the zinc plate being the positive pole.

The battery used first by Professor Whatatstosko for his electrical telegraph was formed nearly on the same principle as that of Mr. Daniel. A small outer vessel contained a solution of sulphate of copper, together with the plate of copper which formed the negative pole; within this, a small porous cell contained dilute sulphuric acid, and at the bottom was an amalgam of zinc and mercury, which constituted the positive pole. An electro-magnetic apparatus is now employed for the telegraph.

BATTUS, the suggested title proposed by Dalman to replace the name Agnostus, which Brongniart gave to some minute trilobate Crustacea which occur in the Silurian limestones of Norway, Wales, etc.

BAUMANNSHOOLE, one of the bone-caverns in Frainomia (Buckland, Strigilus Tretracum.)

BAYSE. [GROUSE, P.C.]

BAZHENOV, VASSILI IVANOVIITCH, an architect distinguished among the native artists of Russia, and first vice-president of the Academy of Fine Arts at St. Petersburg, was born at Moscow, March 1 (18), 1737. While yet a boy, he is said to have manifested a decided taste for drawing houses and buildings, which was his favourite amusement, and in which he endeavoured to improve himself by studying the churches, monasteries, and other public buildings of that ancient capital, his earnestness in such task making him in lieu of practical method. In 1751 he began to attend the School of Architecture at Moscow, which was then under the direction of Prince Uchtomsky, who in 1778 placed him in the chair of a recently established Moscow University, in order that he might study modern languages. Three years afterwards, on the Academy of Fine Arts being opened at St. Petersburg, and youth who gave indications of superior talent being encouraged, Bazhenov was in March, 1773, awarded a travelling scholarship. After pursuing his studies there, under Tcherepanovski, with distinguished success, he was sent to Paris in 1781, where he became the pupil of Duval, and would have obtained the gold medal of the Institute of France, but for his belonging to the Greek Church, wherefore in lieu of it he was rewarded by a diploma of merit, signed by the three eminent architects, Leraldi, Buffon, and Gabriel. Proud of his having obtained such distinction as had never before been conferred on any Russian, the St. Petersburg Academy bestowed on him the degree of A'djunct, and sent him forthwith (October, 1782) to Rome. While in Italy he was elected member of the Academy of St. Luke, and of those of Florence and Bologna.

On his return to St. Petersburg, in 1785, he was taken into the immediate service of the Empress Catherine, who found him constant employment in various architectural projects and schemes which she had conceived, and among others that of entirely rebuilding the Kremlin at Moscow, clearing the whole site, and erecting upon it a palace that should surpass every monument of ancient or modern times. In magnitude it certainly would have done so, for the façade would have been upwards of four thousand feet in extent, and some idea may form of the pomp and magnificence con- sideyed by Catherine and her architect, from the estimate for the state staircase alone, which was to be entirely of Italian marbles, amounting to five million rubles. Even the model itself — which is still preserved in the Kremlin — cost no less than two hundred rubles. Never had such elaborate plans and preparations been had, and the first stone of the intended edifice was laid with great solemnity on the 15th of June, 1778, on which occasion Bazhenov delivered an oration, composed by Sumanov (Semianov, P.C.) — the works were shortly afterwards interrupted, and never resumed.

Still, if greatly diminished in consequence of his plans not being carried into execution, the fame attending so vast a project is not inconsiderable of itself; — as is evident from the renown which one great English architect has derived from what, but for circumstances, would have been his greatest work; — therefore, alike in fate, Inigo Jones' Whitehall and Bazhenov's Kremlin may be allowed to share alike in fame.

In 1770 he began for the Empress a summer palace, in the Gothic style, at Tsarskito, but Catherine, who in the meantime had withdrawn her favour from Bazhenov, was so far from being satisfied with the building, that she afterwards ordered it to be completely altered by Kozakov. Her successor, the Empress Catherine II., lavished many honours upon him, and employed him to erect the palace at Gatuchina, that at Pavlovsky, and several government buildings at Crossow. But the most magnificent structure which he executed for the Empress Paul was the St. Michael or Marlbo Palace at St. Petersburg, the vast and massive pile within whose walls the unfortunate Paul was assassinated, and which, judging from the very minute description given of it by Kotzebue, must originally have been most sumptuous; but all its internal splendour has now disappeared, having been converted into a military school for engineers. Bazhenov is also said to have been associated with Voronikin (Voronikis, P.C.) in building the halls at St. Petersburg. Bazhenov died of paralysis, at St. Petersburg, August 2 (4), 1798. He left a great number of architectural drawings and designs, which the emperor ordered to be published, but Paul's own death, shortly afterwards, frustrated that intention. A memoir of himself has been given by a Russian translation of Vitruvius, 1790-97, in four volumes 4to.

(Snegirev, Slovov Rashka Pisatel.)

BEACHES, RAISED, a term introduced into modern geology to characterize a very numerous class of gravelly, sandy, and shelly deposits, which have been dry land in very modern geological periods. It is scarcely possible to assign exactly the limits of these formations, even by the aid of the geological enumation of what are called the drift; for the present, the beaches contain only species now living in the adjoining sea, others include one or more extinct species, and thus conduct by insensible gradations from the almost modern shell-beds of the raised shores of the Firth and Clyde and the variously elevated shell accumulations of Uddewall in other points of Sweden, to the still richer and more antient (though still to be called Newer Pleistocene deposits of Sicily. The term Pleistocene (most recent), which has come into use, meets this difficulty but fails to place fixed feet only within the epochal line, instead of the soft gradations of long periods which really appear in nature. Nearly all the British, Irish, and European shores furnish examples in abundance: as the shores of the Firth and Clyde, the coast of Cornwall and Devon, of Yorkshire, Normandy, Sweden, and the Mediterranean.

BEALE, MARY, an English portrait painter of the seventeenth century, about whom Vertue collected some interesting details from some journals on pocket-books kept by her husband, of which she saw seven. She was the daughter of the Rev. Mr. Crudock, minister of Walton-upon-Thames, and was apparently taught painting by Sir Peter Lely. The first date then in these pocket-books is 1671; but Lely's visits to her, and his praises of her copies from Correggio and Vandyke, are noticed. In the same year she painted portraits of the Bishop of Chester, Lord and Lady Comyn, and Dr. Sydenham, besides others; and she received in that year, for painting the portrait of Sir Charles Sedley, 200l.

Sir Peter Lely painted for Mr. Beale portraits of Dr. Tillo-ton and Dr. Stillingfleet, in Mr. Beale's house, in the presence of his wife, in order, probably, that Mrs. Beale might see the method of painting. Sir Peter Lely's method is said to have been as follows: he made a speedy preparation of the ground, believing for the watercolours 30s., of which he took 281. 19s. in lakes and ultra-marine. In 1674 Mrs. Beale made 216l. 6s. by her paintings. It seems a Mr. Manby painted some landscape backgrounds in some of her portraits, for which he was paid 20l. 10s. In 1671 she was paid two ounces of lake, and one and a half of pink, for a landscape to the portrait of the Countess of Clare. In 1677 she received 450l. for picture; a very large amount. And among the portraits of this year were those of Ludwig, and many others of the nobility. She was paid 5l. for a head, and 10l. for a half-length in oil. In 1681 Dr.
Prince Doria. He executed also some of the designs of the foot-pavement of the cathedral of Siena; which work was commenced by Duccio di Buoninsegna, according to Vasari, but in which, as Vasari himself was not, he did not assist. The designs of the foot-pavement are a species of ancient outlines of the figures are cut into the stone, and filled in afterwards with a black cement. Those of Beccafumi have been engraved by Andreani and Cosati. Beccafumi cut the slab of marble, and the engravers completed the work.

BECCHERA, a genus of fossil plants proposed by Otto Sternberg. Bechersia charafornica occurs in the strata of Calabria, and in the possessor of this genus. It is a woodcut, with the prints after his designs by other masters, are enumerated by Heineken.

Vasari, Vita de' Pittori, etc.; Lanzi, Storia Pictoria, etc.; Huyghens, Discorsi sopra le Arti, etc.; Romani, Italianische Forschungen; Brulliot, Dictionnaire des Nouveaux, etc.,

**BECKERFORD, WILLIAM,** celebrated for his great wealth, talents, and eccentricities, was the only legitimate child of Alderman Becket Ford, of London, who died on the 21st of June, 1770, in his second majority, within a month after his famous exhibition at court, when, after presenting the city address to George III., and having received his majesty's answer, he made the reply which may be read on his monument. He was also a most munificent donor to the British national collection of pictures. He was married in the establishment of the National Gallery; in furtherance of which he promised to contribute part of his own collection at Cocketon Hall: he accordingly presented to the National Gallery sixteen paintings, chiefly landscapes—a landscape and figures by N. Poussin; Hagar and the Angel, Nascius and Edojo, the Death of Procris, and a study of trees by Claude; a view of Venice by Canaletto; a large landscape and figures by Rubens; a landscape and figures by Both, called Morning; a landscape, called the Return of the Arms of the A. of Bourdon; the Villa of Mecenas, and the Niobe of Wilson; a portrait of a Jew, and a sketch of the Descent from the Cross, by Rembrandt; a profile of a man by Sir Joshua Reynolds; Pylaides and Orestes by West; and the Blind Fiddler by Wilkie. Sir George was one of Wilkie's earliest patrons and best friends. There are also two of his own landscapes in the National Gallery—a small piece on wood, and Jacques contemplation the Wounded Stag, from 'As you like it.' These two pictures were given by Lord Beaumont after the death of Sir George. He died in February, 1827, without issue. Lady Beaumont, who was the grand-daughter of Lord Chief Justice Will, survives Sir George little more than two years; she died in July, 1829. Sir George was one of the first men of fashion.

Burke, Dictionary of the Peerage, etc., Cunningham.

Books of the most eminent Painters, etc., and Life of Sir David Wilkie; Catalogue of the Pictures in the National Gallery.

**BECCAFUMI, DOMENICCO,** a very celebrated painter of Siena, of the sixteenth century. According to Vasari, he was born at Siena in 1484, and died there in 1549; others give the respective dates as 1470 and 1541. His real name was Meccherino; that of Beccafumi was derived from his patron, Lorenzo Beccafumi, who placed him as a boy with Capanna, an obscure painter, to learn painting. He occupied himself chiefly in copying, and he was especially attracted by some pictures in the Vatican, on which he worked with great accuracy, and which he never lost, notwithstanding a subsequent sojourn in Rome, and the opportunities he had of improving himself from the recent works of Michelangelo and Raphael in the Vatican. He was in Rome during the Pontificate of Julius II., but remained there only two years. He painted in distemper and in oil, better in the former style, and his small figures are superior to his larger ones. Latterly when the fame of Michelangelo in Tuscany attained its extreme height, Beccafumi seems to have felt for him a kind of envy or indignation, and accordingly forsook his original simplicity of design for a species of clumsy plumpness, and his heads became harsh and ugly. He was correct in perspective, was fond of reflections and foreshortenings, and excelled at all his figures in composition; in other respects he was surpassed by his great rival Razzi. His best works are in Siena; he executed some at Florence, at Pisa, and some at Genoa for

**BURNET** presented Mrs. Beale with a copy of his History of the Reformation; she appears to have been highly esteemed by the clergy; many distinguished members of that body sat to her. Mr. and Mrs. Beale attempted to have her every voluntary charge. Mrs. Beale's daughter, at the end of one of the pocket-books they gave two shillings in the pound to the poor. Her husband, Charles Beale, had an employment in the Board of Green Cloth; he was also a painter, and, according to his journal, a connoisseur of Greek and Roman pictures. Mary Beale, who died in London in 1697, aged 65, and was buried under the communion-table in St. James's Church. Her husband and two sons survived her. One son, Bartholomew, studied under Dr. Sydenham, and practised pharmacy; his brother, Charles Beale, who was born in 1660, was a painter, and died in London. Her pictures, says Walpole, have much nature, but are heavy in colour. Several of her portraits have been engraved by R. White, F. Vanderhane, and A. Blooteling. Archbishop Tillotson's has been engraved, and the latter engraved that of Archbishop Tenison. Walker painted Mrs. Beale's portrait; and several poems were addressed to her, under the name of Belesea, by Dr. Woodfall.

(Walpole, Anecdotes of Painting, etc.; Essay towards an English School.)

**BEAUMONT, SIR GEORGE HOWLAND,** was the seventh baronet of the ancient family of the Beaumonts of Stoughton Grange, Leicestershire. He was born in 1575, was a gifted man, a distinguished patron of the arts, a friend of artists, possessed himself considerable skill as a landscape painter, and is, hitherto, one of the most munificent donors to the British national collection of pictures. He was married in the establishment of the National Gallery; in furtherance of which he promised to contribute part of his own collection at Cocketon Hall: he accordingly presented to the National Gallery sixteen paintings, chiefly landscapes—a landscape and figures by N. Poussin; Hagar and the Angel, Nascius and Edojo, the Death of Procris, and a study of trees by Claude; a view of Venice by Canaletto; a large landscape and figures by Rubens; a landscape and figures by Both, called Morning; a landscape, called the Return of the Arms of the A. of Bourdon; the Villa of Mecenas, and the Niobe of Wilson; a portrait of a Jew, and a sketch of the Descent from the Cross, by Rembrandt; a profile of a man by Sir Joshua Reynolds; Pylaides and Orestes by West; and the Blind Fiddler by Wilkie. Sir George was one of Wilkie's earliest patrons and best friends. There are also two of his own landscapes in the National Gallery—a small piece on wood, and Jacques contemplation the Wounded Stag, from 'As you like it.' These two pictures were given by Lord Beaumont after the death of Sir George. He died in February, 1827, without issue. preliminary to the commencement of a much more magnificent collection of books, pictures, curiosities, rarities, bijouterie, and other products of art or ingenuity, and the erection of a new building on Fonthill, the most conspicuous feature of which was a tower of great height. Mr. Beckford sat again for Hindon in the short parliament of 1806, and also in that which met in 1807; and he continued to reside chiefly at Fonthill till 1822, when he sold his estate and house there, with all the extensive improvements which had been made in it ever since he had purchased it, for the sum of 350,000L. His outlay upon the property had been, according to his own account, about 279,000L, scattered over sixteen or eighteen years. The reason he assigned for the great expense of building was that it was the reduction of his income by a decree of the court of Chancery, which had deprived him of two of his Jamaica estates. 'You may imagine their importance,' he added, 'when I tell you that there were 1500 slaves upon them.' Soon after this he sold his tower, which had been very slightly constructed, and not long finished, fell to the ground. It was about 260 feet high. Mr. Beckford now retired to Bath, where he erected another lofty building on the eminence called Lansdowne, to the north of that city. Till now his literary reputation with the general public had rested on his early tale of 'Vathek'; but in 1834, after an interval of fifty years, he again appeared as an author by the publication of an account of his first continental tour (in 1780), in a series of letters. He had left no manuscript for his travels in Portugal, 2 vols. 8vo. Lond. He told the writer of the 'Recollections' that these 'Sketches' were drawn up from notes very insufficient in themselves,' but that his memory supplied what was wanting. He was told that they were written many years before their publication: indeed in his Preface he observes that the letters had 'remained dormant many years,' and that most of them 'were written in the bloom and heyday of youthful spirits and youthful confidences, at a period when the old order of things existed.' No. 'Perhaps,' he adds, 'as they happen to contain passages which persons of acknowledged taste have honoured with their notice, they may possibly be less unworthy of emerging from the hides of their original manuscripts. These, with the dispossession of them, will, perhaps, have been, to all intents and purposes, the same as the last. The essay and graphic power of these letters were instantly and keenly felt;' and their appearance from the press was followed the same year by the republication of the 'Memoirs of Extraordinary Painters,' and the next by another volume entitled 'Recollections of an Excursion to the Monasteries of Alcobaca and Batalha' (in Portugal), made in June, 1794. It is distinguished by the same qualities with the previous volumes on Italy. From this time Mr. Beckford continued to live in retirement on his estate, which he did not sate with. He left two daughters, the eldest of whom, Susan Euphemia, was married to the Marquis of Clydesdale in 1810, and is the present Duchess of Hamilton. Of the tale of 'Vathek,' which has been oftentimes reprinted, Byron, a good judge on such a subject, says: 'It would be a great pity, in the event of this şikay, contented, complete, beautiful, of the same, beauty, description, and power of imagination,' it far surpasses all other European imitations of the Eastern style.

REDSTEAD. Bedsteads for domestic use, of whatever form, are most commonly made of wood, and of somewhat massive construction; but the much smaller space occupied by light bedsteads of iron and brass, their consequent superiority in favouring that free ventilation which is so important to health, and the great advantages which they possess in not having to be bowed, have led to their very extensive introduction in late years in the dormitories of barracks, hospitals, and other public establishments; while the elegant lightness of some of them, and the combination which they exhibit of beauty and utility, have given them a place in the great public and private establishments where they are used. In many cases, for articles of household furniture. Another class of bedsteads is claimed for bedsteads which possess those ingenious contrivances which have been devised for the comfort of invalids, and to facilitate the necessary surgical operations upon patients with fractured limbs, or such as have been subjected to amputation. In these cases, the bedstead is constructed in such a way as to allow the bed to be raised or lowered at pleasure, or even to be entirely removed, when the injuries incidental to even the most careful removal of the body. By means of such inventions, several of which, having been and are in use, have been proved by experience to be efficient, have been rewarded by the Society for the Encouragement of Arts, Manufactures, and Commerce. And in some cases, as those of the bed-riden patient may be varied in every conceivable way with little or no effort on his part, and the offices of the attendant and the surgeon may be performed with the greatest possible facility. Even these however have failed in one important point; for however perfect their mechanical arrangements may be, they cannot prevent the distressing consequences which arise from the unequal pressure of a body reduced to a state of extreme deformity upon a bed which, however soft, cannot supply a uniform support to every portion of its surface. In many of the cases where the patient has been left on the bed, to destroy life, mortification and death have ensued from this unequal pressure, notwithstanding the utmost care and the use of air-cushions and down-pillows to mitigate the evil. A great step forward has been taken by Dr. Arnott in his 'Invention of the Hydrosomatic or Water Bed,' which consists of a trough lined with thin sheets of metal, and partially filled with water, upon which surface that floats a sheet of waterproof India-rubber cloth, of sufficient size to completely fit the trough when emptied and secured to its upper edge in such a way as to prevent the escape of the water by capillary action. Upon this sheet is laid an ordinary soft feather-bed or mattress, which, floating on the yielding surface of the water, affords a support to the patient comparable only to that afforded by the water of a bath. Every point of the uneven surface of the body having, as it were, its separate column of support, the pressure is so equally distributed as to afford the patient comfortable support and effectual relief. And this is the case for all the most prominent points. The depth to which the body will sink in such a bed may be regulated by the thickness and buoyancy of the mattress, and any unusual position of the body is prevented by the light and buoyant nature of the mattress. In the case of a patient unable to leave the bed daily, either to lay a waterproof cloth above the mattress to receive the moisture which would, without it, descend through the mattress, and become condensed on the floating sheet below it, would render the bed damp and unwholesome; to lay a blanket, which should be frequently changed, to collect the perspiration which descends from the bed; or to place a layer of small pieces of cork, the interstices of which may afford a degree of ventilation between the mattress and the floating sheet. The perfect adaptability of the surface of such a bed to whatever may be laid upon it, allows the dressing of wounds, the application of poultices, and the performance of other offices of the sick chamber, without disturbing the patient. A full account of this invention is given in the 'Penman Magazine (Old Series), from the fifth edition of Dr. Arnott's Elements of Physics.'

REDSTRAW, Sir William, R.A., one of the most successful of the recent English portrait-painters, was born at Burford in Oxfordshire, in December, 1753, and was originally articled to a conveyancer at Stowe. But having a strong desire for painting, he determined to pursue it as a profession, and he obtained admission into the Royal Academy in 1772. Though with many able rivals, some of whom were the most eminent painters of the English school, Mr. Beechey early established himself, and in 1782 he was elected Associate of the Royal Academy in 1793, and was appointed in the same year portrait painter to the queen, of whom he painted a whole-

In 1780 he executed his principal work, a large equestrian picture of George III., the Prince of Wales, and the Duke of York, attended by Generals Dundas, Sir W. Fawcett, and Goldsworthy, representing the Third and Tenth Dragoons; for which he was elected a Royal Academician and knighted by the king, being the second artist upon whom that honour was conferred: the first was Sir Joshua Reynolds. West however had declined the honour. This picture is now at Hampton Court.

From this time Sir William was much occupied, and he painted the majority of all the persons of distinction, rank, and fashion of his time, including several portraits of nearly all the members of the royal family. Among his portraits are those P. C. S., No. 20.

of Lord Nelson, Lord St. Vincent, Sir W. Hamilton, Lord Cornwallis, Mr. Addington, afterwards Lord Sidmouth, John Kemble, &c. His portraits generally gave satisfaction, especially in their attitudes and expression, which are the difficult departments of portraiture. His colouring was gay and light, and his earlier pictures were well modelled; but his latest works are negligently executed. There is a portrait of Nollekens by Sir William Beechey in the National Gallery. He died at Hampstead in the month of January, 1859, at the age of 86. He was twice married, and left a numerous family, Captain Beechey, R.N., who was one of Sir E. Parry's lieutenants in his second polar expedition, is the son of Sir William Beechey.

(Art-Union Journal, February, 1859.)

BEGARELLI, ANTONIO, a celebrated modeller of Modena, where he was born about 1498. Who his master was is not known, but he was probably Guido Mazzoni, or Gropelli, who was born at Modena in 1443. He was the friend of Correggio, and is said not only to have instructed that celebrated painter in modelling, but to have even modelled many figures for him to facilitate his labour in the painting of the cupola of Parma, of which the numerous and strong fore-shortenings rendered models necessary. There are few of the works of Begarelly left; the principal is the Descent from the Cross in the church of Santa Margherita, containing many figures in the round rather larger than life, and of which, sometimes one looks upon them, says Vasari, 'le masori d'Forlì divenisar marmo, guai ale statue antiche.'—'If this clay were to become marble, woe to the ancient statues: an extravagant compliment, which the figures do not warrant, in the opinion of Florio, and no doubt truly. There is a traditional story that the figure of this Descent was modelled by Correggio, but probably without foundation. He died in 1565.

BEHAMI, HANS SEBALD, a very celebrated German painter and engraver of the sixteenth century, whose name has been corrupted into all shapes by many foreign and some German writers. He was born at Nuremberg in 1532; was one of the best of Albert Dürer's scholars, and was a man of great ability; but his proficiency was, according to tradition, equal to his ability. He was forced, through his bad character, to leave Nuremberg, and he settled in Frankfort, but not to reform, for he here set up a wine-shop and brothel, and is reported to have been drowned by the authorities about 1550, on account of his extreme depravity. This is the account of Hugen, who says that it was the practice to condemn various kinds of vice, and among them those, to whom he refers to Lersner's 'Chronik.' Doppeimay says he went to Frankfort in 1540, and died there in 1560. The particular nature of Beham's depravity is not mentioned further than that he published obscene prints at Nuremberg, and kept a whoredom in Frankfort. He, however, had no very industrious from the number of his works; and his depravity must have been such as were not inconsistent with industry in his art. As a painter he is scarcely known. His name is written Beham and Beham by good authorities, and some maintain that his name was Sebald only; but most of his prints, or those attributed to him, are marked with a monogram of H. F. and H. B. in upright capitals intermingled.

His prints consist of woodcuts, and of etchings and engravings on copper. Those marked with the P. were, according to Sandrart, his earlier works; and those with the B. from about the time that he went to Frankfort. His first instructor was his cousin Bartholomew Beham, likewise a pupil of Albert Dürer, and also of Marcantonio in Italy. Heineken enumerates 392 prints by Beham, including 56 woodcuts, and 21 done after his designs by other engravers. Bartsch describes even 450, of which 171 are woodcuts. He is reckoned among the best of the Nuremberg school of woodcutters, and many admire their prints. His prints are much in the style of those of Aldegrever; occasionally correct in drawing, but generally, especially in the draperies, in the Gothic taste. His engravings were derived to his use of many of his master's designs. His cousin, Bartholomäus Beham, was an excellent painter for his period. He was a pupil of Albert Dürer, and was sent by the duke of Bavaria to study in Italy, where he died, says Sandrart, in the prime of life, and, according to Doppeimay, in 1540, which is also the last date upon his works: he was born about 1496.

Barthel Beham was extremely laborious and careful in his paintings; but if it be true that he studied in Rome in the later years of Raphael's life, his taste at design is no less exquisite, which is the chief requisite of a master. His reincarnation of a woman by touching her with the cross is one of the masterpieces of the old German school. The set takes place in the presence of the empress Helenas and a crowd of spectators; and the picture has the following inscription: 'Oliverio Del Corno...Pintor (Vedriani, his great works of art, was, according to Sandrart, assisted Marcantonio in executing the prints of Raphael. There is a print of Charles V. by Barthel Beham, which Vasari seems to have attributed to Marcantonio. His prints are better drawn than Hans Sebald's, but they are not nearly so numerous: they probably do not exceed 70. Many of them were sold for the benefit of the son of the painter. Samuel Terlinden says that some of the prints which bear the name of Antonio were executed entirely by Beham.

BELEMNITE. The group of Belemmites was first distinguished by Mr. Hutton as a separate order, in his 'Exposition of the Kinds of the Animal Kingdom,' 1795. It is characterized by a ventral and anterior face by a long narrow fissure, is the named generally by D'Oibriryg. To this group belong B. macrourus, B. grandifrons, B. mannamarticus, &c., in Europe and B. Americanus in the United States, if this last be really distinct from the others. It is said by Mr. Gmelin to be divided into two genera, B. mesoleucus, B. planiscopus of Sclater, &c., in the United States, if this last be really distinct from the others. It is said by Mr. Gmelin to be divided into two genera, B. mesoleucus, B. planiscopus of Sclater, &c., in Europe.

BELEMNITES. To the history of this singular group of cephalopodous fossils the progress of careful research has lately added very important facts. In addition to the circumstances attending the discovery of some traces of the general form of the animal at Selenis, and of the ink-bag and horny lamiae at Lyme and Whitby, we have record of almost complete restoration of the Belemnite animal from fragments laid upon in the cutting of the Great Western railway, near Lane in Oxfordshire, and excavated according to Mr. Pratt and the Marquis of Northampton admirable specimens of the phragmaceous and laminar plates, outlines of some of the soft parts of the body and arm, and the form and arrangement of the hooked appendages of the arm. Indeed one of Mr. Pratt's specimens reveals the place and size of the eyes, the funnel of breathing-tube, the tendinous parts of the mantle, and the lateral fins, the inhaler, and ink-duct. (Owen, H. V. Lectures, 1847.)

For this purpose the plates and fragments of the animals were submitted, has found a strong resemblance between the fossil animal and the group of recent Sepidid animals called Oxycheuthoids, on whose arms are not the usual orange patches, but slender horny hooks. The animal, eighteen inches long, lived in the Cretaceous, and the plates and hooks almost all the length, alternating in a double row. The fins appear round, and a little behind the middle of the body, as in Sepia; the caudal extremity pointed, enclosing the fibrous guard, the anterior extremity of the laminar plate, which is the ink-bag placed, nearly transverse, and not arched so as from analogy with the sepioide might have been expected. The_Cephalopod animal—a dichotomate eight-armed mammal, in some instances, to judge from sections of the fibrous extremity of the arm (arms included) four or more feet in length, and its figure appears favorable for swift motion. In the base deposits shales of some of the species appear to have persisted together, and we have found about the comes many indications of the presence of animal substances.

The geological distribution of the Belemmites has been largely examined. In 1856 Professor Phillips presented to the British Association at Dublin a full account of the strata in which they are met with, and of the various names and characters to the principal groups which occur in the cretaceous, upper oolite, lower oolite, and liasias strata. M. d'Orbigny has lately published results perfectly accurate. The species derived to this group, which are next occurring in France. It thus appears that in the first place Belemmites are confined as a group to the mosasian strata: that many species allied to the B. compressus of Volz, B. papillosus of Blainville, and B. paullus of Schlemmer, belong to the line; that others allied to E. filifera of Miller, B. quinqueloculatus of Blainville, B. Aanela of Volz, B. ooliticus, subproter, Anno cellus. There is in the museum a collection of a picture in a similar style of Marcus Curtius leaping into the Gulf. Barthel was also an engraver, and, according to Sandrart, assisted Marcantonio in the prints of Raphael. There is a print of Charles V. by Barthel Beham, which Vasari seems to have attributed to Marcantonio. His prints are better drawn than Hans Sebald's, but they are as nearly so numerous: they probably do not exceed 70. Many of them were sold for the benefit of the son of the painter. Samuel Terlinden says that some of the prints which bear the name of Antonio were executed entirely by Beham.
to a lower cuticle series; that others allied to B. subcutis of Miller, B. altidorsensis of Schlotheim, abound in the period of the Oxford clay; while B. macronus, B. quadratus, B. Listeri, B. attenuatus, and others now ranked as Blemnites by D'Orbigny, characterise the cretaceous strata. The investigations entered into on the subject have not been wholly fruitless; but the reader may refer with advantage to the Treatises of Blainville and Volzi, to Buckland's Bridgewater Treatise, D'Orbigny's Palaeontologie Francaise, and to Darwin's Origin of Species. Several points occur in Mantell's 'Medals of Creation,' vol. ii.

BELL, DR. ANDREW. (Schools, Primary, P. C.)

BELL, GEORGE JOSEPH, a writer on law and jurisprudence, was born at Fountainbridge near Edinburgh, on the 30th of July, 1775, the second son of Patrick Bell, and became a member of the faculty of Advocates in 1791. In 1804 he published, in two volumes 8vo, 'A Treatise on the Laws of Bankruptcy in Scotland.' In 1810 he published an enlarged edition of the same work in 4to, with the title 'Commentaries on the Laws of Scotland, and on the Principles of Mercantile Jurisprudence considered in relation to Bankruptcy, Competitions of Creditors, and Imprisonment for Debt.' A fifth edition of this work was published in 1826, together with seven volumes, with the title 'Commentaries on the Laws of Scotland, and on the Principles of Mercantile Jurisprudence.' 'Bell's Commentaries' is perhaps, next to Erskine's 'Institute,' the best known and most quoted treatises in the law. At the same time the late alterations in the bankruptcy law there [Bankruptcy, P. C. S.], it was the leading authority in that department of the law, and it continues to afford light on so much of the practical side of this act as has not been superseded; while in the other departments, that if it be not pre-eminently the best, is at least incomparably the best. A commentary on mercantile law necessarily involved not only a statement of the results of decisions in Scotland, but also a view of those generic principles in which decisions have been made on like questions in commercial law in England and Scotland so different from each other. One of the useful results of Mr. Bell's labours has been an assimilation, without any violent distortion of principle, of the practices of the commercial law of Scotland to that which has long existed in England. Of the Commentaries, Sir Samuel Romilly said: 'I consider it as one of the best, if not the very best law-book that has been published in my memory.' On the 27th of May, 1819, after the publication of the third edition of his work, the legislature granted to him a pension of £1,400 a year. Mr. Bell wrote 'Principles of the Law of Scotland,' which has gone through several editions; 'Illustrations of the Principles of the Law of Scotland;' and several minor works. He was at the head of a commission of inquiry appointed in 1817 to inquire into the condition of the public service. He had active exertions, very important organic changes were made in the administration of civil justice in Scotland. In 1821 he was appointed Professor of Scots Law in the University of Edinburgh; and in 1831 a principal clerk of session. He had married, in 1806, Barbara, daughter of Charles Shaw, Esq., of Ayre. He died on the 23rd of September, 1848.

BELL, SIR CHARLES, was born at Edinburgh in 1774. He was the son of a clergyman of the Scottish Episcopal Church, and born in a small parsonage in the county of Perth. The three elder sons, Robert Bell, John Bell, and George Joseph Bell, all attained eminent positions in life; the first was a distinguished writer to the signet in Edinburgh; the second attained the highest rank in his day as a surgeon; and the third long occupied the chair of Scots Law in the Edinburgh University. The youngest brother, Charles, did not receive quite so much academical advantages of education as his brothers, in consequence of the death of his father when he was quite young; but he received a good education, well in after-life, 'My education was the example set me by my brothers,' and most gratefully he always acknowledged the lessons which his mother bestowed on him, her favourite child. At the High School of Edinburgh he was distinguished for the eye of his brother John, whose profession he had adopted, that he first gave evidence of his great talents. He became a first-rate anatomist, and lectured to some hundred pupils on that science while comparatively a boy. His internal consciousness of ability, however, and the ambition inseparable from it, led him to long for increased opportunities of exertion, and in the year 1804, at the age of thirty, he removed to London. Perhaps the bitter dimensions then raging in the Edinburgh Medical School, in which his brother John was deeply involved, had some effect in persuading him to this change.

At the outset, the prejudices against Scotsmen which Johnson, Churchill, Wilkes, and others had so illiberally fostered, seem to have stood in the way of Charles Bell in his early days. In 1811 he married Miss Shaw, a daughter of Sir Astley Cooper, Abernethy, and other great surgeons of the day. His work on the 'Anatomy Expression,' published in 1806, did much to give him a name in London; and most deservedly so, that treatise being acknowledged by the learned as the most comprehensive, the most scientific, and the most complete treatise ever published on the subject of the human face; and the signers of the human face; and the signers of the type of the human face. Nevertheless, though advancing by slow yet sure degrees as an operative practitioner, Bell was forced to begin lecturing in a very humble way, having yet obtained no aid from association nor any connection with the chief medical schools. In the same year (1807) in which he entered on this course, he published his first edition of his 'System of Operative Surgery,' a work which was rendered valuable by its practical character: no single operation was described theoretically, but all from full personal experience. At this period, in some beautiful letters to his brother George Joseph Bell, he describes the dawning upon his mind of those discoveries, which, in after years, were monuments in the judgment of posterity. But he also grieves most bitterly in this correspondence, over the neglect with which the public, generally, treated those early speculations.

We may once for all observe, regarding this series of fraternal letters, that if the elder Bell did not live to see the arts which they would form in themselves satisfactory testimony to his abilities. His frequent aspirations 'to be chief of his profession in character' indicate a man of no common stamp.

In 1811 he married Miss Shaw, and brought happiness to his heart, and several of whose relatives have become eminent in their various departments. John and Alexander Shaw (the latter only now living) obtained high reputation as surgeons and anatomists under the eye of their brother-in-law; Patrick, another of the family, is now a distinguished member of the Scottish bar. To Alexander Shaw we owe an able vindication of the just claims of Bell in the field of anatomical and physiological discovery. In the same year (1811) Bell became connected with the Hunterian School in Windmill Street; and in 1814 he was appointed surgeon to the Middlesex Hospital, an institution which he subsequently raised to the highest repute, and which he justly boasts, in 1836, of leaving 'with full powers, and 120,000l. in our pockets.' It was at the Middlesex Hospital that Bell's name became familiar to the public; and from his chair as operator, and from his style of lecturing—which, though not especially eloquent, was striking and suggestive—that his labours were crowned with success, both as regards the patients, the University, the public.
bers in which they were there distributed. Bell discovered and showed, that the nerves were naturally distinguished among themselves and clearly classified into two classes: (1st that the nerves of sensation, or the ear of the mind), and (2nd), and those of motion, were totally distinct in their character and origin. As regards the brain, he exemplified this fact strikingly by his experiments on the nerves of the senses, so specially called. A peculiar characteristic of the sinews or nerves of the muscles was reduced, as he demonstrated; a similar touch on the optic nerve gave no pain, but an impression of a flash of light. He found the difference between the peculiar and primary nerves of hearing and taste, as between the two organs of the eyes, and all the nerves of the other primary senses. He meditated on the sensations of the organs of the sense of touch, and to their muscles the power of motion or contraction. He, in fact, laid bare, for the first time, the great fact of a distinction existing in the nature and quality of the nervous energy, which before his discoveries had been all buddled together under one interpretation. As respects the body and spinal marrow, Bell discovered a division of the nerves, perfectly analogous to that detected by him in relation to the brain. The common nerves distributed over the animal trunk fulfil the two grand functions of giving sensation and motion. On cutting a spinal nerve, the older anatomists found both feeling and motion to be lost by the part which is thence supplied with nervous energy, and they concluded that the nerve carried both qualities. But Bell found no other superincumbent power, and he was rewarded by the discovery, that the two roots, by which the spinal nerves are connected with the vertebral medulla, derivate and bear from them different qualities—the anterior root conveying the tactile power, and the posterior root the motor power, that is the sensation power. Following up his inquiries, he discovered, likewise, the special nerve of respiration, and others with particular qualities, as to which before his time not even a conjecture had been made. It is impossible in a brief sketch to advert to all the great practical results consequent on these discoveries. The puzzling cases which often occurred, where sensation or motion were singly or severally lost, became clear to the eyes of competent practitioners; and operators received a warming and guidance which may have already saved the lives of many persons. Before quittting this subject—in which Bell may be named as a discoverer equal even with Harvey—we ought to point to one of his practical inferences from his own views, which establishes the existence of a sixth sense—that by which we attain our knowledge of distance, size, weight, form, texture, and resistance of objects. Two of his Essays, 'On the Nervous Circle,' and 'On the Eye,' have reference to this theory. The basis of it is, that the nerves of sensation play the part of reporters on the motor nerves, and indicate to the central seats of perception the condition of things in the influence of those nerves, thus forming the sixth or muscular sense. But I must seize the hints which the genius of Bell threw out to the profession about this time, in lectures and short essays. The operation for the cure of squinting, for example, by division of the contracted muscle of the orbit, had occurred to him. It was thought of Bell that he had the credit of the discovery, as letters before us fully prove. The existence of a vital attraction between the solids and fluids of the body was also an idea of Bell, now propounded by others as new. But his discoveries on the nerves certainly established his reputation. In 1824 the London College of Surgeons offered to him their senior chair of anatomy and surgery, which he accepted; and his lectures, which were received with great applause, formed the basis of a work on the 'Animal Mechanism,' published in 1839, 1839, by the Society for the Diffusion of Useful Knowledge. Two other works, which combine high scientific knowledge with such a popularisation of the subjects as fitted them to ordinary capacities, followed soon afterwards; the one is the 'Lectures on the Hand,' and the other, 'Illustrations of Paley's Natural Theology,' an accomplishment to Lord Brougham's work on that subject. In the mean time Bell was in the first rank of his profession, and had an ample attendance of pupils, not only of the juniors in practice. On the Continent he was even more highly estimated. Cuvier, Larrey, and other illustrious men of science, vied with one another in testifying their admiration of his talents and his labours. On the accession of Wellington to the throne, one of those selected for the high honours of knighthood with Herschel, Brewster, and others. When the London University (now University College) was established, he was offered the chair of Physiology.
also on the latter, before the outer coating, or shell, is laid on. When all is well dried, the 'shell' is lifted off from the 'model,' and the model is picked or cut off from the core piecemeal. If we suppose the core, the model, and the shell to be represented by a round cup placed over another, and the middle one to be removed, we shall see that a vacant space comes to be formed between the core and the shell; and when we further bear in mind that the exterior of the core gives the internal form to the bell, and the interior of that to the shell, then, the object of the whole arrangement will be clearly seen.

This internal cavity of the mould, between the core and the shell, is that into which the metal is to be poured. The cushion on which it is laid is filled up with loam or earth, to the level of the top of the mould; and in it a faint impression, on the lower part of the furnace is knocked or dug away, a narrow jet instantly pours out from the opening, and a stream of liquid fire (for so it seems to the eye) runs along the channel in the loam, and flows out through the two openings made in the shell, and greenish sparks. When the mould is full, the metal is allowed to remain till perfectly cool; the loam is then removed, the external 'shell' lifted or cut from the bell, the bell lifted off the core, and the core pulled down. If the bell be very large, it is even worked at the theatre St. George, and the bell, with three or four to ten or twelve hundredweights, six or eight may be cast in one pit at one time.

The tone of a bell depends conjunctly on the diameter and the thickness; a small bell or a thick bell giving, relatively, a more acute tone than one which is either larger or thinner. Hence the founder regulates the diameter and thickness according to the musical pitch of the tone which the bell is to yield; but as this cannot be rigidly attained by casting only, the bays (say a set to form chimbs) are smaller, and some part of the metal with a sharp-pointed hammer; reducing the diameter at the lower edge when the tone is too low, and reducing the thickness at the part where the hammer strikes when the tone is too acute.

While these sheets are passing through the press, the public journals announce the completion, by Messrs. Mears of Whitechapel, of a bell intended for the south tower of York Minster. It is larger than any other in the United Kingdom. The bell has been advertised as weighing between seven inches in height, with a diameter of eight feet four inches. It is seven tons heavier than the 'Great Tom' of Lincoln, and five tons heavier than the 'Old Tom' of Oxford. The metal took twelve days to cool. The clapper weighs between three and four hundredweight. The cost is about 2000l.

BELL-METAL. [Bell-Casting, P. C. S.]

BELLA, STEFANO DELLA, a celebrated Italian etcher on copper, born at Florence in 1610. He worked until his thirteenth year in the shop of Orizo Vanni, a goldsmith, when his own inclination, and some instruction he received in painting from his master's son, Gio. Battista Vanni, and in engraving from Crespi, induced him to give up the intention of following the business of a goldsmith, and to follow the arts. He accordingly applied himself to painting under Cesare Dandini, but he eventually adopted etching as his profession, being attracted by the prints of J. Callot, a distinguished pupil of Cantagallina. Some of Della Bella's works having attracted the notice of Lorenzo de' Medici, the brother of the grand-duke Cosimo II, that prince sent him to complete his studies in Rome, where he remained without scales, his drawings, his reputation, and views of the city. After his return from Rome, he went in the suite of the Tuscan ambassador to Paris, and remained there eleven years, and executed many of his best etchings, by which he obtained a great reputation. His subjects are battles, military, naval, historical, and imaginary. They are executed with freedom, with great delicacy, and are also well drawn, and he had a fertile and happy invention. Cardinal Massarin wished to retain him at Paris, and offered him the situation of drawing-master to Louis XIV., then a minor and a child. But he returned to Florence about 1647, and undertook that office to the prince Cosimo, afterwards grand-duke Cosimo III., a post which he held until his death in 1664. He was one of the best masters of the etchingneedle, and has been surpassed by few in the number of his works; their number is given differently by different writers, but probably they probably number about one hundred thousand. He died in so much, what he did he did well. Before his death he grew melancholy: his last works were six etchings of the Havoc of Death, which however he did not quite complete. There is a portrait by D. Belli in the Pitti palace of the grand-duke Cosimo III. His own portrait by Stoccalo has been engraved by Hollar.

One of his most valued etchings is a large view of PontNeuf, Paris, which, as originally issued in 1646, is very scarce.

Gandellini, Notizie Istoriche degli Intagliatori, &c.; Heineken, Dizionario dei Artiste, &c.; Huber, Manuel des Amateurs, &c.;

BELLEFROPHON, a genus of fossil shells, rich in species, which occur exclusively in the Palaesoclone formations, is in the Silurian strata, Devonian rocks, and mountain limestone. It has been generally referred to Cephalopoda, and considered analogous to Argonauta; but D'Orybony has given reasons for placing it with the Heteropod Molusca, and comparing it with Carinaria.

BELLIN, VINCENZO, a modern composer, of considerable celebrity, was born in 1806, at Catania, in Sicily.

In the harvest of the years 1837 and 1838 the Maestro di Capella rathér distinguished in his own country Bellini was educated in the Conservatorio at Naples, under Zingarelli, and in that city, before he had completed his twentieth year, he produced an opera, 'Bianca e Furnando,' at the theatre S. Filippo. Bellini, in the Scala at Milan ' Il Pirata,' and this was succeeded by ' La Straniera ' at the same, ' La Sonnambula ' at Naples, ' I Capuoliti ed i Montecchi ' at Venice, ' Norma ' at Milan, ' Puritani ' for the Teatro Argentina, and in 1838 undertook to compose a grand opera for the Accademia Royale de Musique, he retired to Pateau near Paris, under the hope of increasing his strength for the task; but pulmonary disease had made too great progress in his frame to be arrested, and he died the 2nd of April, 1839. Within a fortnight after he had quitted the French metropolis.

Bellini's moral character stood high, and his manners and compositions were in strict accordance,—agreeable, tender, and elegant. He rarely attempted the brist, and never aspired to the sublime, or even the lofty. A sweetness of melody, a fitness of harmony, and an adaptation of the sound to the sense, characterise all those of his works which have come under our notice. His constitutional tendencies seem to have been adverse to his in the Prussian portion of the Scala at Milan ' Il Pirata,' and this was succeeded by ' La Straniera ' at the same, ' La Sonnambula ' at Naples, ' I Capuoliti ed i Montecchi ' at Venice, ' Norma ' at Milan, ' Puritani ' for the Teatro Argentina, and in 1838 undertook to compose a grand opera for the Accademia Royale de Musique, he retired to Pateau near Paris, under the hope of increasing his strength for the task; but pulmonary disease had made too great progress in his frame to be arrested, and he died the 2nd of April, 1839. Within a fortnight after he had quitted the French metropolis.

wild state to varieties, sometimes all the flowers are found lieuate, more rarely they are all tubular. There are several varieties of the common daisy cultivated in gardens. There is a double variety called large-double, another double-quilled, and a single variety known by the name of hen and chickens. These varieties assume various colours from deep red to pink and white. They are easily cultivated, and form pretty plants for edges and borders, and continue in blossom a long time.

*B. syriacu* and *B. annua* are natives of Europe, but are not cultivated. The genus *Belium* closely resembles *Belis*, it differs however in possessing a pappus surrounding its fruits. The species are found in the south of Europe, and appear like *Belis vulgaris*.

(Bathe's, Manual: London, Cyclopedia of Plants.)

BELLOWS. [Blowing-Machines.]

BeloNostomus, a genus of fossil fishes established by the present writer; the species were found in 1778, 1779, 1780, 1781, 1782, 1783, and 1784, in the lagoon, colite, and chalk: the foreign in the oilite of Pappenheim.

BELOPTERA (Blainville), the shelly portion of a fossil cephalopod, intermediate between Belminites and Sepia. It occurs in the French tertiary strata, and includes B. Cuvieri, B. compressa, and B. belemniotides (Blainv.). Mr. Morris adds B. anomala and B. longirostrum, from the English tertiary.

BELOSEPIA (Volz). In this genus M. Volz ranks two species, the species B. Cuvieri and B. compressa) which form part of the Belopetora of Blainville.

BEOWULF. [Saxon Language and Literature, p. 490.]

BERBURRUP, or BURBERRA, is a commercial place in Africa, situated on the southern shores of the Gulf of Aden, and nearly opposite the British settlement of that name, in 10° 27' N. lat. and 45° 5' E. long. It is built at the head of a small inlet, which affords excellent shelter from all the prevailing winds throughout the year. The town consists of an assemblage of rude huts of various sizes, square, circular, and elongated, generally about six or seven feet in height, built with sticks covered with mats or skins. These huts are erected in November, or as soon as the first caravan arrives, and are dismantled at the end of the first month of April, when the greater part of the materials are taken away. Very few persons remain on this part of the coast during the eastern monsoon, owing to the soughing hot winds, which in June, July, and part of August, blow with great violence. The permanent inhabitants are a few Baram and some chiefs of the neighbouring tribes, who have houses of a larger size, which are divided into apartments.

The trading season commences about the end of October or the beginning of November, when the first caravan or ten from the interior arrive on the coast, and bring with them materials for constructing the huts, and immense droves of sheep, which are immediately embarked for the Mocha market before they have time to fall in sheep, as there is no pastureage for them about Berbera. After the beginning of the rains arrives very daily, and also vessels from all the neighbouring countries. The March califa however is the principal, and frequently consists of two thousand camels. These caravans bring ghee, coffee, sheep, myrrh, benoin, gum Arali, elephants' tusks, gold-dust, slaves, ostrich feathers, dry hides, and also an article called urra in Arabia, which is described as something like saffron in appearance, and is used in that country as an intostart for cooling the body; it is also mixed with flour and made up into cakes, in which slaves are said to be very palatable. Among the slaves are many Christians from the neighbourhood of Shoa in Abyssinia. The vessels which visit this place come from Busrosor, Muscat, Cutch, Bombay, Mangalore, Masul, Aden, Mozambique, Zanzibar, the import of blue and white cotton-cloth, Indian pieces-goods, European prints, silks, silk thread, shawls, red cotton-yarn called tannah, beads, sugar, rice, iron, copper, wire, zinc, dates, and a few smaller articles.

The coast opposite the back of Berbera is inhabited by the Somalis, and affords neither pasture nor cultivation to a distance of ten miles, the soil consisting of a coarse sand or gravel. Berbera is the harbour of Harrar, a large town in the interior; immediately upon which accounts is twenty days journey from Berbera, whilst otherwise the distance is from five to six days journey. It is also visited by six or seven tribes inhabiting these parts of Africa.

BERENICE, a celery-like coriandrum, of which B. chien known as an example, fossil in the oilite of Wilts.

BERGKALK, in Geology, the German term for our limestone.

BERGLER, JOSEPH, a distinguished recent historical painter, was born at Salzburg, in 1721, and was educated by his father, and gave such early evidence of talent, that he was sent, in 1776, to complete his studies in Italy, by the prince-bishop Cardinal Friman of Passau. In Italy he studied 6 and a few years with Martin Knoller at Milan: in Rome he was occupied with Mengo, Canova, and Giovanni Battista Cammacini, Tischen, and Volpato were his contemporary students there, where he remained altogether six years: he left the interval he went to Parma, and obtained the first ward of a great, and after this died from a violent fever, and was buried by Dalliah to the Philistines. He returned to Germany and settled in Passau in 1786, where he was appointed painter to the prince-bishop Cardinal Auperger. During this stay at Passau until 1800, he painted several excellent pictures for the churches of neighbouring towns, some of which have since been burnt. In 1800 Bergler was made director of the Academy of Prague, and his ability and activity enabled him to teach several very able scholars, who have all fallen under the spell of Bohemian art, and himself furnished altar-piece for many of the churches of Prague, and its vicinity: one of his principal works at this time was a large picture of Hermann and Thesmola, for Klopoost's 'Hermannsleid'. He died at Prague in 1848, aged 83. He commenced by executing some great facilities executed at least a century ago; and excellence consisted in his colouring, not so much in the compositions, as in a general effective composition of colour. He also etched many of his original designs with great ability.

BERGMEHL, [mountain-meal, Norwegian, pert, stild in mining, or a month of February in France, Fossor: P. C. S.]

BERNADOTTE, JOSEPH, KING OF SWEDEN, P. C. S.

BERNARD, FRANCOIS. This 'most curious traveler' as he is styled by our historian Gibbon, was born at Argos, then the capital of the province of Arcos. The year of his birth has not been ascertained, but it is very little appears to be known about him, until after his return from the East, and the publication of his travels. Voltaire supposes that he was born in the year 1625. But it seems quite probable that he was born a few years earlier, and that he cultivated his fancy as a profession, and after taking his degree of doctor at Montpellier, being, as he tells us himself in the first page of his book of travels, excited by the desire of seeing the world, he went over to Palestine and thence into Egypt. This was in the year 1643. He lived merely for the instruction of the French, and the rare good fortune of recovering from that fearful disease. Being in Egypt, he became very desirous of visiting and examining the Red Sea; and, while on the shores of the Red Sea, a favourable opportunity presented itself for going into the East Indies. In all the countries of the East, a medical practitioner may travel very well, and live as well as the best, without any money. Bernard's pupil seems always to have been very light. He lived twelve years in India, and he was said of them years he lived by Dr. Doli as physician to the great Mogul Emperor of Hindostan. Auriungebe. [Auriungebe, P. C. S.] The favourite and prime minister of that prince, the Emir or Onah Daulatmohed, who is described as the greatest and most efficient of all of the ingenious and no doubt very useful Frenchman, and took him along with him when he marched with an immense army to the conquest of Cashmer. Bernard has left us the best accounts of that war, of the march of this immense force, and with the people of that country while they were like an immense moving city. The guard of cavalry consisted of 35,000 men, and the guard of infantry of 10,000; we were computed that the camp contained 150,000 horses, men, and elephants; 60,000 camels, 60,000 camels, and between 300,000 and 400,000 persons. The correctness of Bernard's description of the country has been recognised and praised by every European traveller that has visited Cashmer since his time, Mr. George Forster, who was there in 1783 or 1784, says in a letter that 'his description of Cashmer is as lively as it is just,' that 'Messieurs Bernard enjoyed advantages which have
fallen to the lot of few Asiantic travellers, and, happily for the learned world, his talents amply improved them.'

Returning to France, his native country, Bernier began to publish. His first work, entitled 'History of the last Revolution of the States of the Great Mogul,' appeared in 1670, and was followed by 'Continuation of Memoirs of the Empire of the Great Mogul,' which was published at Paris in the year 1671 as 'Le Joli.'

In 1674-5 Bernier published an abridgment of the philosophy of Gassendi. In the second part of this abridgment he treats of the systems of Ptolemy, Copernicus, and Tycho Brahe, and gives a refutation of judiciously. (In the Lyen edition, which is the only one we have seen, the whole of this abridgment of Gassendi fills 8 vols. 12mo.)

This work was much read or very much praised at the time. He wrote a memoir on the quietism of the Jesuits. His 'Dictionnaire Historique' was published in 1690. Bernier's 'Doubts of Bernier on some of the principal chapters of his Abridgment of the Philosophy of Gassendi' (Parts, I vol. 12mo., 1683). The copy of this volume in the Library of the British Museum has at the bottom of the title-page, in Bernier's handwriting, 'à Monsieur Bayle.'

In 1695-6 Bernier made a second journey to Africa. He wrote a letter to the Berner, giving an account of the journey and the discoveries he made. Bernier's 'Dictionnaire Historique' was published in 1690. Bernier's 'Doubts of Bernier on some of the principal chapters of his Abridgment of the Philosophy of Gassendi' (Parts, I vol. 12mo., 1683). The copy of this volume in the Library of the British Museum has at the bottom of the title-page, in Bernier's handwriting, 'à Monsieur Bayle.'

Bayle had good-humouredly exposed a somewhat laughable mistake which Bernier had committed in translating from Gassendi's Latin; but he had also cited Bernier as a traveller with commendation. (Bayle, Dictionaries Historiques, &c.)

Bernier also wrote a treatise on Free-will, 'Traité du Libre et du Volontaire,' which was published at Amsterdam, in 1685. In his 'Études de Grammaire,' he declared that in the French language, the narrative is the more valuable and trustworthy. Major Rennell (Memoir for illustrating the Map of Hindostan) calls Bernier 'the most instructive of all East Indies travellers.'

He did not begin to write in a vain of September, 1685, and died in the month of September, 1686, in his 50th year, his death was caused by a stroke of cutting Malaya, made at a dinner party by the president D'Harlay, and that the old epicurean died of a broken heart. But these stories are very doubtful.

(Biographie Universelle; Bernier's own Works and Prefaces; J. Wille; and the other authors cited in the article.)

BERVIC, CHARLES CLEMENT BALVAY, the most distinguished engraver of France during the French Revolution, was born at Paris on the 1st of September, 1765, the son of J. G. Wille, and in 1784 was elected a member of the French academy of painting. A large full-length portrait of Louis XVI. which he engraved in 1780, from the picture by Callet, is one of the finest examples of his art. It is distinguished for excellent drawing, extreme softness of tone, and a true effect of colour, but is rather defective in force. It is entitled 'Louis XVI., Roi des François, Résident de la liberté, présenté au Roi et à l'Assemblée Nationale.' After the execution of the king, Bervic, wishing to escape suspicion, and at the same time preserve the plate, cut it in half, thus attaining both objects. The half plates were reunited after the restoration, and beautiful impressions were again taken from them, but the earlier impressions are much more valuable, and command very high prices. Muller of Stuttgart engraved the same picture.

Other masterpieces of Bervic's graver are the Rape of Delilah, and the Education of Achilles, after Guido and Beganul; La Mandragora, A. C. Lepicé; and the ancient group of the Lacocon, an admirable production.

Through a weakness he was some years before his death forced to give up engraving, and he employed himself to teaching engraving. He died in 1822. He was a member of the French Institute, and Chevalier of the Order of St. Michel, of the Legion of Honour, and of the Réunion. (Huber, Manuel des Amateurs, &c.; Bartisch, Peintre-Graveur; and the Amateurs d'Estampes; Gabet, Dictionnaire des Artistes, &c.)

BEVEL, or BEVIL is, according to Nicholson's 'Architectural Dictionary,' the name applied both to the oblique angle formed by two surfaces which meet at either less than a right angle, and to the instrument employed by carpenters and joiners for marking and transferring such angles. The common carpenter's bevel consists of a straight wooden stock, mortised at one end to receive a thin blade, which is usually formed of steel, and attached to the stock by a pin in such a way that it may be turned to any required angle, and secured by a tightening screw. This kind of bevel may be described as an adjustable T-rule, the transom of which may be placed at any required angle with the stock. The bevel is divided into two parts, a and b, pivoted together at c, and capable of being set to any angle by means of the brasses d, which is attached firmly to the ruler b, and passes through a mortise or slit e, in which it may be secured at any point by means of a binding screw.

The adaptation of the instrument to a curved surface is provided for by a flexible blade or riband of steel, secured to the ruler a at one end, but capable of being made to assume and retain any simple curve by means of the series of screws marked f, which pass through nuts or mortisae attached to the ruler a, and press against the steel riband by a kind of swivel joint which provides for the various angles of contact formed by the riband and the screws.

Where many articles have to be worked to the same angle, it is desirable to use a fixed bevel, made to the required angle, especially where one or both of the limbs are curved. When the interior angle of the bevel is that used by the workman, such an instrument is sometimes called a joint-hook: a familiar instance of its use in this way is in working the intradoses and radiating beds of arch-stones, which, for circular arches, will be alike in every part of the arch.

BEWICK, THOMAS, justly called the revivaler of wood-engraving, was born at Cherryburn, near Newcastle-upon-Tyne, in 1753. He acquired an ability to draw from his infancy, and was accordingly, at the usual age, apprenticed to Ralph Beilby, an engraver of Newcastle, who had some reputation in that city. Dr. (then Mr.) Hutton consulted Beilby upon the best method of engraving the diagrams to his treatise on Monerrash; the engraver strongly advised him to return from abroad, and said he should be cut in wood, for various reasons, and by Thomas Bewick. Accordingly, in 1770, the work appeared, with complete success; and was followed by several other mathematical works.

Bewick now attempted works of much higher pretensions. He designed a set of illustrations to Gay's Fables, and for one of the cuts, the 'Old Hound,' he obtained, in 1775, a premium for the best wood engraving offered by the Society of Arts. This work was published in 1779. In 1784 Mr. Saint published a set of 'Select Fables,' with cuts by Bewick. After these works he commenced, in partnership with his old master Mr. Beilby, to prepare a 'General History of Quadrupeds,' which was completed in 1790, went through several editions, and obtained Bewick a great reputation. The designs in this work are by Bewick and his brother John, who was his pupil; and they are all executed with great natural truth, and in a free correct manner. The cuts themselves are superior to anything that was ever done in the same style before, and are inferior only to the best cuts of the present day in clearness and delicacy of line, and the same advantage they still have the advantage. His History of Quadrupeds was followed, in 1795, by Goldsmith's 'Traveler' and 'Deserted Village,' Farnell's 'Hermit,' and Somerville's 'Chase.'

Bewick had a numerous school, and was latterly much occupied in teaching; and in his last works was greatly assisted by his son Robert and other able pupils, of whom Harvey and Chennel have since particularly distinguished themselves in the same line of art.

The most considerable of Bewick's latest works are 'The Fables of Aesop and others,' and his 'British Fishes.' His last work was a cut of an old horse, for the head of a paper against cruelty to animals. He died in 1828, aged 75; and is said to have left a very full autobiography of himself, which he had written in a very careful handwriting. It was considered a large cut of a bull of the ancient Caedonian breed, from Chillingham Park; a proof of this cut on vellum is worth about 20 guineas. Bewick's services are fully discussed in 'The History of Wood Engraving,' with illustrations by J. Jacob, and there is a short but considerable detail, in the 'Gentleman's Magazine' of 1820.

BIDENS, a genus of plants belonging to the natural order Composite, the sub-order Corymblifere, tribe Senecionideae, subtribe Helianthemine, division Bcaptivae. It is a familiar name applied to many species of handsome shrubs, with numerous discoidal heads sometimes radiant; the flowers of the ray neuter ligulate, of the disk, bexamphrodite, tubular; the receptacle flat; the involucres of two rows, the outer row spreading; the branches of the style surmountt by short discoidal heads, with peltate; the seeds; angular, or ovate; the petals terminating in 2-5 stili retroflexly hispid bristles. The genus has been named Bidens from the two bristles which most frequently surmount the teeth. A great number of species belonging to this genus have been described, but they are generally inconspicuous woods. They have been found in Europe and North and South America. Two are natives of Great Britain in marshy and watery places, B. bipartita and B. cernua. The latter is the Crepe-b Qioof Bidiens of Linnaeus. (Balclutha Syme; Lindley, External System.)

BIGBONE LICK, a place in Kentucky (U.S.), where great numbers of fossil mammals occur in a dark-coloured marly soil, covered by gravel and resting on blue clay. The bones of four species of mammoths have been found, very numerous. With them lie bones of Megalonyx Jeffersoni, Bos caminesis, Bos Pallitania, and Cervus Americanus. (Rogers, On American Geology; Brit. Assoc. Reports for 1843.)

BIGNIONIA, a genus of plants named by Tournefort after the Abbé Bignon, librarian to Louis XIV. It forms the type of the monopetalous order of Exogonia, Bignioneae. It has a campanulate 5-toothed rarely entire calyx; the corolla with a small tube, a campanulate throat, and a 5-lobed bilabiate limb; the stamens four, diadynamous, with the rudiments of a fifth; the anther discariate; stigma bilamellated; capsule siliqua-formed, 2-celled, with the dissimper parallel with the valves; the seeds in two rows, imbricate, transverse, with membraneous wings, and nearly one hundred. Many of the elegant plants have been described. They are usually climbing shrubs furnished with tendrils, with opposite, single, compound, ternate, pinnate, or digitate leaves. The flowers are mostly in terminal or axillary panicles. The calyx is trumpet-shaped, and are coloured variously white, yellow, orange, purple, violet, or rose.

All the species of this genus are splendid plants while in blossom, and deserve a place in every collection. Most of them flower in July and August. B. Millii, however, will bloom in November, but they only grow freely in stoves. A mixture of loam and peat is best adapted for their growth, and cuttings will strike readily under a hand-glass in best, either in mould or sand. The species which are most abundant in our gardens is the Bignonia radicosa. This ibis and some other species of Bignonia are now referred to the genera Spadithaea [Spatheodra (Spatheodra, P. C. S.)] and Tecoma. (Inca.)
P. C. S.] It is one of the few species capable of living in the open air against a wall in this country.

B. speciosissima, has square glabrous branches, glabrous conjunct leaflets, oblong lanceolate leaflets, simple axillary tendrils, and terminal exstipulate, racemose inflorescences with biclinous ligneous stems. It is a native of Guiana and the island of Arrowsmith. It is applied by the negroes to swellings of the feet, with which they are troubled.

The African species, B. fastigiata, has a terminal cluster of leaves; ovate-lanceolate, acuminate, glabrous leaflets; terminal, solitary, or twin flowers. This plant is a native of Jamaica, on the banks of rivers. It has white flowers, not unlike those of Datura stramonium, which come out before the leaves. The wood is of no value, but yielding itself properly, it might be a market under the name of ebony. It is said to be an antidote to the poison of manchineel.

B. Chica is a climbing plant, and has abruptly bipinnate leaves,uguiculate-ovate, acuminata, deeply cordate, glabrous leaflets; axillary pendulous panicules. It grows on the banks of the Orinoco. A red matter is extracted from its wood by the Indians, with which they paint their bodies. It is called Chica, and so it has been used in this country as a dye.

B. Allotropia has tetragonal branches, conjunct leaves, coriaceous elliptic leaflets, simple tendrilia, axillary 5-flowered pedunculata, 5-toothed calyx. It is a native of Guiana and the West Indies. It has large white flowers, and is distinguished from all other species of B. by its peculiar garlic colour; hence the French name liane à l'ail.

(Don, Gardener's Dictionary; De Candolle, Prodromus; Bentham's Outlines; Systema Plantarum.)

Bill del. The subject of the present volume, and so in his countrymen among the first—by some as the very first modern poet and writer of Holland, and also distinguished by his varied erudition, was born at Amsterdam in 1755. His studies at Leyden took a very extensive range, for besides philosophy and languages—most of the modern languages included—he applied himself to history, archaeology, jurisprudence, divinity, medicine; and geology; and appears, in short, to have left scarcely any branch of science untouched. If there seems to be some-what of a poem, I am of opinion that he will have suffered more in the latter part of his life than in the former. Genius usually breaks forth on inspiration of a different kind from that produced by the hope of obtaining premiums and prize-medals; and if Billerdiky's did not, it was perhaps in some degree a foreboding of his future career, which he was destined to follow. But his appearance, in the midst of the first volume of his poems, in the collection of the Leyden Society of Kunst door Arbeid, was an event of more importance than the poetical enthusiasm. It was the character of poet however that made his début in 1775, when his 'Invlok der Dichtkunst,' &c. ('The Influence of Poetry on States and Governments'), obtained the prize from the Leyden Society of Kunst door Arbeid.

The subject was hardly one which a youthful poet would have selected for himself, though one for which Billerdiky proved himself capable and more than ordinary. \textit{BILLARDIER,} a genus of plants named after Jean Jacques L. Lahillardière, a French botanist, who visited South America in 1815. New Zealand is the center of an expedition, and wrote the '\textit{Novae Hollandiae Plantarum Specimen,}' in two volumes, 4to. The genus belongs to the natural order Pittosporaceae, and has a calyx of 8 scuminate sepals, 6 petals with approximate claws, which are convoluted at the base, and a fruit or berry terminated by a style. The species are called Appleberries, and according Do George Don enumerates eight. They are climbing shrubs, natives of New Holland and Van Diemen's Land. The flowers are showy, and Prof. Binck has proved that \textit{B. longiflora} has climbing branches, the younger ones scarcely pubescent; the leaves lanceolate, entire; the pedicles 1-flowered, glabrous, one half shorter than the flower; the berries almost globose, to roose, glabrous. This plant is a fast grower to abundant flowerer; and when in fruit its fine blue berries make a handsome appearance.' (London.)

The other species are desirable shrubs for the conservatory. They thrive well when planted in an equal mixture of loam and peat. Cutting will readily root in sandy loam. They may also be raised from seed, which they produce in abundance.

\textbf{BILOCULINA.} \textbf{[FORAMINIFER, Fossil, P. C. S.]} 

BIRBI, a celebrated Venetian goldsmith, watchmaker, and painter, and one of the so-called little masters, was born about 1500, in Cologne; some authorities make him, incorrectly, a native of Nürnberg. He at all events lived some time in Nürnberg, and was probably the pupil of Albert Dürer. Sandrart says he studied with Marcantonio at Rome; all the accounts of him, however, are little better than conjectures. In 1546 Binck appears to have been living at Copenhagen as portrait painter to Christian VIII. of Denmark. Later he was living at Königsberg in the service of Duke Albert of Prussia, who sent him in 1549 on a commission to the Netherlands. In 1550 he was employed again by Christian VIII., to select a fit spot for the erection of a fortress in Holstein. He probably died at Königsberg, in the service of Albert of Prussia, about 1569.

Bartsch describes ninety-eight prints by Binck, including one woodcut. There are many other prints attributed to him, which are marked J. B., but these according to Bartsch belong to some other artist, who probably is the same who studied, according to Sandrart's account, at Rome. Binck's monogram is made of J. C. and B. interlining, the C signifying Colonians, 'of Cologne,' in one print the word Coloniales is written in full. Many of his prints have been considerably improved to profit by the deception, as is the case with the works of other celebrated masters. Binck's drawing is superior to that of the little masters generally, but his style is very similar to that of Barthel Beham.  

The initials B. answer to several of Binck's contemporaries, as Johann Bergmair, Joseph Brechter, Jacob Beutler, Johann Brosamer, and Julio Bonason. His monogram is also very like that of Hans Baldung, the difference being only that between a G. and a C, both generally indistinguishably expressed. Binck's marks according to the collection of Mariette, amount to 200; their subjects are various.  

\textbf{BINOMIAL EQUATION.} \textbf{[Equation, Binomial, P. C. S.]} 

BIRD, JOHN, a celebrated mathematical instrument maker in the last century, died March 31, 1776, aged sixty-seven years. He ' was brought up a cloth-weaver in the county of Durham. What first occasioned him to turn his thoughts to the art, in which he afterwards so much excelled, was his accidental observing, in a clockmaker's shop, the course and intrinsic divisions of the minutes and seconds on a clock dial-plate. Those offended him much. He divided another plate with great neatness and accuracy, and amused himself for some time with dividing and engraving dial-plates for the clockmakers. He observed all the figures upon his own instruments. He came to London in the year 1740, and certainly was in business for himself in the year 1745.' (Ludlam, in work presently cited, Preface.)

Bird began his career in London by dividing astronomical instruments both for Graham and Gardner, and afterwards carried on business in the Strand. His celebrated Greenwich quadrant, of eight feet radius, was mounted February 16, 1742, and was used by both Bradley and Maskelyne. Another instrument was erected at Oxford Observatory. His last work was the instrument with which D'Agllct and the two La Landes determined the obliterations of 50,000 stars. The Greenwich Quadrant was described by Lemonnier in his \textit{Description et Usage,} 
\textit{Paris, 1716.} In 1747 he received 600l. from the commissioners of longitude, on completion of a globe bearing the meridian of Greenwich. 'The method of determining the meridians,' &c., 1716; 'The method of constructing mural quadrants, exemplified by a description of the brass mural quadrant at the Royal Observatory at Greenwich,' &c., 1768.

In 1756, Mr. Ludlam, of St. John's, Cambridge, who was one of the persons appointed by the commissioners to inspect Bird's methods, published his 'Introduction and Notes on Bird's Method of Dividing, &c.' This treatise had been sent to Bird, and bore his certified attestation of its correctness. The method is a model of what is called the better. All I can say is, that he has nowhere misused my meaning; and if he can (by what he has written) can those understand my method of dividing who otherwise seek not, he will not lose his labor.—John Bird.

The explanation of the improvements on Graham's method of dividing, which has made the name of Bird celebrated throughout the astronomical world, has been given in \textit{Gra-}

\textit{duation, P. C.}

EDWARD, R.A., an excellent English figure painter, was born at Wolverhampton in 1772. As he evinced a strong inclination for drawing, his father, who was a clothier, apprenticed him to a tea-board manufacturer of Birmingham, with whom it was Bird's business to paint the boards. His labours in this way were highly profitable to his employer, who wished to retain Bird in his service after the expiry of the term of his indentures, but Bird preferred trying his fortunes in the world as an artist, and he accordingly set up as a drawing-master at Bristol. In 1807, when he was thirty-five years old, he exhibited some paintings at Bath, which were much admired, and sold for thirty guineas each. These were succeeded by a piece called Good News, which established his reputation. Other good works succeeded, among which the most celebrated was the representation of the Death of Eli, for 500 guineas, which was purchased by William IV., the second by the Marquis of Hastings, and the Royal Academy elected Bird an Academician. He now exhibited his masterpiece, the Field of Closutton, after the Battle, which was purchased by the Marquis of Stafford for 500 guineas. The most celebrated picture purchased his next picture, the Death of Eli, for 500 guineas, and he obtained it also a prize of 500 guineas awarded by the British Institution. The picture however was not at first a success: it was the joint work of three of the greatest of Bristol, who had commissioned Bird to paint it for 500 guineas, and the 500 for which the picture sold at the exhibition was divided among them. The profitable result of their speculation led them to give Bird a second commission, but his health was too exhausted for further labours.

In 1817 Bird was in London, and was introduced to the Princess Charlotte, at Greenwich House, by her friend Mr. Murphy, to whom the Princess said—'Mr. Bird is a very well-bred man—he has a very pretty way of talking.' He appointed him her painter, and he presented the princess with the Surrender of Calais, one of his favourite pictures. The visit to London produced a great change in his taste; he was no longer satisfied with the humble character of his usual subjects. The life of Sir Walter Scott, his friend, and his books, impressed him with the grandeur and domestic life, in pursuit of the imaginary greatness of religious and historical subjects—the Fortitude of Job, the Death of Sapphira, the Crucifixion, and the Burning of Balaam's Ass, were the fruits of these designs. In 1807, for France, which at the time was engaged to a Spanish show. This last undertaking was a great misfortune to Bird; he required the portraits of many persons of rank, natural
foreigh: the prevailing upon these persons to sit was a trouble and a difficulty which Bird had never contemplated. He completely failed in his attempt, and this disappointment proved to have done incalculable mischief, during his dying hour. He died in 1819, in his forty-eighth year, leaving his pages unfinished. His fate may serve as a warning to future artists who leave the paths of nature, simplicity, and truth, to picture the empty pages of state ceremonies.

The body, it is said, of the lyre by which he gained his popularity, he executed several which have not been mentioned—as the Blacksmith's Shop, the Country Auction, the Gipsy Boy, the Young Recruit, Meg Merrilies, the Game at Put, and some of his earlier works, as the Village Politicians, and the Pickleburgh.

'Towards the close of his life,' says Allan Cunningham, 'Bird's looks grew dark and melancholy; but this was less the fault of his mind than of his fortune; he felt that the world of fashion which he had worshipped was making its own return—neglecting while it praised, and spurning while it cursed.'

He was buried with all the honours of the city in the cloisters of Bristol Cathedral. Three hundred gentlemen followed his body to the grave; his son, a child of seven years of age, was the chief mourner. The expense of the funeral was borne by his widow, a singular instance of liberality on the part of the mourners, if, as reported, the funeral was made public by their express desire, and against the inclination of Mrs. Bird. Dr. Birkbeck voluntarily took upon herself the expense, and declined the offered assistance of the gentlemen who attended the funeral. (Cunningham, Lives of the most eminent British Painters, vol. i.)

BIRDE (or BREDE, or BIRD), WILLIAM, who is numbered among the most celebrated of our ecclesiastical composers, was born about the year 1840, and educated as one of the 'children' in the chapel of Edward VI., probably under the famous Thomas Tallis, whom he certainly was in all probability at an early period of his life. In 1860 he was chosen organist of Lincoln Cathedral, and in 1875, conjointly with Tallis, became organist to Queen Elizabeth, as well as gentleman of her chapel. It is said that the music of Bird was so much admired that he was released, both in his private and professional capacity. Peacham, in his 'Complete Gentleman,' speaks of him with great reverence, as does his pupil Morley, in his 'Introduction.' (Burney's Hist. iii. 83.) That he was great in his art, at a time however when that art exhibited more of study than genius, his compositions afford indubitable evidence. His complete Service, together with three Full Anthems, published in Boyce's 'Collection,' prove his musical learning, which is further evinced in his 'Caniones Sacrae,' or sacred songs, published in 1617, and in his 'Musicae Antiqua.' In 1623 he was admitted a freeman of the corporation of the 'Society of Musicians in Antiqua,' at London, and in 1625 a freeman of the corporation of 'Singers and Musicians of St. Paul's.'

Among these are 'The Carman's Whistle,' an air with variations by Bird, which, if actually and well executed by 'the virgin queen,' shows that her majesty was as completely mistress of her instrument as of her bishops. Indeed to perform this, even in the present day, puts the skill of a good player to a somewhat severe test. He also published other works, chief among which is his 'Musicae Antiqua,' in which he represents himself as not only a very sincere adherent to the Reformed religion—all of them displaying deep study, and a profound knowledge of musical counterpoint. But he is now generally known—for, in well known everywhere—by his canon 'Yea nobis, Domine,' a unique composition, which has rather gained than lost by the operation of time, formed as it is of materials so enduring, that in spite of the love of novelty, which in music is so influential, it has maintained its ground during nearly two centuries and a half. Some attempts have been for some time made to reduce it to a canonic form, and as a valuable leaf from Bird's laurels, he is still left in full possession of this, his richest, never-fading ornament.

BIRKBECK, GEORGE, M.D., was born January 10, 1778, the son of James Birkbeck, a banker, and later a merchant and banker. At the age of eight he was sent to school at the village of Newton, Lancashire, where he remained till fourteen, when he was placed with Mr. Dawson of Sedbergh, a man of considerable mathematical attainments, who had once been a shepherd; and he read the classics with a relative, Mr. Robert Foster. He displayed an early predilection for mechanism, and scientific subjects, which led him to select the medical profession as his pursuit. He commenced his medical studies in 1797, and at the age of eighteen repaired to Edinburgh, where he remained for more than ten years. In 1807 he became a pupil of Dr. Baillie in London; but at its close he again went to Edinburgh, and at the termination of his fourth session took his degree. His reputation in the university was established, and by the formation of a friendship with Brougham, Jeffrey, Sidney Smith, F. Horner and others, he afterwards attained eminence. While at Edinburgh he was put in nomination for the professorship of the Andersonian Institution at Glasgow, and his election was carried by a considerable majority. In 1808 he opened his first course of lectures at Glasgow on Natural and Experimental Philosophy. There was at that time no maker of philosophical instruments at Glasgow, and he was obliged to make his philosophical apparatus made by ordinary workmen. He had employed a timman to construct a model of centrifugal pump; and it was in the cellar which formed the workshop, while surrounded by the workmen who had made it, but were ignorant of its use, that he was first struck with the idea of giving a gratuitous course of lectures for the scientific instruction of the mechanics of Glasgow. In March, 1800, he communicated his wishes on this subject to the trustees of the Andersonian Institution, who regarded the proposal as visionary, and nothing was done during the session. At its opening in 1800, Dr. Birkbeck, taking advantage of the prospectus of his courses for the ensuing session, announced his intention of establishing a class 'solely for persons engaged in the practical exercise of the mechanical arts, men of the education he wished to impart,' in order to enable them of acquiring the smallest portion of scientific knowledge. In the style of these lectures he promised that he would study 'simplicity of expression and familiarity of illustration.' On his return to Glasgow a printed invitation was circulated in the different manufactories, while tickets for the admission of the most intelligent workmen in each manufactury into the mechanics class at the Andersonian Institution. The number who accepted this offer was not large, as the first lecture was attended by only seventy-five persons; but it gave so much satisfaction, and excited such general interest, that at the second lecture the number was increased to two hundred; at the third lecture above three hundred mechanics were present; and at the fourth above five hundred; and as the theatre was not sufficient to accommodate many more persons, it became necessary to limit the number of tickets. At the close of the course his mechanics presented him with a silver cup. Dr. Birkbeck continued his lectures to them for the two succeeding sessions; in 1804 he relinquished the professorship, and was succeeded by Dr. Ure.

In May, 1806, Dr. Birkbeck married a lady named Lloyd, the daughter of Samuel Lloyd, Esq., of The Farm, near Birkbeck, in Lancashire, who taught him the art of medicine and good practice as a physician. In March, 1807, his wife died, and he did not marry again until 1817, when he was united to the youngest daughter of Henry Gardner, Esq., of Liverpool.

While in active practice in London as a physician, Dr. Birkbeck had few opportunities of following up the labours which he had commenced at Glasgow for the advancement of scientific knowledge amongst artisans; but it was a subject which he had always at heart. In 1820, he executed for the London Institution a gratifying course of seventeen lectures at the London Institution. In February, 1823, the mechanics of Glasgow who attended the lectures at the Andersonian Institution, as a mark of respect for his character, and in gratitude to him as the 'liberal-minded projector and founder' of the mechanics' class, asked his consent to allow his portrait to be taken. In July of the same year they resolved to establish a school for their own instruction, to be called the Glasgow Mechanics Institution. By circumstances now tendered a general development of Dr. Birkbeck's speculations. In 1821 a School of Science had been established at Edinburgh, through the exclusive principally of Mr. Leonard Horner. In the 'Mechanics Magazine' for October 11, 1823, a paper appeared, entitled 'Proposal for the Establishment of a School for the Advancement of Mechanics,' and Birkbeck was at this time engaged in preparing an Essay on the Scientific Education of the Working Classes, and he wrote to the 'Mechanics Magazine' (of October 18th), offering information and every assistance in his power in the formation of the projected institution. He was soon active in the pursuit of
this object, and on the 11th of November, 1823, presided at a public meeting at the Crown and Anchor, which was attended, amongst others, by Dr. Lushington, Jeremy Bentham, David Vivian, Lord Brougham, who had attended the preliminary meetings, was absent from other engagements.

The question of enabling persons engaged in the mechanical arts to acquire scientific knowledge was now fully brought before the public in London; and after another meeting, on the 2nd of December, the first officers of the "London Mechanics' Institution" were appointed on the 15th of December.

Dr. Birkbeck was elected president, which office he filled till his death; and his son has since been annually elected. At the opening meeting, Dr. Birkbeck generously lent the sum of 3700L., for the purpose of building a lecture-room, &c. On the 20th of February, 1824, he delivered an inaugural address on the opening of the institution, which was followed by a lecture by Professor Millington.

Dr. Birkbeck's professional and scientific pursuits, and his services in various ways, in connection with objects of public utility, were continued to the last. He died December 1, 1825, at his residence in Finsbury Square, London, of a severe internal disease which occasioned great suffering. He left a son by his first wife, and two sons and two daughters by his second wife, who survived him. His funeral was attended by a large procession of the working classes, the members of the London Mechanics Institute and the committee of the Polish refugees and a number of Poles; and among the private carriages was that of the Turkish ambassador. Altogether about a thousand persons were present, and a notice of it appears in "Mr. Birkbeck's "Mechanics' Magazine," February, 1842, has the following remarks on his character and personal appearance.—"He was mild and equable in his temper and disposition, benevolent in spirit, and possessing great suavity of manners. He spoke with singular neatness and fluency; and his ideas were as clear as his language. Whenever he appeared among the mechanics he was welcomed as a father and a friend; he was highly appreciated by a very large circle of private friends, and was held in great esteem by the most eminent public men of the day. As he was one of the most eminent physicians of the metropolis, he belonged to the Whig school. He possessed a beneficial, benevolent countenance, a venerable and unprejudiced aspect."

(Mechanics' Magazine, vol. i., 1823; London Mechanics' Register, vol. i., 1825.)

In April, 1842, a meeting of the friends and admirers of Dr. Birkbeck was held at the Freemasons' Tavern, London, for the purpose of adopting some plan of testifying the public approbation which is due to him for his valuable services to his country. Dr. Brougham took the chair; the Bishop of Ripon, Lord John Russell, and many other eminent friends of the diffusion of mechanical knowledge were present, and a resolution was passed in favour of the proposed action. In Uniting Birkbeck professorship of machinery and manufactures, including the application of chemistry and other branches of natural philosophy to the arts; and that it should be incumbent on the professor to lecture in the country in vacation. This professorship has not yet been established.

BIRKENHEAD, a town on the Cheshire side of the river Mersey, which is rapidly rising into importance. It is opposite Liverpool, and the distance from one bank of the river to the other is 1400 yards. Birkenhead owes its origin to the foundation of a Benedictine priory in the reign of Henry II. The prior enjoyed the right of ferry across the river. Birkenhead was extra-parochial and a chapelry in the parish of Bidston; but by a local act it is constituted a township under the government of commissioners. In 1843 an act was obtained for including the township of Chagport-on-Grange, and part of the township of Oxton, within the jurisdiction of the commissioners, which now extends over an area of about 1300 acres. In 1833 an act was passed for paving, lighting, watch- ing, and otherwise improving Birkenhead, for regulating its police, and for establishing a market; and in 1841 another act was obtained for supplying the town with water and for lighting it with gas. In 1842 the town commissioners were empowered to purchase the manorial rights, &c., pertaining to the ancient ferry at Woodside, which is the nearest ferry to Liverpool; and in 1844, under another act, they purchased Monk's Ferry. In 1844 they obtained an act of still wider extent, under which a large number of extensive accommodations for trade and shipping are now in progress. The magnitude of these works may be inferred from the following abstract, which is taken from the estimates:

New market, 20,000L.; tollhall, 10,000L.; park, 25,000L.; docks in Wallasey Pool, 400,000L.; dock warehouses (by subletting), 500,000L.; ironworks in Wallasey Pool, on which Birkenhead is situated, into docks, as entertained several years ago, and originated with the late Mr. Laird, but it was not until 1844 that an act, as already mentioned, was obtained for effecting this object. The first dock of the new line of docks was commenced in 1844, and the area of the principal or floating dock will be 15 acres, a space exceeding that of all the docks in Liverpool, and it will have 10 feet depth of water. It will be surrounded by walls 20 feet high with sliding gates for shipping and discharging cargoes. There will also be a tidal basin of about 40 acres, accessible at all times by the large steamers employed in the coasting trade, and by all vessels whose draught does not exceed 15 feet; a harbour of which area 10 acres; a free use of the river-craft. In February, 1845, the commissioners purchased the Herelesemine dock at Liverpool, in order to accommodate vessels which require to unload or take on their cargo at Liverpool, by which means they will be saved the necessity of paying full dock charges. Besides these advantages a port, Birkenhead possesses a communication by railway with the populous midland counties, by means of a railway which joins the Grand Junction Railway at Crowe, 5 miles from Birmingham. A line of railway from Manchester into Cheshire will also closely connect Birkenhead with that town.

In 1839 the commissioners purchased the town of Monk's Ferry, which is reached by means of a tunnel, of about 500 yards in length, which cost 20,000L., and was opened October 17, 1844; and the other terminus is intended to be at the docks, which will also be reached by a tunnel. By these means the London and Birmingham and Grand Junction Railways may possess a water-side terminus for the Irish traffic.

The commissioners for the improvement of Birkenhead are in possession of all the necessary powers by which they may enable them to carry into practice all those sanitary regulations which have hitherto been so much neglected in large towns. One of the bad acts provides for the appointment of a Board of Health. The width of courts is regulated, and the streets already in progress are wider than in the best parts of most towns. In the north-west part of the township, on rising ground, a park containing 226 acres has been laid out, which will be drained, planted, and ornamented with two lakes. The whole will be divided into pleasure grounds and open spaces or gardens for the public. The elevation and design for villas and terraces are in the park are to be subject to the approval of the commissioners. On the western side of the park there will be a number of perambulations, or walks across, London. Birkenhead consists of about 3000 houses, and has a population of about 120,000, and an area of 3 acres, four of which are enclosed and planted as a shrubbery. The houses are handsomely built, and the townhall forms the centre of the southern side of the park. A market-hall is erected, which will be 430 feet long by 40 feet broad, with six entrances; and it is intended that there shall be 42 shops and 50 stalls, which will be pleasantly supplied with water from the roof. It is expected that the sale of surplus land in the immediate vicinity of the market will defray the cost of its erection. Slaughter-houses are also to be built in a suitable situation. The commissioners are also empowered to erect public baths. The number of churches is at present two; St. Mary's, built in 1817, and one recently completed. The church-yard of St. Mary's is proposed to be the burial-ground of the ancient priory. Preparations are now (March, 1842) making for the erection of a third church with a parsonage-house. There are quarries of good building-stone in the township. There is a well-known Independent and one Wesleyan chapel. Birkenhead has several good hotels, a news-room, a savings-bank, and several other useful institutions. The communication with Liverpool is kept up by small steam-boats which ply from Monk's Ferry three times a week. In 1843 the number of passengers by the ferries exceeded two millions. It is intended that the boats shall soon commence running every quarter of an hour at one penny, and for carrying goods, 6d. per cwt. They ply both night and day. A number of the ferry are a source of revenue to the town commissioners. In November, 1844, the receipts were 1844,
which was 48.2% more than in the corresponding month of 1843. Another source of municipal income consists of ground-rents; and when the docks are opened, there will be a

Several points and stalls.

The population of the chapelry of Birkenhead was under 16,000 in 1821; in 1841, it exceeded 50,000 at the present time, and is.

BERKSHIRE.

The statistics of BERKSHIRE, P.C., having been greater with less completeness and accuracy than those of other large towns in England, the present opportunity is taken for supplying omissions, and also of noticing various other matters not necessarily included in the returns of the other boroughs.

The parliamentary borough of Berkshire consists of the parishes of Berkshire and Edgborough, and the two hamlets of Derrington and Bordenley and Duffield-cum-Necklins.

Rhode Island is composed of the town of Providence, the parishes of Glocester, Middletown, Newport, and Warwick, each of which returns one representative to the.

The following particulars, abstracted from the census returns of 1841, show the population, &c. of the Berkshire and also of the borough:

<table>

Of the 128,922 persons born in the county of Warwick and residing in the borough on the 6th of June, 1841, there were 61,315 males and 66,887 females; born in other English counties, 22,950 males and 24,438 females; born in Scotland, 463 males and 257 females; born in Ireland, 2277 males and 2065 females; foreigner or British subjects born in foreign parts, 378 males and 179 females; and the place of birth of 839 males and 831 females was not ascertained.

The number of births in 1842 was 6094, which was 156 more than those of the preceding year. The number of illegitimate births was 207, or 4.1% per cent. In the same year the number of marriages was 1018, and 924 were solemnized according to the rites of the Established Church; 750 took place at registrar's courts, and the remaining 129 at parochial courts.

The number of men married under age was 25, or only 2-4% per cent., and the number of women married under age was 99, or 6-9% per cent. for England the proportions are respectively 4-5 and 13-5 per cent. of persons married under age.

Out of 3578 deaths (1839 males and 1749 females) there were 914 of children under one year, and 1667 of children under the age of five. In the previous year above one-half the deaths of children under one year were to be charged to small pox, and one-fifth to scarlet fever. There are only three towns, Manchester, Leeds, and Liverpool, where the infant mortality is higher. The annual proportion of deaths to the population is 2-7% per cent., and in the whole of England 2-2% per cent. but the mortality is higher in Liverpool, Manchester, Sheffield, and Bristol, than at Birmingham.

The number of inquests held in the borough was 263 in 1844; and the average of the five years, from 1840 to 1844 inclusive, was 256. In 1844 the ratio of inquests to the total deaths was 8 to every 1000 deaths. The highest rate of mortality was 20.1 per 1000 at the age of 1620, and the lowest at the age of 40-60.

1. A coroner for the borough was first appointed in 1839. The cost of the coroner's court in 1844 was 926L.

The density of population is greater in Birmingham than in several of the largest towns in which the mortality is higher. In the parish of Birmingham there are 33,250 persons to a square mile; but in the metropolis of London, the population is 3500 people to a square mile. There are no cell-dwellings; but there are about 30,000 courts, containing 12,254 houses, which, at four persons to each house, would give a population of about 35,000. The sanitary condition of the city is good, and typhus is rare. There are no cell-dwellings; but there are about 30,000 courts, containing 12,254 houses, which, at four persons to each house, would give a population of about 35,000. In 1838 the average weekly wages of 791 persons engaged in about one hundred different branches of manufacture and handicraft in Birmingham were as follows:—

<table>
<thead>
<tr>
<th>Age</th>
<th>Males</th>
<th>Females</th>
</tr>
</thead>
<tbody>
<tr>
<td>14 to 18</td>
<td>4716d</td>
<td>19s. 6d.</td>
</tr>
<tr>
<td>14 to 50</td>
<td>24s. 6d.</td>
<td>19s. 6d.</td>
</tr>
<tr>
<td>Adults</td>
<td>24s. 6d.</td>
<td>8s. 6d.</td>
</tr>
</tbody>
</table>

Of the above 791 persons, 33 per cent. were workers in braze and copper; 11 per cent. in iron; 5 per cent. in guns and pistols; 4 per cent. in gold and silver; 14 per cent. were glass-cutters; and the remainder were employed in a variety of other occupations. The average wages of adults are not high, but the income of families is often considerable when the wages of women and persons under 20 are added to the earnings of the head of the family. The occupation returns show that out of a population of 182,000, the number engaged in some kind of occupation which was specified, was—males above 20, 43,688; males under 20, 8,083; females above 20, 12,335; females under 20, 5,945; and 1224 cases the branch of employment was not specified. The number of persons of independent means was 3908; number of alms-people, pensioners, paupers, and beggars, 1075; number of ‘other persons’ (in persons in bagnes, prisoners, &c.), 499; and the resin of the population consists of the males under 20; 1621, above 20; 56,789, females above 20, 36,074 females under 20.

Steam-power was first employed in manufactures at Birmingham in 1780. From 1780 to 1815 only 42 engines were set to work; from 1815 to 1830 there were 175; and from 1830 to 1838 there were 129; the number in January, 1839, the number of steam-engines at work was 240, of 346 horses power. The total quantity of coal consumed per day was estimated at 340 tons; and the number of persons employed in connection with steam-power was 896 and 1762 females.

In the metal trades of the town 2156 horses' steam was employed, and the following is given as an estimate of the amount of power consumed in different branches:—

<table>
<thead>
<tr>
<th>Trade</th>
<th>Power (horses)</th>
</tr>
</thead>
<tbody>
<tr>
<td>210 horses' power</td>
<td>Employed by iron-founders, engineers, and smiths; and steam first applied to the purposes in</td>
</tr>
<tr>
<td>650 in rolling metals</td>

</tr>
<tr>
<td>170 in drawing wire</td>
<td>and first applied</td>
</tr>
<tr>
<td>201 in iron forges</td>
<td>and wrought-iron mills; and first applied</td>
</tr>
<tr>
<td>78 in nail-cutting</td>
<td>and first applied</td>
</tr>
<tr>
<td>122 in wood-screw making</td>
<td>and first applied</td>
</tr>
</tbody>
</table>

The remainder of the steam-power was employed as follows:—grinding flour, 257 horses' power; glass-works, 95; wood-saving, 129; paper-making, 60; colours and chemical preparations, 128; steam-grinding, 38; pumping, 444; sundries, 107; and engines of 169 horses power were not at work.

An office for assaying and making silver was established at Birmingham in 1773; and in 1825 for gold. From 1773 to 1839 there had been an assayed and marked 4,014,907 ozs. of silver. The quantity in the following years was:

<table>
<thead>
<tr>
<th>Year</th>
<th>Quantity (ozs.)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1773-4</td>
<td>16,883</td>
</tr>
<tr>
<td>1800-1</td>

<tr>
<td>1820-1</td>
<td>55,399</td>
</tr>
<tr>
<td>1838-9</td>
<td>114,500</td>
</tr>
</tbody>
</table>

The duty on gold and silver marked and assayed declined in each successive year from 4877l. in 1839, to 3344l. in 1842; and this falling off marks a period of general depression through the country. The quantity of gold assayed in 1839 was 2125 ozs.

The increase of wealth is indicated to some extent by the number of carriages which paid duty at different periods. In 1816 there were 404; in 1820, 897; and in 1838, 917; and in 1839 the duty was less than one-half of the amount charged in 1816. In 1838 a very elaborate investigation was made, under the direction of the Birmingham Statistical Society, into the state of the population of Birmingham; and the following are the results of this inquiry:—

At the time the inquiry was made the population was estimated at 180,000, and the number of children in the borough at 45,000. Of the children 48.5 per cent. were receiving instruction in day and Sunday schools, and 51.5 per cent. were not receiving instruction in either. From similar inquiries it has been ascertained that the number of children between 1 and 15 years of age who were not receiving instruction in any school was 17.8 per cent. in the borough of Bury, Lancashire, in 1839; 30.7 per cent. in the London parish in 1834 and 1835; 34.7 per cent. at York in 1838; 52.7 per cent. at Liverpool in 1835 and 1836; and 65.9 per cent. in four parishes in the city of Westminster in 1837. The number of children attending schools was less in Birmingham than in any of the above-mentioned places, except in Liverpool and in the four Westminster parishes. So far as the ability to write may be taken as a proof of education, the borough of Birmingham is below Cumberland, Westmorland, Northumberland, the North and East Ridings of Yorkshire, Durham, and Derbyshire, for out of 1018 cartages in 1842 there were 283 men (27 per cent.) and 448 women (44 per cent.) who signed the register with their names. The proportion for England and Wales in the same year was respectively 47 and 47 per cent.

The want of public places of recreation and of innocent amusement is much felt at Birmingham. Many years ago, when the town was far less populous, the artisan had a small garden in the suburbs, which he cultivated in his leisure time; but ground for such a purpose now and by has been taken up for other uses. Consequently, at the close of 1844 it was resolved that there should be public performances on the fine grass at the townhall once a-week, with the especial object of furnishing an agreeable and wholesome enjoyment to the working classes; and the plan is said to have succeeded. Quarterly tickets are issued at a small charge, and each performance is attended by a thousand or thirteen hundred persons. A subscription, amounting at present (March, 1845) to nearly 6000l., has also been raised for erecting baths for the working
In 1843 the police reported that there were 314 houses in the borough to which prostitutes resorted, in addition to 187 in which the trade was carried on. In about 4000 aye streets, weekly ending February 17, 1846, the number charged with felony was 23; misdemeanour 24; drunkenness 26; vagrancy 2. On an average of ten years ending Lady-day, 1842, the annual sum expended for the relief of the poor was $12,936. In the Municipal Er of out-door paupers 629; out-door cases 3290, which, assuming each person to represent 24 persons, would make 8126, and the total of in and out door paupers would therefore average weekly $819: in 1836 the number was 11,893. To this number must be added 286 persons employed in stone-breaking, and who may be supposed to represent 902 persons, and there were besides 4531 vagrants relieved weekly. The rates for the relief of the poor are collected and expended under a Board of Guar- dians appointed by act of 1834, and for the conduct of which there is now governed by an act of 1 & 2 Wm. IV. The number of guardians is one hundred and eight, who are elected triennially, and the overseers and churchwardens for the time being form part of the board. The rules and orders of the Guardians are fixed by the act, and the revenues are derived from the rate, and from the sale of the goods of vagrants, and from the revenues of the testaments, and from the proceeds of the sale of the land in the hamlet of Duddleston-cum-Nechells are under separate commisioners, and on the same day a bill was also introduced for effecting improvements in the local administration, cleansing, paving, surfacing, and cleansing public offices in the borough.

**BIRTH (INFANTICIDE, P. C.)**

**BISHOP, BISHOPRIC.**

Since the articles under these heads (P. C.) were written (in 1835) there have been several important changes in relation to the dioceses and revenues of the Church of England. The Act of 1834 (5 & 6 Will. IV. c. 77) removed the inequality in the extent of dioceses which has been in part remedied, first by the creation of the new sees of Ripon and Manchester, by 6 & 7 Wm. IV. c. 77, and next by remodelling the old dioceses. The newly created see of Man- chester will not be filled up until a vacancy occurs in thesee of Bangor or St. Asaph; and whenever such vacancy occurs the above two Welsh bishoprics will be unitcd, so that no addition will be made to the episcopal bench by the erection of Manchester into a bishopric. The see of Ripon was ap- pointed to the new see of Ripon soon after the passing of 6 & 7 Wm. IV. c. 77; and as the same act made provision for the union of the sees of Gloucester and Bristol on a vacancy occurring in either of them, the number of bishoprics in Eng- land will be reduced, but there will be no longer exist as separate sees, as their union has taken place.

The bishop is styled Bishop of Gloucester and Bristol, and the congé d’ésir for his election will be addressed to the chapters of Gloucester and Bristol alternately. The diocese of Ripon is formed of detached parts of the dioceses of York and Chester. The diocese of Manchester will consist of the whole county of Lancaster, except the deanery of Furness and Cartmel. The act 6 & 7 Wm. IV. made provision for uniting the see of Sodor and Man to that of Carlisle in 1834, but the see of Carlisle c. 30, its existence as a separate bishopric was preserved. The act 6 & 7 Wm. IV. c. 77, not only remodelled dioceses, but provided for a more equal distribution of episcopal revenues, according to the following scale:

<table>
<thead>
<tr>
<th>Archbishops</th>
<th>£15,000</th>
</tr>
</thead>
<tbody>
<tr>
<td>Canterbury</td>
<td>£10,000</td>

</tbody>
</table>

The other bishoprics are augmented by fixed contributions out of the revenues of the richer sees, so as to increase their average annual incomes to not less than 4000l. nor more than 6000l. Thus under an Order in Council, dated 21st June, 1837, on the next vacation of the following sees, they will annually contribute to the Episcopal Fund as follows: See of Canterbury 7300l. a-year; York 1100l.; London 5000l.; Manchester 3600l.; Bath and Wells 1000l.; and Carlisle 2300l. a-year. The surplus revenues are paid into the hands of the Ecclesiastical Commissioners, and constitute what is called the Episcopal Fund; and every seven years, from Jan. 1, 1837, a new return is to be made by them of the revenues of all the bishoprics, and the scale of episcopal payments is to be revised, so as to preserve the scale fixed upon by the act. Provision was also made in this act for a more equal distribution of patronage among the several bishoprics, proportionate to the relative magnitude and importance of their respective dioceses.
B I S 200 B I S

Under the Act 3 & 4 Wm. IV. c. 37, and 4 & 5 Wm. IV. c. 90, which reduced prospecitively the number of archbishops in Ireland from four to two, and the number of bishoprics from eighteen to ten, the alterations which it was intended to effect have already by lapse of time been nearly completed. In the number of archbishops created in 1759, and when the articles Branor and Bishopric, P. C. were written, there were also the bishoprics of Quebec, Jamaica, Barbadoes, and Calcutta. To these have been recently added the bishoprics of Toronto, Newfoundland, British Guiana, Antigua, Madras, Bombay, Australia, Tasmania, New Zealand, Gibraltar, and New Brunswick. Some of these bishoprics have been created by letters patent, and their revenues and jurisdiction are regulated by acts of parliament; but others, as those of New Zealand, Tasmania, Antigua, Gibraltar, &c., are not of royal or parliamentary creation, but have been established by the archbishops and bishops, in concert with or by consent of the ministers of the crown. In 1841 a meeting was appointed by the bishops and bishoprics of England and Ireland at Lambeth Palace, when it was agreed to undertake the charge of funds then raising for the endowment of bishoprics in the colonies, and to become responsible for their application. In no case do they proceed without the concurrence of the British government. In 1841, in pursuance of this resolution, the bishopric of New Zealand was created; in 1842, the four bishoprics of Guiana, Antigua, Gibraltar, and Tasmania; in 1844, Newfoundland and New Brunswick, and in 1845 Ceylon.

As funds for endowments are collected, these bishoprics will be consecrated for the Cape of Good Hope, and next for Sierra Leone, South Australia, Western Australia, Port Phillip, and for Northern and Southern India. British colonies or dependencies which are not within any diocese are considered to be under the Bishop of the Diocese of the United Church.

There are thirty-two Roman Catholic archbishoprics, bishops, coadjutor bishops, and vicars-apostolic in the British colonies. At Sidney, Quebec, and in Bengal, the Roman Catholic prelates are of the rank of archbishops.

In 1840 a very important act (3 & 4 Vict. c. 86) was passed 'for better enforcing Church Discipline,' which repealed the old statute (1 Hen. VII. c. 4) under which bishops were enabled to proceed against their clergy, and subjects of the colony. This act has not provided in every case of any clerk in holy orders of the United Church of England and Ireland who may be charged with any offence against the laws ecclesiastical, or concerning whom there may be any complaint of having offended against the said laws, it shall be lawful for the bishop or the archbishop, of which offence is alleged or reported to have been committed, on the application of any party complaining thereof, or if he shall think fit, of his mere motion, to issue a commission under his hand or seal to five persons, of whom one shall be his visé-general, or an archdeacon or rural dean within the diocese, for the purpose of making inquiry as to the grounds of such charge or report: provided always that notice of the intention to issue such commission under the hand of the bishop or the archbishop must be given to the offended, together with the names, addition, and residence of the party upon whose application or motion such commission shall be issued to issue, shall be sent by the bishop to the party accused fourteen days at least before such commission shall issue.' The bishop may at once pronounce sentence, by consent of the clerk; and such sentence is good and effectual in law. If he refuse or neglect to appear and make answer to the articles alleged against him, or if there be any doubt of his truth thereof, 'the bishop shall proceed to hear the cause, with the assistance of three assessors, to be nominated by the bishop, one of whom shall be an advocate who shall have practised for at least five years in the bishopric of the province, or a sergeant-at-law, or a barrister of not less than seven years' standing, and another shall be the dean of his cathedral church, or of one of his archdeaconies, or his chancellor; and upon the hearing of such cause the bishop shall determine the same, and pronounce sentence thereupon according to the ecclesiastical law.' While the charge is under investigation the bishop may inhibit the party accused from performing any services of the church within his diocese until sentence has been passed; but if the person accused be the incumbent of a benefice, he may nominate any person or person or persons to perform such services during his inhibition, and such person or persons be licensed by the bishop if they are approved of by him.

Appeals under the act are to the archbishop, and they are to be determined by him, in the absence of any criticism or advice of the Judicial Committee of Privy Council, and at least one archbishop must be present.

In matters of dispute between a diocesan and his clergy an appeal lies to the archbishop of the province in all cases excepting curates' stipends (1 & 2 Vict. c. 106).

Rolle, an old authority, contended that the archbishop might appoint a coadjutor to one of his suffragans who is firm or incapable. This power is now established by 6 & 7 Vict. c. 62, entitled 'An act to provide for the performance of the episcopal functions in case of the incapacity of my bishop or archbishop.'

In 1841 a bishop of the United Church of England and Ireland was appointed for Jerusalem. The King of Prussia first suggested the appointment to Queen Victoria, and it was arranged that the representative should be chosen from the crowns of Prussia and England; but the Archbishop of Canterbury has a veto on the selection by Prussia. The Bishop of Jerusalem is a suffragan of the Archbishop of Canterbury; but he cannot exercise episcopal functions in the diocese of Jerusalem excepting in the presence of the archbishop.

The Protestant Church of Jerusalem will comprehend persons using different liturgies and subscribing different articles of faith, who will be on terms of equality as members. The bishop may ordain Prussian clergymen, and give them the Augsburg Confession and the Prussian Liturgy and Englishmen, on their subscribing to their articles and liturgy. He is the legal protector of all Protantists of every denomination against the Turkish government.

The Act 1 & 2 Vict. c. 85 passed 'to establish a separate and distinct Church within the limits of the Diocese of New York,' and York, and such bishops as they might select, to consecrate a foreign bishop. The instructions given by the King of Prussia to his envoy with respect to the establishment of the episcopate of Jerusalem, are copied in the 'Ecclesiastical Gazette,' March 11, 1845.

At the present time there are twenty-four bishops of the Protestant Episcopal Church of the United States of America. In this church the superior powers of church government are vested in a General Convention, which makes the constitution of the Church. The Convention consists of two houses. The bishops sit as a body in their own right and form a separate House. The lower House is composed of lay and clerical delegates. Each diocese is represented by forty laymen and four of the clergy, who belong to the House. The members of the Diocesan Conventions are elected by the respective congregations or vestries. The General Convention, amongst other things, has the power of revising old and making new canons. It hears and determines charges against bishops: receives and examinons testimonials from Diocesan Conventions recommending new bishops, and decides upon their appointment: without the certificate of the General Convention a bishop cannot be consecrated. At the General Convention held and assembled at Philadelphia in October, 1844, 'sentence of suspension' was passed on a bishop by the House of Bishops. They adjourned him to be 'suspended from all public exercise of the office and functions of the sacred ministry, and in particular from all exercise whatever of the office and work of a bishop of the church of God.' The title assumed by a bishop in the United States is 'Right Reverend.'

The Bishop of the Methodist Episcopal Church of the United States has no particular province or district. Their time is chiefly spent in attending the different annual conferences of the church.

The Roman Catholic hierarchy in the United States is composed of five archbishops, six bishops, and four vicars-apostolic. The first Roman Catholic bishop in the United States was consecrated in 1790. England and Wales are divided by the Roman Catholic Church into 'Dioceses,' over each of which a bishop has been placed, who is a bishop in suffrage. The London District a
superseded by a bishop who is styled the Bishop of Olena; the Eastern District by the Bishop of Arhipol; the Western District by the Bishop of Pella; the Central District by the Bishop of Cambysopolis; the Lancashire District by the Bishop of York; the Irish by the Bishop of Cashel; the Northern District by the Bishop of Abydos; and the Welsh District is under a vicar-apostolic, the Bishop of Apollonia. Scotland is divided in a similar manner. Each Bishop of Cashel was empanelled in the province.

The Roman Catholic hierarchy in Ireland consists of four archbishops and twenty-two bishops. In the Charitable Donations (Ireland) Act (7 & 8 Vict. c. 97) the Roman Catholic prelates are designated for the first time since the Reformation by their episcopal titles. The first line of the Act begins, "And, in the name of Our Lord Jesus Christ, whose authority and influence is world-wide, to the Bishop of Cashel, but gathered together in the name of Charles the tiger, under the sanction of those "and one He breathed when his name was written and engraved on the page of Eternity," when first brought in, as 'any person in the said church of Rome' of any higher rank or order, &c.; and, on the proposition of the government, this was altered to 'any archbishop or bishop, or other person in holy orders, of the Church of Rome.' In December, 1844, a royal commission was issued constituting the Board of Charitable Bequests in Ireland, and the two Roman Catholic archbishops and bishop who are appointed members of the Board are styled 'Most Reverend' and 'Right Reverend,' and are given precedence according to their episcopal rank.

It is stated in a recent authority, that the number of Roman Catholic archbishops in Europe is 108, and of bishops 489; and that of the two bishops in other parts of the world, making a total of 731 bishops. In France there are 14 archbishops and 86 bishops.

BISTORTA. [POLYGONUM BISTORTA, P. C.] BLACK ROUD, USHER OF THE, is an officer of the House of Commons, the Clerk of the Black Rod, and is appointed by letters-patent from the crown. His deputy is styled the Yeoman Usher. They are the official messengers of the Lords; and either the Gentleman or the Yeoman Usher summons the Commons to the House of Lords, when the royal assent is given to bills. 'He executes orders for the commitment of parties guilty of breaches of privilege and contempt, and assists at the introduction of peers and other ceremonies,' (May's Parliament, p. 156.) Only one, and the most ancient, council of Nova Scotia is styled Gentleman Usher of the Black Rod.

BLACKBERRY. [Rubus, P. C.] BLAKE, WILLIAM. This extraordinary artist was the son of a London hosier, and was born in London in 1757. At the age of fourteen, his father was induced by his son's passion for drawing to apprentice him to an engraver of the name of Baisre. He was a diligent and enthusiastic student; the day he devoted to the graver, and the night to poetry, for the art of poetry was the only amusement of his life, and utterly indifferent to the goods of this life: he used to say—"My business is not to gather gold, but to make glorious shapes, expressing god-like sentiments." When he was twenty-six years of age, he married Catherine Baisre, who survived him, and was most devoted and attentive wife, and fully appreciated the peculiarity of his mind. They lived at 29, Poland Street, and there Blake, with his wife always by his side, produced a series of designs and poems, which are quite unique in the peculiar spirit of their conception, but notwithstanding their peculiarity, are replete with beauties of the highest order. The spirit of universal benevolence and just appreciation of the greatness of life, animate and inanimate, breathed in his poems, and cannot easily be surpassed; but the mere serialization is often very inharmonious. When Blake was only thirty years of age, Flaxman and another gentleman published a collection of his poems, and presented the printed sheets to the poet, under the hope that he might derive some profit from it, a belief which he absurdly entertained of the works of art. Several of these poems are remarkable for their true paths.

The first of his own publications were the 'Songs of Innocence and of Experience,' showing the contrary states of the Human Soul,' which appeared with about sixty-five etched illustrations. Blake is very peculiar and original manner; the designs are drawn and the poems written upon the same copper, with a secret composition (discovered to him by the spirit of Inspiration) for the engraving. When the uncovered parts of the plate were eaten away by aquafortis, the rest remained as if in stereotype. His wife worked off the plates in the press, and Blake tinted the impressions, designs, and letter-press, with a variety of pleasing colours.

His next work was 'The Gates of Paradise,' in sixteen small designs, of a very mystical character. This was followed by a series, dated Lambeth, 1794, of twenty-seven designs, four inches by six, under the title 'Urizen,' in which he seems to have attempted to represent hell and its mysteries; this extraneous work was afterwards destroyed by Allan Cunningham, 'is a little fearful to look upon; a powerful, dark, terrible, though unde- fined and indescribable, impression is left on the mind, and it is no hospit to be gone.' After the completion of this work, Blake 'endeavoured to write a larger and a more curious, to illustrate Young's 'Night Thoughts,' which he filled with many marginal designs; so much to the satisfaction of Flaxman in many parts, that he introduced Blake to Hayley, the poet, who wished him to make some illustrations to the Life of Cowper, and persuaded him to remove in 1800, to Felpham in Sussex. Flaxman was a constant friend to Blake, and the latter in his correspondence with him usually addressed him 'Dear Sculptor of Eternity,' and in the first letter he wrote to him from Felpham he called him 'Sublime Archangel.'

At this time Blake's mind was confirmed in that extraordinary state which many suppose to have been a species of chronic insanity. He was so exclusively occupied with his own ideas, that he at last persuaded himself that his imaginings were spiritual realities. He thought that he was conversed with the spirits of the long departed—of Homer, Moses, Findar, Virgil, Dante, Milton, and many others: some of these spirits sat to him for their portraits. He remained at Felpham three years, and then returned to London. His first work after his return was his Jerusalem, comprising one hundred designs, of figures of men, spirits, gods, and angels; and for which, united, he charged twenty-five guineas. His next work were twelve designs to Blair's 'Grave;' for Cromek he was to have received twenty-one guineas; but Blake was not allowed to engrave them himself; they were intrusted to Schiavonetti. These were followed by his 'Canterbury Pilgrimage,' a picture in water-colours or dis-tinct paper, exhibited in his brother's house in Soho, with some of his paintings in the same manner, of which he printed a 'descriptive catalogue,' containing many critical heresies, some sense, and much that is wild and absurd. The following extract from p. 37, though extreme, is founded in truth:—'As there is a class of artists who have entirely与时 cosa. men, so there is a class of artists whose whole art and science is fabricated for the purpose of destroying art: who these men are is soon known: 'by their works ye shall know them.' All who endeavour to raise up a style against Raphael, Michael Angelo, and the antique; those who separate Painting from Drawing; who look if a picture is well drawn; and if it is, immediately cry out, that it cannot be well coloured—those are the men.' Charles Lamb speaks of the 'Canterbury Pilgrims' in a letter of his friend as a very god-like spirit, and power and spirit, but hard and dry, yet with grace. In the same letter he says, 'I have heard of his poems, but never seen them. There is one to a tiger, which I have heard recited, beginning—'

'Tigers, tiger, burning bright—
Through the deserts of the night—'

which is glorious. But alas! I have not the book, and the man is blown, whether I know not—to Hades or a madhouse—but I must look on him as one of the most extraordinary persons of the age.'

In the descriptive catalogue of his exhibition, he makes some excellent remarks upon the character of Chaucer's Prologues; and some excessively severe remarks upon the 'Canterbury Pilgrimage' of Stothard. He seems to have injured himself very much in the opinion of the world by the extremities he went to in this catalogue; he was comparatively neglected after its publication, and the demand for his works very much declined. He became extremely poor, but continued to produce new works, as Twenty-one Illustrations to the Book of Job, which are among his best productions; two works of prophecies, one on Americas, in eighteen plates, the other on Great Britain, in seven plates; and many small engravings of Dante, of which however he engraved only seven. His last performance was a likeness of his faithful wife, who, through his eccentricities reduced to the extreme of poverty, was never even inquired to complain. Blake himself never regretted his extravagance; he could not help being a Tristram Shandy, and he pitied his fortunate contemporaries for their inordinate love of gain. He died on the 12th of August, 1828.

Blake lays a great stress upon drawing in his criticisms, yet there are few of his works which are true in this respect the test of criticism—his figures are heavy and ill proportioned, his outline is sharp and cutting, and the anatom-
marks of his figures are exaggerated and coarse—his happiest efforts are in his conceptions, and his designs are often best with least taste. As to the peculiarities of his poetic fancies, there may be various opinions; his Songs of Innocence and of Experience are more poetical than his designs, the characteristic extravagancies of which are much more the symptoms of disorder in the imagination of the visionary than of any an utterly controlled and undisabled imagination, which is the secret of their supposed originality; and this want of mental discipline is the extent of Blake’s madness; his reason was unimpaired, but he devoted all the other faculties of his mind to the inventions of fancy he made many of, and wrote many poems which have not been published. He wrought much and slept little,” says his biographer, and has left

...
which tested the power of the method to the fullest extent was the one about to be noticed. It was in January, 1849, that Mr. Cubitt made the first of his attacks on the Seven Dials. For low hills was the area—The six or seven miles intervening between Folkestone and Dover exhibit a continued series of bold cliffs connected with the South-Eastern Railway; and it was as part of this course that the necessity occurred for a process of clifftopping to be adopted. The line from Folkestone, there is first a viaduct of great height and length; then the Martello tunnel, about a third of a mile in length; then the Warren cutting, a very deep excavation, twelve miles in length; then the cliff-cuttings, which are a mile long; next a sea-wall, built up against the scarped face of the cliffs for a distance of two miles; then the double tunnel through the Shakespere Cliff; and, lastly, a timber viaduct along the face of the cliffs to the Dover terminus. Now in drawing a straight line from the Abbot's Cliff tunnel to the Shakespere tunnel for the sea-wall, it was found that a bulky promontory, called the Round Down Cliff, stood directly in the way. It was first attempted to tunnel through this cliff, but the soil being unfavourable, the idea of removing the cliff at one blast by gunpowder occurred to Mr. Cubitt the engineer; and there have been few examples in which a first attempt, on a vast scale, has so fully succeeded.

The arrangements for the explosion were thus made:—A horizontal trench was made, with broaching and wire, extending for about one hundred yards parallel with the intended line of railway, in a direction nearly east and west. Cross-galleries were driven from the centre and extremes of this main gallery. At the end of each cross-gallery shaft, which was about twelve feet in diameter, were connected, by a horizontal passage eleven feet long, five feet high, and four and a half wide. In the eastern chamber were deposited about 6000 lbs. of gunpowder, in the western 6000 lbs., and in the central 7600 lbs., making in all, or more than eight tons. The gunpowder was packed in bags; these bags were placed in boxes; loose powder was sprinkled over the open mouths of the bags; and the bursting charges were placed in the centre of the main charges. The distance of the charges was the same as that previously used on the cliff. The depth of the cliff was about seventy feet. These being the underground arrangements, those for firing the charge were as follow:—On the surface of the ground, behind the cliff, was a wooden shed for containing three galvanic batteries; each battery consisting of eighteen of Professor Danieli's cylinders, and two common batteries of twenty plates each. The wires from these batteries communicated at the other end by means of a very fine wire of platinum, the red-heating of which by the passage of the electric current caused the wire, coated with wax, were extended on the grass to the top of the cliff, and then falling over the edge, were carried to the three excavated chambers, and placed in connexion with the charges. The wires from the passages and entrances to the powder-chambers were 'tamped,' or stopped up with dry mud, rammed down hard.

At two o'clock in the afternoon of the 26th of January, all the preparations being ready, three engineers worked the three batteries simultaneously; the three wires conducted the electric current to the three chambers, and the mighty explosion took place. Many had expected that noise, smoke, and fragments hurled to a vast distance, would have accompanied the explosion; but such did not occur. The rock seemed almost as if it had exchanged its solid for a fluid nature, for it glided downwards into the sea in one body. Sir John Herschel, in a communication to the 'Athenaeum' immediately afterwards, says, 'Of the noise accompanying the immediate explosion, I can only describe it as a low murmur, lasting hardly more than half a second, and so faint, that had a companion at my elbow been speaking in an ordinary tone of voice, I doubt not it would have passed unheeded. Nor was the fall of the cliff (accompanying the explosion) in no less than 400 cubic yards were, within an interval of time hardly exceeding ten seconds, distributed over the beach on an area of eighteen acres, covered to an average depth of fourteen feet, and in many parts from thirty to fifty) accompanied with any considerable noise or shock. In the absence of an attention, or that of several others similarly stationed, with whom I afterwards compared notes.'

The complete success of such an experiment (by which it is said that the stone has been reduced to powder in about a natural led to the adoption of similar means in other like cases. On March 2, in the same year, a second blast took place, a little beyond the Round Down Cliff, on a smaller scale than the former, as the mass requiring removal was not so bulky; there were 7000 lbs. of powder used, and 60,000 cubic yards of chalk dislodged. On April 18 a third blast took place, which consisted of 10,000 lbs. of powder. Later in the same year, in October, a fourth blast took place, in which the powder was distributed in twenty-eight distinct parts, deposited in as many separate excavations, and all were exploded simultaneously. The arrangement of the wires, dis-
nities is found for their growth. We find that as soon as a fruit becomes ripe its constituents commence union with the oxygen of the air, forming carbonic acid gas, and it is during this state of their elements that the fungus finds a soil ready for its development.

This idea of the taking of the rotting of fruits, their preservation must be conducted on the same principle, for what will exclude oxygen will exclude the spores of fungi. As a simple process it has been recommended to place at the bottom of a bottle a paste formed of lime sulphate of iron, and thus to introduce the fruit, which has been pulled a few days before ripening. The fruits should be kept from the bottom of the bottle and as much as possible from each other, and the bottle should be closed by a cork such as those made by peachmen, which may be kept from twenty days to a month; peaches and apricots for three months. Mr. Hassall recommends that fruits should be washed over with a composition consisting of water one pound, shell-lime and borax two ounces.

(Lindley, _Institutional Botany_; Hassall, _Transactions of Microscopical Society_, vol. I.)

**BLIGHIA**, a genus of plants named after Captain William Bligh, R.N. [Bligh, William, P.C.], belonging to the natural order Sapindaceae. It has a 5-parted calyx, five petals, a very short style, three stigmas, and a solitary seed with a very large aril. Only one species of this genus has been described, _B. sapida_, Alces-tree. It is a native of Guinea, from whence it has been introduced into the West Indies and South America. This tree attains a height of thirty or forty feet. It has pubescent leaves, with three or four pairs of oval-lanceolate veined leaflets. The fruit of this tree is a berry of a reddish or yellowish colour, about the size of a hen's egg, or even larger, the seed being a subacid flavour, and is eaten in Africa and the West Indies.

This tree does not produce flowers in this country. It may however be easily cultivated. It grows well in a mixture of loam and peat. Cuttings will strike in sand under a hurdles.

(London, _Encyclopedia of Plants._)

**BLITUM** (from _Blitrum_), a genus of plants belonging to the natural order Chenopodiaceae. It has no corolla, and a staminate flower with two stamens and a pistillate flower with two ovules in its herid calyx. Two species of this genus are known by the names of _Strawberry_ Blite—_B. capitatus_ and _B. nigra._ The former has its flowers in terminal spikes; the latter has its heads lateral and scattered. Some writers have made the _B. nigra_ only a variety of the first, but its auxillary flowers are constant. After flowering, the calyx of these two species swells out, and presents the size, appearance, and colour of the common wood-strawberry. It is succulent, Altarnated, and was formerly used in puddings. The taste is insipid. These plants are natives of Great Britain, but are common on waysides and in cultivated grounds in the south of Europe. The species of Chenopodium are cultivated in the botanic gardens, and many of them are closely related; Mr. Koch and Mr. Babington have both referred the European species of Chenopodiaceae to the genus _Blitum._ These are the _C. rubrum, C. Bonus Henricus_, and _C. pinnum_ of Babington's _Manual of British Botany_, all three of which are Linnaean species.

**BLIZARD, SIR WILLIAM,** was born at Barnes Elms, in the parish oflo, in 1743, when his father was an under-timer. His early education was neglected, but he was apprenticed to a surgeon and apothecary at Mortlake. During his apprenticeship he devoted himself to self-improvement, and paid much attention to botany. On leaving Mortlake, he became a student in London, and attended during that time hospital practice at the London Hospital, and the lectures of William and John Hunter and Mr. Pott. His assiduity recommended him to his teachers, and he was soon elected a student at St. George's Hospital. In 1780, he was elected surgeon to the London Hospital. About this time he connected himself with Dr. Macaulay as a teacher of anatomy, and they lectured together, first at a small place in Thames Street, afterwards in Mark Lane, and lastly at the London Hospital. Mr. Macaulay had such an institution for teaching medicine, it was the first that was established in London in connection with any of the large hospitals.

In 1767 Mr. Blizard was appointed Professor of Anatomy to the old Corporation of Surgeons, and in the year following he was unanimously re-elected. He was afterwards appointed an examiner. He was also elected a Fellow of the Royal Society in 1787. He took an active interest in procuring for the old Corporation of Surgeons a new charter, which was at last obtained, the new institution being called the Royal College of Surgeons. When this college was chartered in 1844, it is now called the Royal College of Surgeons of England. On granting of the first charter, Mr. Blizard was appointed, in conjunction with Sir Everard Home, a preacher of the order of the college, during his life, and delivered the Hilarian Oration three times. On the occasion of the great collection of John Hunter being presented to the college by the government, Mr. Blizard presented also his preserved specimens in human and animal pathology, amounting to about nine hundred preparations.

In 1796 he published a work entitled _Suggestions for the Improvement of Hospitals and other charitable institutions._ In this work pointed out the evils that existed at that time in the various institutions intended for the relief of disease. Such was the want of cleanliness and attention to ventilation in many of these places, that it was questionable whether they did not do more harm than good. This work of Mr. Blizard drew particular attention to these facts, and was followed by a beneficial improvement in many of the metropolitan hospitals; but such is the imperfect construction of the buildings, and want of attention on the part of the managers, that many of the charitable institutions, even to this day, are exposed to the charges brought against them in 1796.

In 1803 Mr. Blizard was appointed to present an address to the king, from the College of Surgeons, when he received the honour of knighthood. In 1819 he founded the Hunterian Society. This was the result of a distinct reference to medical men, and the discussion of medical topics at stated periods. He was the first president, and held the office three successive years. This society now possesses a good library, and its meetings are held on a Friday in the month of May in the Samaritan Society, which was instituted with the view of explaining the circumstances of cases in hospitals, that have a claim upon benevolence, of obtaining a fund from which relief can be given when it is required by them, and of properly executing and perpetuating the good design. This society has flourished, and now dispenses 500l. annually in the relief of objects of distress. Sir William took an active part in the formation of many of the metropolitan societies. He was one of the first founders, and for many years vice-president of the London Institution.

Besides being Surgeon to the London Hospital, and a member of the Royal College of Surgeons, Mr. Blizard held the offices of Consulting Surgeon to the Deaf and Dumb Asylum, the Marine Society, the Clergy Orphan Asylum, and the London Orphan Asylum. But with all his activity and industry, he did not escape the exception of an attack of fever, caught by working night and day, by which his health never failed him till the last. He belonged to a long-lived family; his father and mother died at the age of eighty-six, and his grandfather on his mother's side at ninety. In 1827 he was in his eigteenth year, but strong enough to make his first visit to Edinburgh. His eye-sight latterly failed him, and when this was discovered to be owing to cataract, he insisted, in spite of the entreaties of his friends, on having the operation of extraction performed. This was done by Mr. Lawrence in 1834, after which his sight was restored the use of his eyes. He was however now in his ninety-third year, and during the following year his strength and health visibly failed him, although he attended a meeting of the court of examiners at the London Hospital the last day before his death. He died on the 26th of August, 1835.

Sir William was tall in person, with features strongly marked. He was prone to jocularity, which exhibited itself in his conversation; and has obtained for him a place in the pages of _Joe Miller._ He was most punctuous in matters of etiquette, and retained the fashions of the last century to the day of his death. At one time it was customary for physicians and surgeons to attend at coffee-houses to be consulted. Sir William Simpson is said to have been in the metropolis who pursued this practice. He regularly frequented, for this purpose, Batson's coffee-house, Cornhill.

In early life, Sir William, in politics, was a great reformer. He regularly contributed to many of the periodicals of the day, under the signature of Curiosus. Some of these contribu-
plotted in the 'Middlesex Journal, or Chronicle of Liberty,' and in 'Freeholders' Magazine, or Monthly Chronicle of Liberty.' As he grew older, however, and his position in society improved, he became less democratic, was an admirer of Mr. Pitt, and a member of the Pitt Club. Subsequently, in his position of a member of the Council of the College of Surgeons, he was an opponent of all change in that body.

As a surgeon, Sir William Blizard never took the highest position in his day, but he was a good anatomist. His contributions to medical literature are few, and, considering the vast opportunities he must have had of witnessing all forms of disease in one of the largest hospitals in London, not so important or valuable as might have been anticipated. His principal papers are:—1. A new method of treating the Fimbria Labyrinthi, Phil. Trans., vol. Ixx. 2, 'Experiments and Observations on the external use of Tartar Emetic,' 1787. 3, 'Observations on the uses of Electricity in Deafness,' 1790. 4. Lectures on the Maritime School at Greenwich on the situation of the large blood-vessels of the extremities, explaining the use of the tourniquet,' 12mo., 1798. This was written with the view of affording sailors some knowledge of what could be done in cases of emergency from wounds of various kinds. 5, 'Observations on some epidemic effects,' 1792. 6, 'Hunterian Orations,' 1815, 1823, 1828. 7, Orations delivered before the Hunterian Society, 1819. 8, 'An Address to the Chairman and Members of the House Committee of the London Hospital, on the subject of Cholera,' 1831. 9, Desultory Reflections on Police, with an Essay on the means of preventing crimes and amending criminals,' 1785. This is an excellent essay, and contains some severe animadversions on the system of police at the time when it was published.

The materials for this notice have been chiefly selected from 'A Brief Memoir of Sir William Blizard, Knt.,' by W. Cooke, M.R.C.S.

BLOCK MACHINERY. The assemblage of machines devised by the ingenious Mr. (now Sir Mark Isambard) Brunel for the formation of the blocks employed in raising burlaths, and particularly in the important service of moving the rigging of ships, contains so many ingenious processes for guiding to the utmost amount of accuracy, and, at the same time, with the least possible labour, as to justify the opinion that it constitutes one of the noblest triumphs of mechanical skill; and, in this article, it is intended to give a brief description of the principal parts of which it is composed.

The machine may be said to consist of many saws and lathes; by these the work is performed, from the operation of cutting up a log of timber, to that of polishing the pins on which the pulleys turn; and motion is communicated to all of them by a single steam-engine.

A straight saw worked backwards and forwards, horizontally, by the engine, cuts off in succession different portions transversely from the log of timber (elm) which, for this purpose is made to rest on a table or low bench; the portions cut off being of the proper lengths for the dimensions of the intended blocks. For the smaller logs a circular saw is used; it cuts the tree transversely, and consequently its plane is perpendicular to the axis of the latter; the saw is capable of being raised vertically, or moved horizontally, in order that it may be made to enter the wood above or below, or on either side.

After the log has been cut in slices, the latter are brought to what is called the ripping saw: this is circular; and its plane standing vertically, in part above the level of the table, it serves to cut the slices into rectangular parallelopipeds. In this state the wood is brought to the boring machine, which may be thus described (the lower figure representing the plan, and the upper a side elevation):

The rectangle A B C D represents the surface of a strong table, on which is fixed an iron frame E having three legs; within these the parallelopiped F is placed between two of which appears at a, and it is rendered immovable during the operation by means of the screw b; this last being turned by the iron bar G H. c is one of the bores, which turns on its axis by means of the pulley K, the latter receiving a motion from the engine: this latter rests on the frame M N, which is capable of being moved towards the frame E by pressing on the end P of the lever P Q, so as to turn it about the pivot Q. A is another bore, which turns on its axis by means of the pulley B, the latter receiving a motion from the engine: this latter rests on the frame S T, which is capable of being moved towards the frame E by pressing on the handle U V, so as to turn it about the pivot V.

The former borer makes the hole for the pin on which the sheaves of the block are to turn; the other merely makes a perforation at a spot which is to form one extremity of the mortise intended to contain a sheave. If the block is to contain two or three sheaves, the borer is to make as many perforations, the frame S T being capable of moving in a direction parallel to B D, in order that the point of the borer may be placed where the required perforations are to be made.

A remarkably ingenious machine is employed to cut the mortises in which the pulleys are to turn; and it is hoped that the following cut and description will suffice to render the process quite intelligible. A B is a representation of the horizontal surface of the table or stage on which the block is placed; and the diagram above it exhibits a side elevation of the acting part of the machine, the pillars and braces which support it being omitted, as they would have concealed, in part, the apparatus. a is a frame made to contain the block b which, in the diagram, is but one mortise; the block is tightly fitted in this frame by means of the screw s at one extremity, and the frame is capable of being moved along the stage from s towards F, as much as the whole length of the intended mortise. The great screw C D is fixed at one extremity to the frame which contains the block, and works in a concave screw which is cut in the transverse piece F, the latter being fixed to the table or stage. E F is an axle which terminates with a crank at E and carries at the opposite extremity the fly-wheel G H, the revolving motion being communicated from the engine by
The circular motion of the crank at \( K \) produces by means of the bent rod \( L \), which turns on a joint at \( d \), a reciprocating motion vertically in the rod \( e \) which passes through a collar at \( f \); to the lower part of this rod is made fast the steel chisel \( g \) by which the mortise \( a \) is to be cut. This may be easily understood, that, if two or three mortises are to be cut at the same time, as many chisels may be fixed, in line, parallel to one another, in a frame which is carried by the rod \( e \). On the screw \( C D \) is a toothed wheel which, when it turns, can be moved round by means of the handle at \( m \); and thus a small motion may be given to the frame \( a a \) in order to bring the hole previously bored in the block vertically under the chisel \( g \). The axle \( E F \) carries an excursive wheel \( n \) (see edgeway), on the circumference of which rides one a bent lever \( p q r \), the lower branch of which lies tangentially on the top of a ratchet wheel \( r \); the inferior surface of this branch has a notch, the sides of which, by the movement of the excursive wheel, are made to act on a tooth of the wheel \( r \); and thus, the axle \( C D \) being turned, the frame \( a a \) is moved a little way towards the cross-piece \( t t \). This movement always follows immediately after the chisel has made a descent, and thus there is presented a new part to be cut out from the block. Since the screw \( C D \) is made to rotate through the block at each descent, and the movement is very rapid, the mortise is quickly made.

The extremity \( q \) of the bent lever \( p q r \) rests upon a lever whose fulcrum is at \( v \), and this rests at \( w \) on the bent lever \( s t u r v \), and when the frame \( a a \) at the notch \( y \) falls over the extremity \( z \) of a projection on the side of the frame, the notch \( y \) is lifted above the top of the wheel \( r \), and the mortise being completed, the frame with the block moves no further. The cylinder \( w \) is fixed, and inside it, \( E F \), is a cone which, while it turns with the axle, is capable of being moved backwards or forwards on the latter by means of a lever not shown in the cut: when this cone is thrust as far as it can go into \( K \), the friction is great enough to allow the axle to be turned with the fly-wheels and cylinder; but, on drawing the cone towards \( E \), its surface is disengaged from the interior surface of \( K \), so that the axle \( E F \) no longer moves with the fly-wheel. It is while the axle ceases to revolve that the mortised block is removed, and once in \( E F \) on which the operation is to be performed is put in its place.

The block is subsequently submitted to the action of a circular saw, by which the corners are cut off, and it is made to assume the form of an octagonal prism; in this state it is removed to what is called the shaping machine, in order to be reduced to the requisite figure.

The shaping machine consists of two wheels connected together and turning on the same horizontal axle: they carry between them three cylinders, of which the blocks at any distances from one another on the circumference; and at first the blocks are disposed so that the mortises in each are perpendicular to a plane passing through the common axis of the two cylinders, and the blocks being moved parallel to that axis. The wheels are made to revolve by a strap passing over a cylinder on the axle; the cylinder being in connection with the steam-engine: the cutting tool is applied, on a level with the axis of the wheels, to a horizontal frame which has the form of a circular arc; the centre being in the middle of that arc; and while the edge of the tool is pressed against the block it is slowly moved along the arc. Thus, the tool acting against the block during the revolution of the latter with the wheel, and being itself in motion horizontally, the face of the block is brought to the form of a segment of sphere. Each block is then turned on its particular axis: first one quarter round, then another quarter, and finally a third quarter round: and in each of these positions an edge or side of the block is, by the tool, brought to a form similar to that which was given to the first face; the last of the four sides being completed after each block has been turned three quarters round on its own axis. The ten blocks are then removed and ten others put in their places, to be shaped in like manner.

The blocks are not turned on their several axes by hand, the machine containing an ingenuity contrivance by which such revolutions are effected. In the following cut, \( A B \) is the axis on which the tools revolve, \( C \), of which is represented two of the radii, and \( E \) one of the blocks at the circumference. A bevelled wheel \( F G \) is fitted on the axle of the double wheel, and, in the teeth of this, work as many pinions, \( H, K, \text{etc.} \), as there are blocks; each pinion has an axle \( L M \) in the direction of a radius of the great wheel, and extending as far as the circumference of the latter; near the extremity \( M \) is cut what is called a perpendicular screw, whose threads work in the grooves of a pulley-shaped wheel \( N \), on the axle of which is the block \( D E \).

During the process of shaping the blocks, the wheel \( F G \) revolves with the great wheel, carrying with it the pinions \( H, K, \text{etc.} \), and their axes \( L, M, \text{etc.} \), the pinions not changing their places on the circumference of \( F, G \), and consequently the blocks having no movements on their particular axes.

But when the first faces of the ten blocks have been shaped, the whole machine is detached from the engine, and the wheel \( F, G \), which is capable of turning freely on the axle of the great wheel, being held fast, the latter is turned round and round, this causes the pinions \( H, K, \text{etc.} \) to move on the circumference of \( F, G \), and, at the same time to revolve on their own axes; thus the axes \( L, M, \text{etc.} \) revolve, and, on account of their connection at \( N, \text{etc.} \) with the axes of the blocks, the latter revolve also on their axes. The numbers of the teeth are so proportioned that four revolutions of the great wheel, while \( F, G \) is held fast, will cause each block to turn a quarter round on its own axis; this brings a new side of each block to the circumference of the wheel, and the whole machine being thus re-connected with the steam-engine, the process with the tool is again carried on till the new side of the block is shaped; the machine is then released from the engine, the blocks turned as before another quarter round, and there are cut on each of the faces the two grooves intended to receive the rope by which the block is to be suspended when in use: this operation is performed by means of two cutting tools, with curved edges, fitted at the opposite extremities of a small brass wheel which revolves on an axle by the movement of the latter with the same engine: the block is fixed in a frame in an inclined position, so that the cutting tools form a groove which commences near the pin-hole of the block and deepens gradually towards either extremity.

The sheaves are made of lignum vitae, and plates of the required thickness being cut from the tree, each of them has a circular form given to it by means of a trepanning, or crown saw, a cylinder of steel having teeth on one of its edges, and having on its axe a tool for boring the centre hole through which the pin is to pass; the plate of wood being fixed in its place, the workman by a lever presses the saw and centre-bit against it; and these by revolving rapidly, both give a circular form to the plate and boreed the pin-hole.

The sheave is then to be prepared to receive in its centre the metal rod or ring through which the pin is to pass; for this purpose it is laid horizontally on a plate, which may be kept at rest, or turned round on its axis, as may be required; a drill, or cutting tool, in a vertical position, is made to form in succession three semicircular excavations of small depth at equal distances from one another about the centre hole. During the cutting of each of these the plate carrying the sheave is moved; but in each interval it is turned one-third part round, by which means the tool is always carried to the centre hole to a small depth, quite round the latter; the side of the sheave is countersunk about its centre in the form of a circle having three segments cut in its circumference: the load to be carried by the sheave is always kept on the under side of the sheave. The coak, which is made of gun-metal and of a form to fit the countersink, is in two parts, one of them having a barrel which is to enter the centre hole; the parts are then introduced and riveted to the sheave. The middle part of the coak is then broached out so as to form a hole per-
feet cylindrical; and, lastly, by a lathe also connected with the engine, the groove for the rope is formed round the circumference.

The pins, which are of iron, are turned in a lathe of great strength; and are highly polished by being drawn with a revolving motion between two plates.

It should be considered as a complete description of this very ingenious and complex machinery, but our limits prevent us from going more fully through the details.

A complete assemblage of the machines was, under the direction of Mr. (Sir M. J.) Brunel, executed, in 1804, by the firm of Heineken, at Amsterdam, and a second was executed, in 1807, in the dockyard at Chatham.

BOIS, PETER OF. (Peters or Blos, P. C.)
BLOND, or BLO, JACQUES CHRISTOPHE LE, a pupil of Raphael, in Paris, 1670, known as the inventor of printing in colours. He appears to have been studying in Rome as early as 1698, and he probably lived there many years. Before 1711 he was practicing as a miniature painter with great success in Amsterdam, but he executed miniatures of so small a size that he injured his eyes, and he was forced to give up that style. Then he took to oil painting, and executed several good pictures in that style also; but he appears to have soon afterwards turned his attention to printing, and patient labor in the flat on the copper-plate, was a very much disappointed in the results. His prints were flat and dirty, and gave but very faint copies of their originals; they were however efforts of great merit and great novelty, and with many artists, they are now beloved, and much good might have resulted. Le Blond however, disinterested by the coldness with which his prints were received, and a consequent bankruptcy, neglected the discovery, and turned his attention to a new scheme—the weaving in tapestry of the Cartoons of Raphael.

His plan of printing was very simple, too simple to produce tone. He used only the three primary colours, and passed the prints three times through the press, printing with one colour each time; the secondary and tertiary colours were obtained by printing one colour over one or both of the other two primary colours; and the impression was repeated for those parts where great depth was necessary: they were first engraved in mezzotint. He published an account of his plan in 1722, in French and English, in 4to., entitled 'Le Colorio, or the Harmony of Colouring in Painting, reduced to Mechanical Practice, under easy Precepts and infallible Rules,' with five examples, and a dedication to Sir Robert Walpole. A second edition was published in Paris, in 1756, after the death of Le Blond, by one of his pupils. He published further articles in the 'Tableaux.' Le Blond executed altogether in this style thirty-three plates, many after the great masters, and all very large—some of the portraits, which are a considerable proportion of the plates. They are of two styles of colour; and the impression was repeated for those parts where great depth was necessary: they were first engraved in mezzotint. He published an account of his plan in 1722, in French and English, in 4to., entitled 'Le Colorio, or the Harmony of Colouring in Painting, reduced to Mechanical Practice, under easy Precepts and infallible Rules,' with five examples, and a dedication to Sir Robert Walpole. A second edition was published in Paris, in 1756, after the death of Le Blond, by one of his pupils.

Le Blond found also much assistance towards the completion of his undertaking regarding the Cartoons of Raphael, but it was so inadequate to the full accomplishment of the tapestries, that after he had spent all that was advanced, he saw the hopelessness of his undertaking; and in about 1778 he absconded and went to Paris, leaving his friends the partly prepared apparatus as the indemnity for their outlay. In Paris he again had recourse to his printing in colours, for which he had been distinguished by Raphael and the other great artists of the time; the enterprise failed, and he himself is said to have died in an hospital in 1741. He instructed some pupils in the art, who carried it on after his death, but with little success.

Cochin, fils, published an account of the process in an edition of Abraham Bosse's book 'De la Manière de Graver,' etc., Paris, 1768; and it is noticed in the 'Oeuvres Posthumes de Sylvain Bailly.' An artist of the name of Admiral, one of Le Blond's reputed pupils, was more successful than Le Blond, and his works are still in demand. The prints of the subject of Le Blond were of several varieties, for which it is fully applicable. He published six anatomical plates at Amsterdam and Leyden, between 1734 and 1741, and a book of insects a few years later.

(Hermeton, l'te Géne'rale d molto, Collection d'Entomop., etc.; Huber, Manuel des Amateurs, etc.; Strutt, Dictionary of Entomographers; Fiorillo, Geschichte der Zeichnenden Künstler, etc.)

BLOW, JOHN, Mus. Doc., was born at North C killingham, Notts, in 1646, and educated in the Chapel-Royal School, where he very early showed a taste for music and enterprise, for it appears, from Clifford's 'Collection,' that while one of the 'children' of that royal establishment, he composed several anthems, which had the honour to be performed before the king. His advancement was rapid, and he became the king's first musician, the principal composer of the art records; for he was successively appointed to the offices of Gentleman of the Chapel-Royal and Master of the Children; one of the King's Private Musicians; Composer to the King; and Organist of the Cluniacs of St. Paul's Cathedral, and Organist of Westminster Abbey.

Part of these duties must have been executed by deputy, and, most likely, part neglected. He died in 1708, and was interred in the Choir of Westminster Abbey, where a monument is erected to his memory, carved, by one of his famous 'Gloria Patri,' a canon, together with a long inscription, wherein it is stated, and to his honour, that he was the master to the famous Mr. H. Purcell.

Dr. Blow was remarkable for the elegance of his person and address, to which may, in some measure, perhaps, be ascribed his lion's share in the musical offices of his day. His compositions are numerous, but mere the offspring of study and patient labor. They are, however, genius. Two of his anthems however proved that he was an affectionate composer, in his 'Gloria in Excelsis,' etc., for the English College in Rome, and his 'O Pater Noster, com -posed over his art. And a few of the many secular compositions in his 'Amphiang Anglicus,'—a volume of songs, etc.—were deservedly popular during his life, and are worth revival.

The works of Mr. Blow, as published by Sir John Huber, in 1688, and a folio of his anthems, which so with what integrity he could redeem a benefit to the court to which he belonged, and whom he viewed as the enemy of his religion. In the chapel of James II., an anthem, by some Italian master, had been introduced, which the king, liking very much, asked Blow if he could make one as good. Blow answered in the affirmative, and the next Sunday produced the fine anthem, 'I beheld, and lo a great multitude.' When service was over, the king sent Father Petri to tell the author that he was much pleased with it. 'But,' added the popular composer, 'I myself think it too long.' 'That,' answered Blow, 'is the opinion of but one fool, and I heed it not.' The Jesuit was so displeased at this unceremonious assault, that he determined on revenge, and persuaded the king to put the composer under suspension; from which however he was soon released by the Revolution, which took place shortly after.

BLOWING-MACHINES, or machines for producing a current of air for the purpose of exciting the requisite intensity of combustion for metallurgical and other operations which require great heat, are a class of contrivances only slightly alluded to in the article BLOWING (P. C., p. 188), but which, from their great importance and very general use, demand further explanation.

The kind of blowing-machine to which the name of bellows is usually applied consists of a air-tight chamber of variable dimensions, having one aperture closed by a valve which can open only inwardly, or another, which is constructed either directly or indirectly with the nozzle, or pipe for the exit of the current of air, closed by a valve which can only open outwards. When, by the application of mechanical force, the chamber is distended or enlarged, the pressure of the external atmosphere opens the valve which closes, and when the chamber becomes filled with air; but when, by an altered application of power, the chamber is compressed so as to reduce its capacity, the condensation of the included air causes the valve to close, and the air is forced outwards to open, so that the air escapes by the nozzle, with a degree of force and rapidity proportionate to the pressure employed in compressing the chamber. The leather bag of the musical instrument called a bagpipe is an example of such a variable, or expandable and compressible, and the wind would therefore, if fitted with a nozzle, form a substitute for the common domestic bellows; but the same effect is produced, in a much more convenient way, by the use of a chamber formed of two bags, which are connected so that the air is leathered in folds in such a manner that the upper bag may be raised or depressed at pleasure, while the lower bag remains stationary. Of the precise arrangement of the parts alluded to in hand-bellows for domestic use it is unnecessary to give an account; but we may here mention some of the principal modifications of form and arrangement in large bellows employed for forge-fires and furnaces.

The blast produced by such a machine as has been de
served is intermittent, and also variable in intensity. The first of these defects may be remedied by the device mentioned in Bellows, P. C., of employing two or three separate bellows, or pairs of bellows, worked alternately, so that the one may be expelling air while the other is drawing in a fresh supply. While, however, the blast thus produced is continuous, it is by no means equal in force, to remedy which the air expelled from the chamber already described should be forced into a second chamber also of variable dimensions, but compressed by a weight so as to produce a constant steady pressure, and the nozzle should be made to open into the second chamber. In forge-bellows of this construction there are three boards, connected by leather sides which are kept in regular folds by hoops of cane. The middle board is fixed in a horizontal position, and has the nozzle attached to it, while the upper and lower boards are moveable, and loaded with weight, which is that which is with the bellows, the chamber formed between the upper and the middle boards is collapsed, while that between the middle and the lower boards is distended and full of air. When in use the lower board is raised by means of a lever and chain, and the air induced between it and the middle board is forced through a valve into the upper chamber; and by the rapid repetition of this action the upper chamber is filled with air more rapidly than the nozzle can carry it off, so that the upper board rises. The weight of bellows may then be adjusted to a continuous and equable blast will be maintained by the pressure of the loaded upper board until it has, by the complete expulsion of the air, descended to its original position. It should be remembered that this perfect equability of blast is only maintained while the working of the bellows is suspended, because during that time the blast is produced solely by the pressure of the loaded board; while, during the working of the bellows, the pressure alternates between that of the superior pressure produced by the influx of air from the lower chamber, whereby causing the upper board to rise and fall with each stroke. Many smiths' bellows are made of the pear-shaped form common to hand-bellows, and have the boards, or at least the lower and middle boards, united by a kind of hinge-joint; but the superior machines of this description have the boards circular, and the working apparatus so arranged as to make their action parallel; and in some cases, as for portable forgings, helical springs are applied to the boards in lieu of weights.

Beckmann, in an article on the invention of bellows (History of Inventions, English edit. of 1814, vol. i. p. 105), observes that large bellows, such as were formerly used in smelting-houses, when made with leather, were attended with much of hinge-joint; but the superior machines of this description have the boards circular, and the working apparatus so arranged as to make their action parallel; and in some cases, as for portable forgings, helical springs are applied to the boards in lieu of weights.

Beckmann, in an article on the invention of bellows (History of Inventions, English edit. of 1814, vol. i. p. 105), observes that large bellows, such as were formerly used in smelting-houses, when made with leather, were attended with much of hinge-joint; but the superior machines of this description have the boards circular, and the working apparatus so arranged as to make their action parallel; and in some cases, as for portable forgings, helical springs are applied to the boards in lieu of weights. In this figure a represents a wooden box of an oblong square form, the upper edge of which is indicated by dotted lines. It is open at the top, and from one end of it proceeds the nozzle b, which, as well as the bottom board of the box, is supplied with a flap on the sides, and so forms a nose which will bear a horizontal position, and is covered by the box c, which is open at the bottom, and is so much larger than a as to allow the upper box is capable of being worked up and down by the projecting handle e. Great friction would be occasioned if an incorrect and not maintained. A certain number of the boxes are made to be placed one after another, and to be fixed by a close-fitting, and not maintained. A certain number of the boxes are made to be placed one after another, and to be fixed by a close-fitting, and not maintained. A certain number of the boxes are made to be placed one after another, and to be fixed by a close-fitting, and not maintained. and form which it is conducted to the blast-pipes, which are called tuyeres or tees. Barlow, in his 'Treatise on Machinery and Manufactures,' part of the Encyclopaedia Metropolitana, describes a very powerful blowing-machine at Woolwich Dockyard, in which four cylinders supply air, at a pressure sufficient to conduct the air-chest from which pipes extend to all the forges and fires in the smithy, the pipes being supplied with cocks by which the blast can be turned off or on at pleasure. To ensure equal pressure in all the cylinders, air is first caused to pass into air-pipes exceedingly compressed with opening into a safety-valve. Owing to the use of sliding instead of clack or flack-valves in the blowing-tyves, this machine works very quietly. Another mode of regulating the blast is to throw the air from the cylinders into a large iron box inverted in a cistern of water, and somewhat resembling a gasometer, but so fixed as to be incapable of more partial discharges and therefore of the condensation of air in the box is to force some of the water out, and the difference between the level of the water within and without the box forms a measure of the degree of condensation or pressure. In using such an apparatus care must be taken to conduct the air-pipes at so high a level as to render the forcing of water into the furnace impossible. The blast thus produced is exceedingly cold, which is a great disadvantage in a smelting-furnace. For a notice of the advantages of a hot blast see Bellows, p. c., and their application to steam-carriage furnaces is alluded to in Stearn-Carriage, P. C., p. 401.

BLUMENBACH, JOHANN FRIEDRICH, was born at Gotha, on the 11th of May, 1752. He studied medicine, and succeeded in 1776 of the foundation of many of his important investigations on this subject in after-life, and led to the formation of his collection of the skulls of all nations, which is one of the most extensive in existence. New editions of this dissertation appeared in 1776, 1778, and 1755. In the last edition a letter was added, addressed to Sir Joseph Banks, on the subject of some mummies which had been opened in London. The last edition of this work was translated into German by Gruber, in 1799, and into French by Chardel, in 1804.

In 1776, the year after taking his degree, Blumenbach was appointed extraordinary professor of medicine in the University of Gottingen, and in 1779 he was made ordinary professor. At the same time he also received the appointment of superintendent of the library and museum of natural history in the university. From this time his contributions to the sciences connected with medicine, especially anatomy and physiology, became more frequent. In physiology he pursued the work of Haller, and directed his attention especially to the structure and functions of the lower animals, as a means of determining the true laws of human physiology. After the publication of his inaugural dissertation, his next work was an anatomical essay, entitled 'Ueber die anthropologischen und physiologischen Merkmale der Natur in der menschlichen Körpervarietät,' 8vo., Gottingen. In this work he threw much light on the obscure subject of generation, and opened up a path for future inquirers. New editions of this work appeared in Germany in 1759 and 1791. It was translated into Dutch in 1790, and an edition, translated by Sir Alexander Crichton, appeared in English in 1792. In 1793, the work was translated into French and the title 'Histoire de la Formation des espèces, par voie naturelle,' 8vo., Gottingen. Mr. Crichton, in his translation of this work, was appointed 'Superintendent des Editions de la Bibliotheque de la Societe Medicale de Paris,' 8vo., Gottingen. He also published, in Lith., in the same year, an introduction to medical literature, with the title 'Introduction a l'Historie des Sciences, etc.,' 4to., Gottingen.

In the year 1787 he published his 'Institutiones Physiologice,' 8vo., Gottingen. This work was written in Latin, and was one of the first attempts that had been made to form a connected and comprehensive view of the whole system of medicine, without entering into the minute anatomical structure of the body. It quickly became the text-book of schools where physiology was taught. German translations by Eyster, 1790, and also by Crichton, 1795. His most important original work was published in 1798, 1810, and 1821. It was translated into Dutch by Wolf, in 1791, and again by Voesen, in 1808. An English edition, translated by D. Caldwell, appeared at Philadelphia in 1795. A French translation, by Pigenet, appeared in 1797. A second English translation, by Dr. Elliotson, was published in London, in 1817. A second edition of this translation was published in 1818, and is remarkable as being the first work that was ever printed by steam-machinery. Several subsequent editions of this translation appeared with copious notes by the translator, and these at last were so numerous, and the progress of physiology required so much of the original to be modified, that the last edition of the work, which appeared under the title 'Human Physiology, &c., with which is incorporated much of the elementary part of the Institutiones Physiologice of J. F. Blumenbach, by John Elliotson, M.D.'

Blumenbach, in all his contributions to physiology, had frequent recourse to the lower animals for the purpose of illustrating and developing the functions of those of the higher; and in 1805 he was induced to publish a manual of comparative anatomy. This work appeared at Gottingen, with the title 'Handbuch der vergleichenden Physiologie,' and an English edition of it appeared, in German, in 1815 and 1824. It was translated into English in 1806, by Dr. William Lawrence, surgeon, who, after John Hunter, was one of the earliest cultivators of comparative anatomy in connection with the study of medicine in this country. It was translated into French by Mr. Coulorison, and published in 1827. Although this work is meagre compared with those which have appeared since it was published.
BOBBO 210

The province of Bobbio is about 25 miles long, and about 10 miles wide. It is divided into four mandanici or districts: Bobbio, Ottonne, Vars, and S. Stefano. In all 27 communes, and about 32,000 inhabitants. The valleys produce corn, Indian corn, wine, and fruit. The mountains are partly covered with forests. Farms are mostly small. Sheep and pigs are numerous; the horned cattle is scanty and the poultry is not numerous. Bobbio is the most important town of the province. Many of the inhabitants emigrate to the plains to earn their subsistence.

Bobbio, the head town, is situated in a valley near the tenth mile, and is about 50 miles from Rome. The town is divided into many small sections, and is surrounded by the town of S. Stefano, which is about 4 miles in circumference. The town is less than 1,000 inhabitants. Besides the cathedral, the church and former convent of St. Columbanus are deserving of notice. The church is a vast and handsome building. The church, which is now a parish church, is large; it has 21 altars, some good trecei altar-pieces, and a substantial vault in which several of his discipies are buried. The church and convent were first built about the end of the sixth century, but they have been rebuilt or restored at various times. The well-known library, rich in valuable and rare MSS., among which were several palimpsests, has been distributed among the libraries of Milan, of the Vatian, and of the Turin university. The other buildings deserving of notice are the ancient cloth hall, the town hall, and the episcopal palace. There is another Bobbio in the Sardinian states, in the district of the Valdenses near Pigner.

BOERNE, LUDWIG, was born in 1784, of Jewish parents, at Frankfurt on the Main, where his father, Jacob Baruch, was a banker. After having received his preparatory education in his native place, he went to the university of Berlin, and afterwards to that of Halle, where he studied medicine, though against his will, for as persons of the Jewish persuasion cannot hold any public office in Germany, the only scientific department that can devolve upon him with any hope of advantage to themselves is medicine, which they are allowed to practice. In 1807 however he gave up his medical pursuits, and in the university of Heidelberg he began to study politics and political economy, which he continued at 1808 at Giessen. On his return to Frankfurt, which was then in the hands of the French, he received an office in the department of the police, which he held for several years, although it little agreed with his peculiar views. In 1815, when Frankfurt recovered its old constitution, Boerbe, being a Jew, was, of course dismissed from his office, but received a pension. Having thus got rid of all external ties, he now began to devote himself with energy and great success to what he conceived to be his calling: he became a political writer, successively published three 'Untersuchungen' (Casalis, Staats-Ristretto, Diet Zeitschungen, and Die Wapse), which were published at Offenbach, and to which he himself contributed some of the best of the political essays and literary criticisms written in the age of the French revolution. These periodicals were of too liberal a nature, the government of Hesse-Darmstadt suppressed them, and Boerbe himself was soon after arrested at Frankfurt, and charged with having promulgated revolutionary ideas. He was tried as a Jew, but as no evidence was brought against him, he was acquitted, and declared perfectly innocent. In 1817 Boerbe exchanged his Jewish religion for Protestantism, and altered his name Baruch into Boerbe. After having given up 'Die Eiche', he lived in the service of the French Republic. In 1818 he was employed in the army of Silesia, and in 1819 in the army of Italy, where he served as a journalist in the Sambre-Meuse. In 1820 he was appointed to the government of the city of Heidelberg, and in 1823 to that of the city of Strassburg. In 1825 he was appointed to the government of the city of Strassburg, and in 1829 to that of the city of Strassburg. In 1830 he was appointed to the government of the city of Strassburg, and in 1835 to that of the city of Strassburg. He was a man of great learning, and was esteemed by his contemporaries as a great man of letters. He was a man of great learning, and was esteemed by his contemporaries as a great man of letters. He died at Paris, in 1836.
Mr. Hardcastle, Dr. Waugh, and the Rev. Matthew Wilks, founded Paris for the purpose of promoting measures which had long been attempted for the diffusion of the Christian faith, and religious works into France, and in furtherance of which object he had written his ‘Essay on the Divine Authority of the New Testament,’ a work which, in addition to being very widely circulated in France and England, was soon translated into Spanish, Italian, and German. A copy was sent to Bonaparte while at St. Helena by the dowager Lady Grey, and, after his death, was returned to the author with some marked approval by the emperor. In 1816, in conjunction with Dr. Bennet, Bogue undertook the benevolent missionary tour, for the promotion of the cause of missions in the Netherlands; and during the remainder of his life he was continually engaged in efforts connected with the work which lay nearest his heart. Very soon after, when upon one of his numerous preaching tours for the Missionary Society, he was taken ill at Brighton, where he died on the 25th of October, in his seventy-sixth year. His remains were removed to Alvesford near Gosport, and interred with extraordinary marks of respect.

In 1815 the diploma of Doctor of Divinity was conferred upon Bogue, by Yale College, North America; and it has been stated that the same was offered by the university of Edinburgh, but Bogue did not accept it. He was keenly interested in the anti-Jacobin sentiment at this period, and his humorous writings did not always win the favor of his readers, but his works were received with much interest, and his character was a subject of critical discussion. He was a lover of the French language, and his works were soon translated into it, even in his published works. In addition to his intimate connection with the London Missionary Society, Bogue was one of the originators of the ‘Tract Society’ of the Church of England. The first tract issued by it was Bogue’s ‘Short Essay on the Character of the Public Mind.’ Besides various minor works, he published discourses on the Millennium, and in conjunction with his pupil and friend, Dr. James Bennett, a ‘History of Dissenters, their rise and revolution in England, from the year 1808,’ in four volumes, 8vo., 1818-1819. A second edition, somewhat condensed and re-arranged, was published in 1833, in two 8vo. volumes, by Dr. Bennett, who has written a continuation of the history as a separate work. Dr. Bennett has published a lengthy memoir of Bogue, and there is a very full account of him, containing some additional matter, in Dr. Morison’s ‘Fathers and Founders of the London Missionary Society.’ A brief French memoir in the ‘Archives du Christianisme’ for 1836 was reprinted at Paris as an 8vo. pamphlet. Bogue, the sculptor, has executed a bust of Dr. Bogue, from a posthumous cast, which conveys a good idea of that remarkable depth and solidity of character which led the French police, on occasion of his visit to Paris, to describe it as the ‘image of the public mind, characterized by what they termed “profundeur.”’

BOHLEN, PETER VON, late professor of Oriental literature in the university of Konderberg, was born on the 15th of March, 1735, near his heart, in the autumn of 1786, and was twelve years old, and it was thought necessary that he should learn some trade; he was put apprentice with a village tailor, in whose house he was obliged to do the lowest and meanest work, and that he might, as soon as possible, become a master and husband and wife; he was ill-used by his master and his querulous wife in a manner which afterwards related with shuddering, and he used to wonder that under such circumstances he had not been killed long before. In 1810, his father, an appleboy, for his honest labor, was caught and abused by his master, and he was the same, being unable to bear anything, sent to a prison for two weeks, and during that time was called upon to appear at Jever to be examined as to his fitness for serving in the army of Napoleon. He was delighted at the prospect of getting away from his master and of seeing something of the world.
found to be too short, and was obliged to return to the tailor. Some time afterwards he was called upon again, and was admitted into the army. At the examination the French general Guison took an interest in him, on account of the cheerfulness with which he appeared under his new life. Guison gave him some money, and permission to go and take leave of his friends. Bohlen, on his return, remained with the general in the capacity of servant; and in 1812 he accom-
mpanied him to England, with whom was engaged to go to Hanover, from which place frequent excursions were made to the neighbouring towns. Afterwards they travelled to Stuttgart, Switzerland, and Berlin. General Guison gradually ceased to demand any services of Bohlen, and treated him with more affection, and he received, in 1815, when the French army returned from Russia, Guison and his corps retreated to Magdeburg. Bohlen afterwards accompanied the general to Hamburg. At this time however the relation between them was not so firm, and in 1817 Bohlen became the Frenchman became more harsh and severe, and the young German, forgetting the kindness he had received, lost no opportunity of showing his obstinacy and his avarice to the French. During the siege of Hamburg Bohlen opened and read a note of great importance, which he had to carry to Fromont, the general's adjutant; and had it not been for Fromont's attachment to Bohlen, he would have paid for his curiously and indiscretion with his life. Fromont at length procured a situation for him to Adolphe Hermite, but he did not remain with the admirals above two months. Early in 1814 the French quitted Hamburg; and Bohlen, although he had nothing to live upon, refused to accept any other employment. He remained at Hamburg; he first lived for some time with a poor ferryman, who wanted Bohlen to engage in his own trade; but a black cook of Admiral Hermite, who had likewise remained at Hamburg, prevailed upon him to seek a place as waiter in an hotel. This was soon found; but the incessant work and the want of rest was more than he could bear; he accordingly left his place, and engaged himself as servant to a rich India merchant. As he had not much to do in his new situation, he got his master's clerk to instruct him in letter-writing and the like, and employed his time in reading. In the mean time he acquired a passion for writing poetry. He had the satisfaction of seeing his poems printed; and as some persons went so far as to compare him to Klopstock, his head was almost turned by his success. He had learned to speak French in his intercourse with Frenchmen, and he now learned English in the same way; for in the house of his employer scarcely any other language than English was spoken. He then began translating Burns into German; and, with the assistance of a dictionary and grammar, he even ventured upon translating Virgil. He next made an attempt to get admission into the gymnasium of Hamburg, but was refused, on the ground of being too old. In 1817 he moved to Berlin, and Bohlen again as poor as before; for he had never claimed his full wages, but only taken as much as he wanted at the time. Another attempt was made to get into the gymnasium; and the support of several benevolent men at length succeeded in getting him a place of scholar, and he became a pupil of the Johanneum at Hamburg. His diligence was extraordinary, and his conduct secured the good will of all. The gifts of benevolent friends, and private lessons which he began to give, procured him the means of living. His intention was at first to study theology; but the preparation that he made for it, the study of Hebrew, Arabic, and Persian, led him in another direction. About this time he was induced by his master to take the Greek name of Bohlen; he remembered however that his father was descended from a noble family.

In 1821 he went to the University of Halle, some distinguished and wealthy Hamburger having promised him with the other many others of lectures on Oriental and classical literature. At the suggestion of Gesenius, Bohlen copied, translated, and upon, an essay upon the Hebrew language, which was sent to the Prussian ministry for the purpose of obtaining assistance from the Prussian government to continue his studies, and of paying the way to a future appointment in Prussia. While he was in Halle, he left his family. Von Bohlen published a little work, 'Syntaxis ad Interpretationem Persica,' which was well received; and in the autumn of the same year he went to Bonn, to study Arabic under Freytag. Here he wrote a dissertation on the life and character of Motenabbi, which received the prize, and was printed at Bonn in 1824; it was very well received by those acquainted with the literature of the Arabs. In the mean time he continued his studies of the Persian language, and in 1824 he began that of Sanscrit. He had learned Italian and Spanish. Towards the end of this year the Prussian ministry summoned him to Berlin, that he might complete his studies there, and prepare himself for a profes-
sional life. Bohlen was appointed as assistant to Dr. Rosen. At Berlin he attended the lectures of Bopp, and formed an intimate friendship with the late Dr. Rosen. In 1826 he went to Königsberg to begin his career of academical studies, and was engaged, in the usual way, as a private lecturer. He received however, from the first, a salary of 200 gulden. In 1826 Bohlen was appointed professor extraordinary. In 1827 he travelled to Bonn, and married a lady whose acquaintance he had made during his stay there; and the year after he was appointed professor adjunction, on the recommendation of the Orientalist, which the Prussian ministry placed funds at his disposal. He was also provided by the government with Arabic and Devanagari types, and printed with his own hands the 'Carmen Amali.' Soon after he published his great work on Indian antiquities, 'Chrestomathy Persica,' which, in its portions and sub-
jects, is one of the most valuable books on ancient India; and no attempt has yet been made to supplant it, though Lassen's great work on the antiquities of India, which is now in the course of publication, is very splendid. In 1831 Bohlen returned to Bonn. In 1837 he undertook a second journey to England. He stayed some time with the son of the Marquis of Landzourne, and pursued his Oriental studies with his friend Dr. Rosen. On his return to the Continent he travelled with his wife to the south of France and Italy, for the benefit of his health. Bohlen's health also was in such a precarious state that his friends advised him not to return to the north. He therefore remained at Heidelberg and Bonn for some time, and then went to Halle. He has since resided in that town for the last 24 years, and has been the most active member of the society. In 1859, from this blow he never recovered. He was unable to return to Königsberg, and remained at Halle. In the beginning of 1840 his condition became worse, and he died on the 6th of February at Halle, where he was buried.

Bohlen appears to have been a most amiable man; and in his autobiography, from which this account is taken, he relates without any reserve all the vicissitudes of his life, in a manner which secures the affection and admiration of every reader. His character appeals to have been very much that of his friend Rosen. In 1826 he was elected a member of the Royal Asiatic Society of London. He possessed a most extensive knowledge of Eastern history and literature, and his works as an Orientalist are valuable, not only for their accuracy, but mainly from two causes; first, the great haste with which he worked, and secondly, a want of sound philological know-
ledge, for which he had little taste; though in later years this defect greatly impeded his antiquarian researches, as he himself confessed. He was never a great number of his own writings and reviews which Bohlen wrote for the leading journals of Ger-
many, and shall merely subjoin a list of his separate works: 1. 'Symbolae ad Interpretationem Sac. Cod. ex Lingua Persica,' Leipzig, 1822; 2. 'Commentatio de his bookio,' celebrating the Arab Poeta,' Bonn, 1824; 3. 'Carmen Arabicum, Amali dictum,' Königsberg, 1825; 4. 'Vermischte Gedichte und Gebwerzungten,' Königsberg, 1825; 5. 'De Buddhismos Textu,' Halle, 1821, 6. 'Indische Verzeichnisse mit bearbeitet,' 2 vols., Königsberg, 1827; 7. 'Bhartrihis Sanscrita et Carmen Chauroupachas,' Berlin, 1833; 8. 'Die Genesis, historisch-kritisch erlautert,' Königsberg, 1835; 9. 'Die Sprache des Bhartrihis,' metric Leipzig, 1838; 10. 'Die Sprache des Vedas,' metric Halle, 1839; 11. 'Die Semitische Sprache in ihren Untersuchungen,' metric Halle, 1840; 12. 'Bhartrihis Sanscrita et Carmen Chauroupachas,' Lips, 1840. Bohlen was a contributor to the Penny Cyclopaedia, for which he wrote the articles LOKMAN, MAHAMATAM, MAHMUD OF BAGHDAH, and MOHAMMED (including KORAN), MONGOLS AND TARTARS.

BOIE, ADRIEN, OIS, A French com-
poser, born at Saint-Denis, in the department of Val-d'Oise, in 1775. At a very early period of his life he manifested a most decided talent for music, and at eighteen wrote a one-act opera, which was produced at the theatre of his
BOI 213  BOL

native city, and drew all the amateurs of Normandy to hear it. In 1798 he went to Paris, and brought out several compositions, of which many met with great success, and some are still performed. In 1800 he was appointed to give a course of concerts at the Opera Comique; and this was speedily followed by others. In 1800 he wrote three operas,—Benbowski, 'Le Calife de Bagdad,' and 'Ma Tante Aurèle,' all of them abandoned, for the audience were inferior to the music, and the stock pieces. On the establishment of the Conservatoire of Music, by the National Convention, Boieldieu was appointed one of the professors. In 1803 he accepted the Empress Alexander the appointment of Maître-de-Chapelle at the imperial Court of Moscow, for five years, and governed for one season at the Theatre de la Ville, and some other rank operas, and various smaller dramatic works. In 1811 he returned to Paris, and there, among other operas, produced 'Jean de Paris,' 'Le Petit Chaperon Rouge,' and his grand masterpiece, 'La Fille de Madame Blanche.' He afterwards was called upon to compose music for the baptism of the Duc de Bordeaux, and the coronation of Charles X. After this, the state of his health indicating the want of some repose, he proceeded to a watering-place in the Pyrenees, and appeared to be much benefited by his retirement and relief from business and care; but soon after he was suddenly attacked by illness, and died, October 3rd, 1836, after a very short confinement.

With the sudden and splendid public funeral, which was, in some degree, a military one, for he was an officer of the National Guard, and held the order of the Legion of Honour. Mass was celebrated in the grandest manner in the Église des Invalides, and his remains were then placed a magnificent monument, rising into the sky, of this very clever composer was claimed by the city of Rouen, and received with great pomp in the cathedral, which was magnificently decorated for the occasion, the council of the town having voted 12,000 francs to defray the expense of the solemnity. They also erected a column to the memory of their distinguished countryman; and the government settled a pension on the son of the composer, M. Adrien Boieldieu.

Boileau is the general name applied to vessels, whether close or open, in which fluids are exposed to the heat for the purpose of ebullition or evaporation; but the term is most commonly applied to the close vessels used for the generation of steam. Such boilers, to lessen the danger of explosion, are almost invariably made of wrought metal, which, if burst, will bear rather than fly to pieces, as cast metal would do; and the plates made for the purpose are formed of the best and toughest metal, and rolled or wrought with peculiar care. Engineers differ as to the comparative merits of iron and copper as a material for steam-engines, but the bolder admit that iron, when of good quality, has the greatest cohesive strength, although the greater uniformity of texture in sheet-copper renders it safe to construct-copper boilers of less dimensions. In 1773, Antonioli, in 'Dissertation on the subject of iron' published in 1773, gave his opinion that iron was essentially better than copper. Further than this, supposing an explosion to occur with a copper boiler, it is likely only to produce a rent or tear in the metal, while an iron boiler, even though wholly of wrought plate is frequently broken to pieces. The cost of copper is about four times that of iron, but, as, owing to its far more rapid transmission of heat, a copper boiler may be made considerably smaller than an iron one to produce the same quantity of steam, and may therefore be still further reduced in this respect and weight without impairing its strength; the cost of a copper boiler is nearer twice than four times that of an iron boiler of equal evaporating power; and, as a set-off to this increased expenditure, the value of the old copper, when the engine is broken up, is far greater than that of the old iron, while an old iron boiler is worth little more than the cost of removal. Steam-engine boilers are treated of under Steam-Engine [P. C., p. 482-484], Steam-Carriage [P. C., p. 490], and Steam-Vessel [P. C., p. 608], and those of railway engines are treated of by Boulton and Watt in their 'Improvements in Steam-engines' in 1775. It is possible that such an opposition as the one between Quadra and Stirling, and such readers as may wish for further information respecting the various schemes which have been devised for remodeling the real or supposed defects of ordinary boilers or steam generating machinery, will find the manufactures in this book. 'Boiler' in Heber's 'Engineer's and Mechanic's Encyclopedia.' Boilers for the production of steam or the heating of water for the purpose of warming buildings are noticed under Warming and Ventilation [P. C., pp. 99, 70].

The excellence to which this art has now attained is such that the manufacturing operations, one of the most important is that employed, under the name of Howard's Vacuum-Pan, for boiling sugar at a lower temperature than in the open air, by the formation of a partial vacuum. A representation of this apparatus is given under Sugar [P. C., p. 232].

BOL, FERDINAND, a very able portrait painter and etcher, born at Linz, 1722; and died at Antwerp, 1790.

He was the pupil of Rembrandt, and executed some portraits in his style, of equal merit. He painted also some historical pieces of great merit, which are at Amsterdam, but his works were but few. He died rich, at Amsterdam, where he principally lived, in 1786, advanced in years. He etched also sixteen spirited plates.

(Houbraken, Schouburgh der Kunstschieders, &c.; Bartsch, Catalogue Raissonné de l'Œuvre de Rembrandt, &c.; Heineken, Dictionnaire des Peintres, &c.)

BOLOGNA, JOHN OF, or GIOVANNI DA, a celebrated sculptor and architect, born at Douay in Flanders, about 1594. He went early to Rome, where he distinguished himself by his masterpieces. Though a Presbyterian, he is known only by the above name. Van Mander calls him Jean de Bologne, yet he lived the greater part of his life at Florence. Van Mander probably knew only that name by which he was called by Vasari, who speaks of him as Giovanni Bologna, or Giovanni Bolognese. It is a narration of some he seems to have acquired from his celebrated fountain at Bologna, of which the crowning colossal bronze figure of Neptune is one of the masterpieces of modern sculpture.

He was selected also by the Academy of Florence, and was also sculptor to the grand-duke Francesco I. In 1606 he was invited to Genoa, where he executed several admirable works, chiefly in bronze. He died at Florence in 1608, aged eighty-four, or, according to a note in De Yonge's edition of Van Mander, only seventy-nine, for it is there stated that he was born in 1558. Baldwin, the chief authority for the life of Bologna, mentions in a body of his article, that he died in August, in 1608, a few months before his bronze equestrian statue of the grand-duke of Florence, Ferdinand I., was fixed in its place; yet in the heading of the article it is said that he died in 1599, an inconsistency probably due to the editor. John of Bologna is the sculptor who, when he showed to Michelangelo, whilst at Rome, a carefully finished model, was told by the latter to learn to sketch before he attempted to finish—a precept which he did not forget. John of Bologna, with the exception of Michelangelo, surpassed all the sculptors of his age, or indeed of the sixteenth century, and was surpassed Michelangelo himself in proportion and execution. His Rape of the Sabines is a magnificence of three centuries, and his figures, bearing the woman away in his arms, and striding over a fallen Sabine. Andreaus has cut three excellent views of it in chiaroscuero, in wood; Louis XIV. had it cast in bronze.

(Vasari, Vie de Pittori, &c., ed. of Lenghor; Baldinucci, Storia dei Professores del Dizionario, &c.)

BOLSover STONE. The yellow limestone of Bolfow in Derbyshire is used in the construction of the new Houses of Parliament. It was selected for its durability, strength, fitness for ornamental work, and colour. It is quarried at Newchapel, near the Derwent river, and is a carbonate of magnesia with carbonate of lime, in small granular crystals, without the slightest trace of organization, flinty nodules, or other blemishes. It has been subjected to various severe operations, and has been subjected to the most severe operations, and has been tested with credit; but it is yet to be seen whether it can withstand the atmosphere of London, where it has destroyed the Bath and Portland colts.

BOLSwerk, SchelTius, a designer and very celebrated engraver, was born at Oirschot in Friesland, in 1596. He lived and worked chiefly at Antwerp, with his elder brother Boetius. His best works are after Rubens and Vandyck, after whom he has engraved several admirable works on a large scale. He was born in 1596, in the art of engraving. Boets is said to have examined and touched with the crayon all the proofs of Bolswert's engravings after his works. Bords's prints are distinguished as true works of art, not as mere excellent mechanical performances of the graver; and they are admirably drawn, various and true in their effects of colour, and effective in light and shade; he preserved also the characteristic style of the master after whom he engraved. He
was equally excellent in portrait, history, and landscape. 

BONAPARTE, Joseph, Napoleon's elder brother, was born in Corsica in 1768. He received his education at the college of Autun in France. After the death of his father, he re-

BONAPARTE, Letizia RAMOLINO, born at Ajaccio in Corsica, in August, 1776, married in 1797 Charles Bonaparte, a landed proprietor and a lawyer. Charles left under Paoli for the independence of the island against French and his young wife accompanied him through their mountain expeditions. The family are named under BONAPARTE, NAPOLIS, F. C.

After her son Napoleon became First Consul of France, Madame Letizia fixed her residence at Paris where she lived rather retired, but after the empire was proclaimed and the title of Madame Mme had her own household, her chamberlains, ladies of honour, and all the accessories of a court. Des Casess was appointed her secretary. Her half-brother Fesch had been made a cardinal. Madame Mme was afterwards murdered by her financial mismanagement in her expenditure, and she is said to have once observed that perhaps some day she would have to support out of her savings all these kings, meaning her sons. She was des-

...
named to Corsica in 1785. He applied himself to the study of the law, according to his father's wishes. In 1792 he was made a member of the new administration of Corsica, under Paulii, who was an old friend of the Bonaparte family. In the 1793, he was a member of the Legislative Convention, and called the English to his assistance. Joseph emigrated to Marseille, where lie married one of the daughters of a wealthy banker of the name of Clari, without ever resuming his seat, to which he was appointed by the English. Joseph repaired to Paris, from whence he was shortly after sent by the Executive Directory as ambassador to the pope. There was then at Rome a knot of enemies who were bent upon establishing a Roman republic, and they relied upon the countenance and support of the French. On the 28th of December (1787) they assembled to the number of about three hundred, under the guidance of a sculptor named Cersacchi, and proceeded to the palace Corsini, where Joseph Bonaparte resided, vociferating 'The Republic and the Roman people for ever!' and they applied to the ambassador, claiming French protection. Joseph desired them to leave the palace. In the mean time a detachment of the guard, who were on the various duties of the day, came to the palace, and insisted that the insurgents should leave the premises. Those from within insulted and taunted the soldiers, who at last rushed into the court of the palace to clear it of the fugitives. Some say that the soldiers did not enter the palace, because they were insulted, but Napoleon himself denied it. Joseph, attended by Generals Duhopt and Sherlock, came down the staircase to remonstrate with the pay officers, but could not make himself heard in the midst of the confusion, when Duhopt, young and impetuous, drew his sword, and rushed forward, followed by the insurgents, in order to drive away the soldiers. The soldiers then fired, killing several of their opponents, and Duhopt among the rest. The insurgents dispersed in the gardens of the palace, and the King himself was surrounded with just cause. The transactions were much misrepresented by the French and their partisans. Joseph wrote in a vehement strain to the Cardinal Doria, secretary of state, complaining of the violation of his residence, and requiring immediate satisfaction. The cardinal hesitated; Joseph demanded his passports, and, heedless of the explanations sent by the Roman government, he set off in the night of the same day to return to France. The Directory then ordered Berthier to take possession of Rome.

Joseph resumed his seat in the Council of the Five Hundred, and, during the absence of Napoleon in Egypt, he and his brother Lucien prepared the way for his return, and for the establishment of the First Consul, made Joseph councillor of state, and he employed him in September, 1800, to negotiate a treaty of peace and commerce with the United States of North America. Having exhibited some diplomatic skill in this transaction, he was sent in the following year to Lunéville, where he concluded a treaty of peace with the Emperor of Germany in 1801, and the next year he was likewise employed at Amiens to negotiate the treaty with England. He was made a senator, and on his brother's abdication imperial crown. Joseph was recognised as an Imperial Prince and Grand Elector of the Empire. It is said that his brother offered him, in 1804, the crown of the kingdom of Italy, but that Joseph refused, unless it was made independent of the crown of France. When Napoleon sent an army to invade Naples, at the beginning of 1806, he appointed his brother, 'Prince Joseph,' to lead the expedition, Marshal Massena acting as military commander. A few months after, Napoleon appointed by a decree his brother to become resideant under his own name in Sicily. Joseph resigned in Naples, though not in Sicily, little more than two years. The character of his administration is given in the History of Naples, by Colletta, a writer by no means prejudiced against the French rule. Acting as his brother's lieutenant, when Napoleon had taken the Island of Elba, Joseph raised himself into a cadastre, or survey and estimation of the landed property, for the better assessment of the land-tax; and he established a new and regular system of provincial administration. He also embellished the capital, began new roads in the provinces, and organised an effective gendarmerie to repress the robber bands in the provinces. Most of these measures were directed against the overbearing manner, like all the reforms made under Napoleon, and many individual rights and interests were overlooked and sacrificed. The times were stormy, and the Italian army was still tooning with insurrections and conspiracies, which were suppressed by a summation of the old system took place. Neither the nobility nor the body of the people became reconciled to the new system until years after, under the rule of Murat.

By a decree of June, 1808, Napoleon appointed 'Joseph Napoleon to be King of Spain and of the Indies,' and soon after Joseph Murat succeeded him as King of Naples. In Spain Joseph met with much greater difficulties than at Naples. He tried mildness and conciliation, but even these failed, owing to the stern unbending character of the people. During the five years of his Spanish reign, three times he was obliged by the successes of the allied armies to leave his capital; the last time (1810) to return no more. Joseph would have wished to be really and not nominally king of Spain, but this was prevented both by the people, who would not submit to him, and by his brother Napoleon, who appointed by degrees his own generals to be military governors in Spain, and they acted quite independently of King Joseph and his allies. In March, 1812, Joseph wrote to his brother, requesting to be allowed to reign his crown, as he saw that he could do no good in Spain. Soon after he repaired to Paris for the same purpose, and there his brother employed him in telling him that he expected to make peace with England, and then he should withdraw his armies from Spain. This was before the Russian expedition. General Foy, in his history of the Peninsular Wars, speaks of Joseph as follows:— "When he assumed the crown of Spain, Joseph was forty years of age. His figure was graceful, and his manners elegant. He was fond of women, of the fine arts, and of literature. His conversation was fluent and methodical, and was adorned with judicious reflections." After Napoleon's abdication (June, 1813), where he narrowly escaped being taken prisoner by the English, he withdrew to France. In January, 1814, when Napoleon set off for the army, he appointed Joseph lieutenant-general of the empire, and placed him at the head of the council of regency which was to assist the emperor. Napoleon wrote to him from Rheims on the 16th March, that in case the enemy should advance in irresistible force, he must send off towards the Loire the empress and his son, the Imperial court, the ministers, and all the heads of the administration. 'Do not leave my son for a moment,' added he; 'I should prefer hearing that he was at the bottom of the Seine rather than in the hands of the enemies of France.' Accordingly, when Rosenberg arrived before Paris on the 28th of the same month, Joseph sent off the empress and her son to Biar, after the battle of the 30th, in which the troops outside of Paris were driven in by the allies, Marmont told Joseph that he could no longer defend the capital, and Joseph authorised him to treat for a suspension of arms for a few hours in order to arrange the terms of a capitulation. (Thibaudet, Le Consulat et l'Empire, ix. 635.) Joseph then rejoined the empress at Biar. After Napoleon's abdication, Joseph and his brother Jerome thought of removing the empress and the regency to the south of France, but the empress refused, and was supported in her refusal by the members of the household. Soon after, the empress rejoined her father Francis of Austria, the regency was dissolved, and Joseph was set at liberty where he purchased the estate of Prangia, near Nyon, on the banks of the lake Leman. From thence he corresponded with his brother at Elba, and with Murat at Naples, who had been chosen Regent of the Empire by the Emperor of Austria for his grandson. He is said to have given Murat the advice of declaring against Austria in 1815, so as to make a diversion in favour of Napoleon, a diversion which proved of no use to Napoleon and was fatal to Murat. Napoleon having returned to Paris in March, 1816, Joseph rejoined the Imperial court, and was elected to the House of Peers. It is reported that, seeing the threatening appearance of the times, he advised Napoleon, before he set off for the army, to abdicate in favour of his son, and to appeal to his father's abdication, and to stand for the crown. 'This however was not done. After the return of Napoleon from his defeat at Waterloo and his second abdication..."
tion, Joseph embarked for the United States, after having a last interview with his brother at the ile d’Aix. He was well received in the United States, and after a time he fixed his residence on the banks of the Delaware, near Philadelphia, where he passed the winter. He changed the title of his house, de Survilliers, and lived in a style of affluence, affording employment to many of the labouring population, and hospitality to the French emigrants who resorted to America. His wife remained in Paris, and Frédéric settled in Brussels and afterwards at Florence. When the Paris revolution of 1830 became known in America, Joseph wrote a long letter or address to the House of Deputies, in which he put forth the claims of his nephew the young Napoleon. The letter was republished in the Chicago Journal of a story that England soon after, and resided some time in this country, and at last repaired to Italy, where he died at Florence, in July, 1844. He was buried in the vault of the church of Santa Croce. His name is said of the newspapers to have left a fortune of fifteen millions of francs.

(Biographical Sketch of Joseph Napoleon Bonaparte, London, 1833; Abel Hugo, Précis Historique des Événemens qui ont conduit Joseph Napoleon sur le Trône d’Espagne; Botti, Storia d’Italia; Compi, Anna di Vinc; Colletta, Storia del Regno di Napoli; Thibaudieu, Le Consulat et l’Empire.)

Bonaparte, Lucien, a younger brother of Napoleon, was born at Ajaccio in 1775. He emigrated to Malta with the rest of the family in 1793. He entered warmly into the revolutionary notions of that period, and made flaming speeches at various clubs, and wrote tracts pamphlets on liberty and equality. Soon after, he obtained employment in the French government in the south of France, wanted to remove to the prisons of Orange, where the guillotine was in constant activity. By showing a breach of the wants of the soldiers, and with informality in his commission, he detained the assumed victims under arrest at St. Maximin, until the fall of Robespierre put an end to the reign of terror. In the reaction which took place in the south of France against the so-called Jacobins, Lucien was arrested as such on account of his speeches, and one of those whom he had saved proved most hostile against him. He was however liberated after a time. In 1796 Lucien was appointed commissary at war, provost of the province of his native General Corps at Venice. In the following year he was elected deputy to the Council of the Five Hundred, and he went to reside at Paris, where he took a house, of which his sister, Elisa Baciocchi, was the honours. His drawing-room was resorted to by several of the most distinguished men of letters. He took the opposition side in the council, and allied himself to Sisylas and his party, who wished to try their hands at a new constitution. While Napoleon was in Egypt, Lucien wrote to him, complaining of the insolvency and misgovernment of the Executive Directory, and urging him to return to France, which letters are said to have been intercepted by the English cruisers. After Napoleon’s return, in October, 1799, Lucien, who was the president of the council, became the active leader of those who wished to overturn the Directory. In the stormy sitting of the 19th Brumaire, he resisted the motion made by several members to outlaw General Bonaparte, and as the confusion and uproar increased in the hall, he declared the council was increasing him, and they told them to march in and drive away the factious men who were sold to the English, the usual phrase in those times, and who were no longer the representatives of France. After the accomplishment of that revolution, in which he rendered most material assistance to his brother, he was raised to be a member of the commission which framed the new or Consular constitution. Soon after he was appointed minister of the interior, but remained in office only a short time, having had some quarrels with his brother upon matters of administra tion; and in October, 1800, after the campaign of Marengo, Napoleon sent him ambassador to Spain. His mission proved successful: he managed to ingratiate himself with the king, and, among other things, he succeeded in strengthening the French influence in Spain. He induced the weak Spanish government to join France in an attack upon Portugal, which ended by the latter country being obliged to sue for peace, for which it is paid dearly. He also completed the arrangements concerning the new kingdom of Etruria, to be given to the young infant, son of the Duke of Parma, who had married a Spanish princess, in exchange for which Spain ceded to France the island of Elba. The title of Duke of Parma and Lombardy to the title of Emperor of the French. To this last step the French court consented, and Napoleon’s vision of a united Italy, and also the institution of the Legion of Honour. Lucien was made a senator, and his brother gave him the senatorship or living of Sopeldorso, an estate of the former elector of Trelves. His wife being dead, Lucien married, in 1808, Mme. Sopelsdorf, a Portuguese lady, who was the daughter of the Duke of Braganza. Lucien disapproved of this marriage, as he had disapproved of the marriage of Jerome, because he looked forward to royal alliances for his brothers. Lucien himself, who was called the project of his life; but he says in his memoirs that he wished to have stopped there, and that he opposed from the first the idea of establishing an hereditary dynasty. When he saw his brother determined on assuming the imperial crown, he left France in the spring of 1804, and went to Italy, to Thibaudieu and others say that the two brothers quarrelled on other grounds: about Lucien’s marriage in particular. Lucien accuses Fouché of having, by his insidious reports, contributed to alienate his brother from his views. The Scandinavian war, and the hereditary succession in Napoleon’s family, named his brothers Joseph and Louis as eventual heirs to the throne, but made no mention of either Lucien or Jerome. Lucien, after a time, fixed his residence at Rome, but he was very friendly with his brothers, and became, as the Prince of Venice, and lived in a style of affluence. Being fond of literature and the fine arts, his house was much frequented. After the peace of Tilsit, Napoleon repaired to North Italy at the end of 1807, and sent for his brother Lucien to join him at Mantua. The two brothers had there a conference, in which it seems that Napoleon offered to give Lucien a kingdom in Italy, at the same time telling him plainly that in such case his brother would have to deliver up his empire to the internal as well as the external policy of his administration. Lucien declined accepting a crown on those terms, and said that he preferred to remain in a private station. ‘Be it so,’ Napoleon replied; ‘you cannot have henceforth any grounds of complaint against me.’ But he added in parting, that Lucien would not fall in with his system of politics, he must prepare to quit the Continent, where his silent opposition could no longer be tolerated. (Rapport de Lucien Bonaparte, Our Memorias de Lucien Bonaparte, Secret de Sa Majesté.)

Lucien returned to Rome, where he purchased the estate of Canino, in the province of Viterbo, near the borders of Tuscany. Pope Pius VII. created him Prince of Canino and Musignano in 1808. Soon after Napoleon began a course of persecution against the Roman Catholics. Lucien, who was in the arrest of the pope, and the seizure of his domains. When the French took possession of Rome in 1809, Lucien, who had expressed himself very freely against this part of his brother’s measures, was confined in the Caffarelli, and restored to his country estate. In 1810 he resolved to go to the United States, and having obtained passports from his brother, some say without any passports, he sailed from Civitavecchia, but was seized by an English cruiser and carried to Malta, where after a time he obtained permission from the British government to reside in England under surveillance. Ludlow castle was fixed upon as his residence. Some time after, he removed to a place in the neighbourhood, where he remained till the end of his days. His son, the last of the Bonaparte family, is the subject of a poem of Charlemagne. After the peace of 1814 he returned to Rome, where he dedicated to Pope Pius his poem of Charlemagne. When Napoleon returned to France from Elba, in 1815, Lucien repaired to Paris. His object in this does not appear very clear. He has been suspected of having received a generous impulse, to tender to his brother his advice in the hour of danger, and to keep him also, if possible, within constitutional limits. However this may be, he went to live at the seat of the Caffarelli family, and is the subject of an imperial prince, and claimed a seat of honour as much as in the new House of Peers. This was resisted by several peers, on the ground that he had never been acknowledged as a prince by the title of Caffarelli, nor was he entitled to receive a pension such. He then took his seat in the body of the house in company with the private councils that took place, he advised Napoleon to offer to the Emperor of Austria, in order to detach him from
The allies, to abdicate in favour of his son. This manoeuvre
not having succeeded, Napoleon set off for the army, lost the
battle, and himself, as well as his brother Joseph, was taken
by Lucien being appointed extraordinary commissioner of
the emperor, to communicate with the representatives of the
people, to revive in the Chamber of Deputies a feeling of
national devotion which it was right to shorten. In this
match, Lucien obtained the gratitude of the nation, but was
an answered sternly by La Fayette. 'The nation has followed your brother over fifty
fields of battle, from the burning sands of Egypt to the frozen
dezert of Africa. The army, as he feels it to be for this that we mourn the loss of three millions of Frenchmen!' Lucien advised his brother to dissolve
the Chambers, since he could not manage them, and to assume
the dictatorship. Napoleon hesitated, and at last refused; he
said he was not Paris and its brilliant glory. Lucien had
ever seen what Lucien did not see, that the attempt would only
lead to a short protracted struggle, attended by additional calami-
ties to France and to himself. Lucien says that he was opposed
to Napoleon's abdication, but when he saw his brother determined upon it, he assisted upon its being made
at least in favour of young Napoleon. Napoleon smiled and
shook his head incredulously, but at length inserted the
clausule in favour of his son. Lucien then proceeded to address
the Senate, and Napoleon repaired
Il, but in vain he cried out, according to the forms of
the old monarchy. 'The emperor has abdicated, long live
the emperor!' The House remained mute, and as he went on speaking in confusion. He represented himself with being an alien, a foreign titulary, a Roman prince,
and not even a citizen of France. Soon after the ill-disposed
armies made their appearance, Napoleon went to Rochefort, and Lucien set out to return to Italy. He rejoined his wife at Rome, where he afterwards spent many years in peaceful retirement.
In 1828 he began digging at a place called La Cucumella on his estate of Canino, which is believed to have been the site of the ancient Vetulonia, once an important Etruscan city, and he gathered an ample collection of Etruscan antiquities, of which he published a description: 'Museums Etrusci de Lucien Bonaparte, Prince de Canino.' During the insurrection in the Papal States, in 1831, Lucien kept himself and his family aloof from all trouble. When he returned from
his visit to England, where he published several of his works. He returned to Italy, where he died in 1840. His eldest son, Charles Lucien Bonaparte, well known as a naturalist, and
author of the 'Ornithology of the United States,' and of the
'Iconography della Fauna Italiana,' succeeded to the title. Enthusiastic in the cause of science, he has been the chief
promoter of the annual congresses of the scientific men of
Italy. Of Lucien's other children, one, having had some
affairs to attend to, it is reported that she had gone to Naples,
Italy. Lucien ranks as a French author in prose and in verse. His published works are:--1. 'Charlemagne, ou l'Eglise délivrée,' an epic poem in 24 cantos, which has been translated into English by S. Butler; 2. 'La Rev. F. Haremarte,' 1 vol.; 3. 'La Corse sauve,' a poem in 12 cantos. 3. 'Mémoires de Lucien Bonaparte, Prince de Canino, écrits par lui-même.' 8vo, London, 1836. 4. 'Réponses de Lucien Bonaparte aux Mémoires du Général Lamarque,' London, 1835. In
his public political confession, and at the same time an apology for his own
and Napoleon's political conduct during the hundred dias;
it contains some curious revelations and frank avowals, though
it is rather inconsistent in its reasoning, like all the attempted
justifications of Napoleon's political morality. Several of
Lucien's speeches while a tribune have also been published;
and among others his 'Rapport sur l'Organisation des Cultes,' and
'Discours sur la Légion d'Honneur.' A defamatory book, en-
titling, in which his father lost his life, and his mother was
imprisoned and was only saved by the timely death of Robes-
pierre. After the end of the reign of terror, Hertense
was intrusted to Madame Canpan for her education. Her
mother's second marriage with General Bonaparte bright-
ened her prospects; and when her stepfather became First
P. C. S., No. 28.

Consul, Hertense went to enliven by her youthful grace
and sprightly humour the court circle of the Tulieres. Napoleon,
who was much pleased with her, as well as with his
brother Eugene, and he behaved as a real father to both.
In 1802 he gave Hertense in marriage to his younger brother
Louis. It seems that his other brothers were not favourable
towards this marriage; but Hertense had a son by him,
who lived for many years after his father's death.
In 1804, Hertense's relations with the Tuileries were as
friendly as before, and she succeeded to her father's
title of Countess of Harcourt, a title which he had
inherited from his mother Anne de Mercy. She
marriage with the hereditary prince of Baden.
In the same year Louis was appointed King of Holland,
and his wife followed him thither, not without regretting
her做不到. In Holland she was by no means able to favour his new subjects, the Dutch and their interests, but her
husband was all for France and for Napoleon, who expected
that his brothers should act merely as his lieutenants in the
countries over which he appointed them to rule. After the
death of her eldest son in 1807, Hertense was advised
to travel for her health, and she ultimately returned to Paris,
where she was delivered of a third son. In 1809, when Louis and Napoleon were at variance about Dutch politics,
when a corps of Poles was sent to Piacenza to enforce
her husband and keep him within the bounds of his allegiance
to his imperial brother. Louis however proved refractory,
and at last quitted Holland, of which Napoleon took possession.
He restored a brother to his wife, and was received in Paris,
where she had an hotel and a princely household, and went
by the name of the Queen of Holland, though her husband
was no longer king. The eldest of her two living sons,
was anIFICATION.
This son, in whom her mother lighted the prospects of Hertense and her children,
but she bore this disappointment with equanimity, always
professing the most unbounded devotion to Napoleon, and
obedience to his will. She became separated though not
divorced from her husband, whose temper and taste did not
agree with her own. In 1814 she remained at Paris and
was zealous in urging the defence of the town against the
allies. When Napoleon abdicated at Fontainebleau, she re-
signed herself and her children to the care of the King of
France; and in the return of Elba, which however has been denied by her
friends. Meanwhile her husband was in the French Courts to
have his two sons removed from her charge and restored to
him, but the return of Napoleon put a stop to the pro-
\nHurtense. She married Joseph Bonaparte's second daughter.
In 1831 both her sons, much to her annoyance, joined the
insurrection in the Papal States. The eldest fell ill during that short cam-
bination, and died at Amandola. The youngest, who was in
Italy by the anxious mother, and after some narrow escapes
they returned together to Arenenberg. This remaining son,
Charles Louis, was naturalized as a citizen of the canton
of Thurgau. In 1832 he married a sister of Thurgau.
In 1837 he married a young woman of fifteen, and himself at the head of a military insurrection at Sittard, he
was arrested, but Louis-Philippe interfered to save him
from punishment on condition of his emigrating to America.
Hertense was too ill to follow him, and she died at Arenen-
berg, in October, 1837. Her son had returned from America
to attend her last moments. Her remains were taken
Vol. I. 2 F
to France, and buried in the church of Ruel near Paris, by the side of three of her mother Josephine. Her son being afterwards expelled from Switzerland, in consequence of the remonstrances of the French government, came to England, from whence he made another insurrectionary attempt in 1839, for which he was confined in the castle of Ham, where he still remains. Hortense had been deprived of the duchy of St. Leu at the second restoration of the Bourbons. She published some reminiscences or fragments of her life, entitled her Mémoires, or "La Reine Hortense en Italie, en France, et en Angleterre, pendant l'année 1831," Svo. Paris, 1834. Amiable, kind-hearted, and womanly in her feelings and tastes, she is out of her sphere when talking of grave political questions, and administration of state affairs. It was a matter of impulse rather than of reason. Hortense was fond of music, and she composed several airs which have been applauded, among others a favourite one, "Partant pour la Syrie,—le jeune et beau Donos." (La Reine Hortense en Italie already quoted; Supplement to the Biographie Universelle, art. 'Hortense'; Thilaudeau, Le Consulat et l'Empire; Romances mises en musique par Hortense Duchesse de St. Leu, with a biographical notice, by Cowles.)

BONE, HENRY, R. A., the most distinguished enamel painter of his time, carried this branch of painting to a degree of perfection which his predecessors had not even approached. He was the son of a cabinet chair-maker at Truro, in Cornwall, where he was born in 1755. He showed at an early age some artistic ability, and was accordingly sent to learn the china business. He married one Cockworth, who, in 1778, at the expiration of Bone's term of apprenticeship, was settled in Bristol. He remained in the employ of Mr. Cockworth for another year, at the expiration of which the china business failed, and Bone ventured to try his fortune in London. For many years he chiefly employed in London by jewellers and others in enamel-painting for watch-cases, brooches, lockets, and the like; and also in a species of art called device-painting. He had, however, also the honor of being an enamet portrait of his wife, which he exhibited at the Royal Academy in 1780, and by an original picture of a Muse and Cupid, which, though only five inches and a quarter by four inches and a quarter, was at that time considered to be of extraordinary dimensions: it was engraved in 1790 by R. Dagle.

Towards the close of the last century his engagements increased to that extent, that he was enabled to decline the drudgery of his profession, and to confine himself to miniature and portrait painting, and he executed his own enamels and his own miniatures. In 1800 his reputation was established by the appointment of enamel painter to the Prince of Wales, a distinction which was succeeded in the following year by his election to the Royal Academy. In 1806, he was appointed to supply pictures, and in 1807 he became the first official artist to the British government, for which service he was granted a pension of forty pounds a year. He was also appointed to supply portraits of the royal family, and was expressly commissioned to execute for the Prince Regent some engravings of his first experiments in the art, which was the beginning of his reputation as a portrait painter. He was also commissioned to execute portraits of the King and Queen, and was subsequently appointed painter to George III., George IV., and William IV. He was elected a full Academician in 1811, and for twenty years from this time he was assiduously employed in producing a long succession of admirable works, most of them of unprecedented dimensions; but about 1831 his advanced years compelled him to cease his professional labours, and he left his house in Berners Street, where he had chiefly resided, and retired to Clarendon Square, Soho's Town, where he resided during the autumn of 1831. In December, 1832, he was in full employment for many years, his family was too numerous to allow him to grow rich. He had a son in the army and another in the navy, both of whom he survived: the former, Lieutenant Bone, died in consequence of wounds received at the battle of Toulouse. H. P. Bone, the present enamel painter to the queen, is also one of his sons. Mrs. Bone, whom he married in 1779, was a Miss Vandermeulen, and was directly descended from Peter, the brother of the celebrated Charles Anthony Vandermeulen, and himself battle-painter to William III.

The following are Bone's principal works:—The Death of Dido; Cynon and Iphigenia; Venus; and Hope nursing Love, after Sir Joshua Reynolds; a copy (in the style of the original) of Miss Bellini's portrait of Henry VIII. for his son, H. P. Bone, up of a picture of Beecheus and Ariadne, by Titian, eighteen inches by sixteen and a half, dimensions up to this time unapproached except by himself, which was purchased by George Bowles, Esq., of Cresw. Bab. Square, for 2000 guineas. The original picture, which is now in the National Gallery, was then the property of the late Lord Kinnaid, who lent it to Bone for the express purpose of copying it. A Venus recumbent, after Titian; Bathsheba, after N. Poussan; La Belle Vierge, after Raphael; and an Assumption of the Virgin, after Murillo. A series of portraits of the Rosell family, from the reign of Henry VII., to the present time, executed for the late Duke of Bedford, and now at Woburn Abbey. A set of portraits of the principal Royalties distingushed during the civil war of Charles I., for J. P. Ord, Esq., of Donnington, Chelsea, who unfortunately died the day after the portrait was completed. A portrait of Mr. H. P. Bone, who, in all the great works, was his father's assistant. And, finally, his greatest and most interesting work, a series of eight-five portraits of distinguished persons in the business of art, according to the plan of C. A. van Dyck, ranging from five inches by four to thirteen inches by eight: it remained in the possession of the artist during his life, but it was his desire that after his decease it should be offered to the government for purchase, which was accordingly done; but although at the moderate price of 5000l., the British government declined the purchase. The sum was considered too much for a collection comprising eighty-five authentic portraits of the most distinguished characters of one of the most interesting periods of English history. The fact of their being copies does not render them less interesting or less instructive to the public. They were disposed of by public sale, and the greater part of them were purchased, either at the sale or since, by W. J. Banks, Esq.

(Annual Biography and Obituary, 1856.)

BONINGTON, RICHARD PARNES, was born in the village of Arnold, near Nottingham, in 1801. Bonington's father was a landscape and portrait painter, and perceiving a strong tendency in his son to that branch of art, he gave him opportunities to study art. At an early age, he trained him from his childhood in such a manner as in his judgment was best calculated to fit him for his future profession, at the same time not neglecting his education, as frequently happens, in those branches of instruction most necessary to him; for the fact of his being copies does not render them less interesting or less instructive to the public. They were disposed of by public sale, and the greater part of them were purchased, either at the sale or since, by W. J. Banks, Esq.

Having obtained a considerable reputation in Paris by his works, which were chiefly marine and coast views, he visited Italy, where Venice, 'throne of her hundred isles,' offered him a rich field for study; and Bonington, with his usual precocity and genius for painting, so soon as he had become conversant with the art, undertook the making of a series of pictures, which he had already prepared the sketches for, but he was already the victim of a fatal disease; he was in a deep decline, and the nervous debility inherent in this complaint reduced him to such a low state, that his constitution sunk under the excitement of his very success when he returned to England. He died in London, shortly after his return from a second visit to Paris, in September 1828, having not quite finished his twenty-sixth year. He painted chiefly in water-colours, and mostly marine or river views; his style is simple and picturesque, quite free from conventionalisms.

Sir Thomas Lawrence, who attended Bonington's funeral, speaks of him in the following terms:—"A talent to a great degree, shortly after his death,—Your pupil has been so fatally verified! The last duties have just been paid to the lamented Mr. Bonington. Except in the case of Mr. Harlowe, I have never known, in my own time, the early death of a youth to excite more universal regret and so rapid a decline. If I may judge from the later direction of his studies, and from recollections of a memorable conversation, his mind seemed expanding in every way, and ripening into full manhood, and I dare not conceive he could have carried his ambition which makes confinement to lesser departments in the art painfully irksome and annoying:—"

But the fair guardian when we come to find,
Comes the blind Fury with the abhorred shaven,
And takes the thin open eye.
BOO

A series of twenty-four engravings from the works of Bonington has been published by Mr. Carpenter. (Cunningham, Lives of British Painters, &c.)

BONOMI, JOSEPH, an Italian architect who practised at Forlì, died January 31, 1755. He was born at Forlì, in the parapeted province of the same name, in the year 1664, and was the son of a barber. He first appeared in public life in 1685, when he published a treatise on the art of architecture under the name of Toodool. In 1697 he was invited to England by the brothers Adam, and was for many years employed by them as an assistant and architectural draftsman. The fruits of his labours in this respect are known to all in the form of drawings and sketches. In 1725, however, he returned to Italy, and was engaged in the design and execution of the celebrated church of San Zaccaria, near Venice, which was begun in 1711 and finished in 1716. In 1727 he published a treatise on the art of architecture under the name of "Bauzeitung," in which he gave a complete description of the plans and elevations of the buildings he had designed and executed. In 1744 he was elected an Associate of the Royal Academy, and was never raised to the rank of a full member. He died at Forlì in 1755, and was buried in the parapeted church of San Zaccaria, where a monument bears his effigy.

Bonomi's chief professional works are, additions and alterations at Langley Hall, Kent, 1790; the chapel of the Spanish nuns, 1796; the Eastern House, Kent, for G. F. Hatton, Esq., father of the present Earl of Winchester, 1783; the pyramidal mausoleum in Buckingh-arn Park, Norfolk, 1783; Longford Hall, Salop; mansion at Laverstock, Hants, for H. Portal, Esq., 1787; the splendid mausoleum of a lady in the park of Buckingham House, 1788; the Royal Library, Argyle, 1803, which last (not yet completed) is his most celebrated work, and is given as an example of modern design in the treatise on Civil Architecture (by Telford) in Brewer's Encyclopedia, although chiefly remarkable for the heresy, if not the selectism, of an entrance portico with a column in the centre. The reason assigned for this caprice is, that the portico was intended for carriages to drive through, it was thought a column in the centre of the front would express its purpose more truly ; and a column, taken by itself, a column in that situation is not a little objectionable, on account of its obstructing the view from the entrance door. Nevertheless the design is praised as "displaying originality of genius."

Bonomi also made designs for the new sacristy of St. Peter's at Rome, of which editions be bad been appointed honorary architect in 1804.

BOOKBINDING, or BUONSIGNORE, FER-

DINO, author of the "King of Sardinia, and professor of architecture at Turin," is entitled to honourable distinction in his profession. Although known to us only by one work, yet that alone sufficiently proclaims his talent and establishes his claim to immortal immortality. The title of his book, "Un Pezzo di Terra, in Turin, the ex-soto structure intended to commemorate the king's return to his dominions, is one of the most classical and tasteful specimens of recent Italian architecture; a happy application of the idea of the Pantheon at Rome on a moderate scale; but by no means a servile imitation of it—certainly is distinguished from it by being raised on a spreading-out basement about 16 feet high and 12 feet in diameter, which, following the plan of the rotunda, forms a concave or pointed arch, and forms a dome, which is effectually raised on the cupola, is divided on its plan into eight compartments alternately closed and open, the latter forming four semicircular recesses or trumens, with two Corinthian columns in each, and four circular divisions, with four large pannels with bas-reliefs in the attic above the order. The dome is richly coffered with octagonal caissons. Plans, &c., of this highly interesting structure may be found in the volume of the "Bauzeitung" for 1857.

BOOKBINDING is, in fact, merely groups of leaves, either of thin skin or of some kind of vegetable mem- brane, the art of the bookbinder was a very primitive one. He had simply to paste or glue the leaves together, so as to form an extended sheet, and to attach it to a cylinder round which it might be rolled. Even to the present day it is customary in some Oriental countries to write on slips of paper stuck together to form long sheets of paper, and then to roll these up, and to attach this to rollers at each end, clasped with gold or silver. The square form of binding, now so well known, was of later date, and constituted a vast stride in the art. It was adopted first by the Christians, and was next adopted by the Jews, in misused in Catholic countries, long before the invention of printing, and has been retained as the most convenient mode of binding.

In the binding of a book at the present day, whether done by machine or by hand, there are generally three classes or successive stages of operations, varying in detail according to circumstances, but following each other pretty much in regular order. These relate first to the grouping of the sheets to- gether, in a uniform and symmetrical way; next to the fin- ishing of the stiff covers or boards which give firmness to the book; and lastly to those processes which relate rather to the external beauty than to the strength or efficiency of the book. These we shall designate as—1. Preparing; 2. Binding; 3. Finishing; and shall notice the different kinds as we go on.

1. Preparing. A book is built up of several sheets, each one folded and re-folded so as to assume a more convenient shape. The number of these sections, called folds, or sections, foldings depends on the size of the work; thus octavo or 8vo. implies that there are eight printed pages on one side of a sheet, and that the sheet must be so folded as to be brought to one-eighth of its original size. The number whereby the sheets are designated is called the "number of pages," and is the number of printed pages obtained from one side of a printed sheet, such as folio, 4to., 8vo., 12mo., 16mo., 18mo., 24mo., 32mo., &c. Some of the sheets employed are larger than others; thus 'royal octavo,' though folded into the same number of pages as 'octavo,' is larger in size, through the sheet of paper being larger.

The folding of the printed sheets is one of the first oper- ations in preparing for the binder. Each sheet has a letter at the bottom, such as A, B, C, D, E, F, &c., usually in accordance with the numbers of the signatures, which are thus, as many signatures as there are sheets to form the volume. When the alphabet is in this way exhausted, another in smaller type, or duplicate letters, or letters combined with numerals, are employed. There is a heap of signature a, another heap of signature b, and so on. The folder sits before a bench, on which each sheet is spread out in succession; and the folding is aided by the use of a bone or ivory folding-knife: it is done with great rapidity, and with satisfactory accuracy which rarely results in error.

The folded sheets are 'gathered' into new groups, fitted to make up into books; that is, each new group is made to contain one copy of the sheet bearing signature a, another of b, another of c, &c. The groups are next 'collated,' that is, examined throughout to see that no mistake in the order of arrangement occurs.

If the sheets thus folded, gathered, and collated, are to be put into 'boards,' they are sewn in the next process; but if they are to be bound, and therefore finished in a more careful manner, they are beaten or pressed before being sewn, as a means of bringing them to a more compact and smooth state. Until recent periods this process used to be effected by means of the hammer; the volume being divided into parcels of a few sheets; and these parcels, held flat on a smooth stone, being beaten with a heavy hammer. But the 'rolling-press' has greatly improved the mode of proceeding. This press consists of two or more rollers, being set on a common shaft; the parcels of a volume are placed between the plates and then passed between the rollers, which gives them a more effective and eductive pressure than the hammer. Sometimes the ink becomes 'transferred' to the opposite page by this process, which is not properly conducted, to the great dis- figurement of the book.

In sewing together the sheets for a volume, they are not actually fastened one to another, but all are in common at- tached to a range of parallel straps or bands placed about the back of the volume. Sometimes marks are cut with a saw across the back edges of the sheets, to receive the strings; but in others cases this is dispensed with. The process of sewing is carried on by the aid of a sewing-press, which consists of a bed or boards, and by a needle of from 9 to 11 inches long, and a cross-bar at the top. The strings are fastened to this cross-bar and are stretched vertically downwards to the bod.
of the press, where they are firmly secured. The number of these strings depends principally on the size of the book, and varies from two to eight or ten. The sewers (a female) sits in front of the press, with a folded sheet of paper on it, with the back edge in contact with the strings, opens the sheet in the middle, and sews it to the strings, passing a needle and thread to and fro. The needle passes through the back edge of the sheet twice, and the thread, being taken out of the eye of the needle, is twisted around every string, and thus connect them and the sheet together. This being done with respect to the first sheet, a second is laid on the first, and sewn in a similar manner; and so on until the whole is done in the same way, they are then to form the volume—all the threads being fastened to all the strings, and, indirectly, to each other; for the threads pass from one sheet to another by a peculiar kind of stitch called a ‘kitch’ stitch.

The boards are by the sewing-process brought together into a book-like form, and are then ready to pass through the operations connected with the boards and covers. The back-edges of the sheets are glued together, to increase the strength of the volume; this is done simply holding the book in the left hand, and brushing on it a little warm melted glue. This being dried, the ends of the strings (which are allowed to hang loose for an inch or so beyond the volume) are scraped thin, for the sake either of being rendered less apparent, or for the strings to be more easily to allow of fastening on the boards. The volume is next rounded in a singular manner; that is, rendered convex on the back and concave or hollow on the fore-edge. The workman lays the volume on the board so as to make the back hand, with the left draws the sheets in such a way as to produce the rounding of the edges: the manipulation is a curious one; and as the glue is not yet quite dry, the sheets are enabled to yield a little to the action of the hand and hammer.

A groove is now made to receive the boards or stiff covers. These boards would project beyond the width of the back edge, and would be both unsightly and inconvenient, if some means were not adopted for compressing or confining them. A thin bevel-edged board is placed on each side of the volume far enough from the back edge to allow of a kind of ledge to be formed; these ‘back-boards,’ as they are called, are placed parallel with the back edge; and the volume, with these boards on either side, is lowered into the press, the back edge uppermost. By hammering this edge in a particular way, it is made to expand or spread out, and thus to form two ledges against which the covers of the book are to be placed. Although in common language we call the covers of a book the stiff sides which keep it firm and compact, yet the terms applied by a bookbinder are rather different. With him, this stiff envelope is called the board, the leather or cloth applied outside the board is the cover, and the two togethér form the case; and it will be convenient to retain the same terms here.

If the book is to be boarded, to use a familiar term, the edges of the leaves are not often cut; but if it is to be bound, this cutting of the edges is an essential process, and is done before the boards are fitted into the volume, which is thus effected. The volume, placed between two boards, is screwed in a press; one of the ends of the volume being left projecting a little above the press. A cutting instrument, called a ‘plough,’ partaking in some degree of the action of a carpenter’s plane, is passed over the end of the volume so as to shave off the ragged edges of the sheets, and leave them perfectly smooth. The volume is reversed in position, and the same thing done with the other end. It is then taken out of the press, and the edges are perfectly straight, so as to show the convexity of the back and the concavity of the front edge alike to a plane level, which admits of the front edges of the leaves being cut in the same manner as the top and bottom edges. These same operations are then repeated on being released from the press; and then presents the neat appearance which a concave front edge, convex back, and plane top and bottom edges, are calculated to give.

Bound books are made only for applying ‘to boards,’ boards made of ‘millboard,’ or smooth brown or drab-coloured pasteboard made of several layers of paper glued together and strongly pressed. The sizes and thicknesses vary according to the size of the volume and the kind of binding for which they are to be used. The boards are cut very quickly from the large sheets by a cutting edge applied nearly in the same way as in tobacco-shredding or in chaff-cutting. In attaching these boards to the book, the strength of the fastening depends on the kind of binding. If the book is to be bound, holes are made through the boards, opposite to the strings, and the loose ends of the strings, being passed through these holes, are glued down firmly to the inner surface of the back, thus rendering the book stiff and firm. On the other hand, the volume is to be in ‘cloth boards,’ the strings are not generally passed through and glued down in this way, but the boards are fastened to the book chiefly by being passed over the outer edge, and the volume is placed between the outer edge and the back of the book. These boards, in this latter case, are brought somewhat to a finished state before being attached to the volume; for the cloth is cut to the required size, and basted or sewed to the volume; and, as may be seen, they are placed sufficiently wide apart to allow for the thickness of the book. Some books, especially in the present day, are made ‘hollow in the back;’ which is thus produced,—A double layer of paper or of cloth is placed between the leather of the back and the outer edge of the boards; the latter is glued on to the outer edge, and the back edge of the sheets to the inner layer, and as the two layers are connected at their edges, but detached or loose from each other at their surfaces, they give a kind of hollowness to the back of the books.

Most well-bound books have a little appendage at the top of the back-edge, called the ‘head-band.’ This gives a neat finish to the book, and at the same time strengthens the leather covering of the back-edge at that part. For common books, the head-bands, as they are called, are made of a double thickness of paper, which is first pasted or sewed to the back of the book, and then cut off; for better work it consists of a little strip of vellum or paste-board, around which coloured silk threads are twisted by the same process which fastens it to the volume.

When the book is sewn with a single uniform colour, the cloth cover is applied to the boards before the latter are attached to the volume; but when it is ‘whole bound,’ having leather all over the outer surface, or ‘half-bound,’ having partly leather and partly paper at the surface, these coverings are put on after the boards are attached to the book. The leather in the case of a whole bound is cut to a size rather larger than is required to allow for turning and turning in, and is laid down sideways on a smooth board. The back of the leather is well pasted, and the book placed down upon it, the bands of the workman being, and adjusting, and pressing the leather, until it adheres closely to the book in every part. If ‘half-binding’ is the style of work, then the leather is so cut as to cover the back and a small portion of the front board or side; while four small pieces are applied to the corners. The paper is subsequently so pasted on as to hide the ragged edges of all these pieces of leather.

**Finishing.**—By the processes above described, the book has received all which is really necessary for service; the sheets have been arranged in proper order, sewed to rings, fastened to boards, and covered with cloth, leather, or paper.

But a large portion of the talent, the ingenuity, and the capital applied to this branch of manufacture depend on the subse- quent processes, which determine the kind which the book is subjected. These must be rapidly glanced at.

First, with respect to the edges. Most persons who purchase books are aware that, if in ‘boards’ or ‘cloth-boards,’ the top edges of the sheets, although placed level, are often slightly bevelled, so that they do not when the book is standing upright, lie exactly level, an appearance which is very unct. In some cases, to make a nearer approach towards neatness, the fore-edge only is cut; in occasional instances, too, the whole of the edges are cut, but left white. But a white edge to a book would soon become discoloured and unsightly; and it is far more usual either to scrape the edge with colour or to gild it. In sprinkling, the edges of several books are laid even one with another, and a piece of sponge, dipped into liquid colour, is passed lightly over the edges, so as to give them the required tint; or the paste is used, a more general method is that of sprinkling. The books are in this case ranged side by side on a bench, and a brush dipped in the liquid colour (which is formed of some such pigments as are generally used in paper-making) is passed lightly over the books, and lightly tapped against a stick, whereby a shower of spots fall on the edges of the books, producing an appearance depending on the colour employed, and the manner in which the shower is performed. These spots are sometimes produced, by a peculiar admixture and management of different colours sprinkled on the edge of the book.
a piece of steel, and is coated with a mixture of red chalk and water. The gold is blown out from small books, and spread on a leather cushion, where it is cut to the proper size by a saw. Then, as the gold is laid upon a table, a layer of white of egg mixed with water, and with this the partially dry edge of the book is moistened; the gold is then taken up on a flat kind of brush, and applied to the moistened edge, to which it adheres. When all the three edges have been gilt in this way, and left to remain for a very few minutes, the workman takes a burnisher formed of a very smooth piece of hard stone, and setting the end of his thumb against the shoulder, rubs the gold very forcibly—not (as might be supposed) to press, but rather that with the required degree of polish, by rubbing down the minute asperities which may be occasioned by the paper beneath. The gold employed has a greater or less degree of solidity according to the cost of the book.

From the edges we pass to the covers; and first, to leather covers. The leather so employed is 'roan' or sheep, 'sarf,' 'Morocco,' and 'Russia'; at least, these are the principal kinds, to which alone we need allusion here. These kinds of leather receive their colour at the dye-houses in Bermondsey, where, they are prepared; but 'roan'-bound books, such as school-books, are often sprinkled with colour by the bookbinders after the leather has been attached to the boards. For this operation an instrument of the form of a broad bar is used in a manner such that the leaves may hang vertically downwards, while the boards lie horizontal. A brush is dipped into the liquid colour, and dashed or sprinkled on the cover so as to give a group of spots or wavy lines, at the taste of the workman, or to suit the taste of the client. The surface of the boards is then beaten down; which, of course, occasions the formation of a new surface from the bookbinder; but Morocco is sometimes treated in the following manner—The Morocco leather employed for chair-covers and such purposes is made either of kid-skin or sheep-skin according to its quality, and has a wrinkled appearance, arising from the surface having been rubbed very hard with a minutely grooved piece of wood. Now for many purposes of bookbinding these wrinkles cannot be removed, and are, therefore, in many cases, used as an ornament, which may be formed into any required shape. Two pieces of leather being well flattened, and laid face to face, the upper one is rubbed in different directions with a flat piece of cork, by which the wrinkles are removed, and a slightly granulated texture produced.

The decorations produced on a leather-bound book by heated stamps or dies are very diversified. The dies for producing any particular device are fixed to handles, and when about to be used are warmed in a gas-heated stove. Many such dies are often used for one book, and the process of producing a sunken ornamental device by using these tools by hand is called 'blind-stamping.' But for many purposes it is more convenient to fasten a great number of small dies as partial devices to a metallic plate, by means of glue and clout, and then to stamp the required form on the flat plate by means of a press: this is called 'blocking.'

All the devices so produced on a book are called 'blind,' if no gold is employed; but much of the beauty of the workmanship and decoration consists in the rendering of this forming part of all the pattern. The leather, as laid on the book, is not in a fit state for receiving the gold without some modification of surface. It first receives a coating of parchment-silk; then two or three coatings of white of egg, whereby a slight glossiness is produced; and just before the gold is to be laid on, the surface is slightly moistened with oil. The gold, cut up into small pieces to suit the kind of ornament, is laid on the book with a flat camel-hair brush; and then, when the whole is dry, is pressed upon the gold, whereby two effects are produced at once—the production of the device, and the fixing of the gold to the leather. A piece of soft rag, lightly passed over the book, removes the small superfluous fragments of gold, and leaves the gilt device clearly marked.

But the decoration of volumes bound in cloth, although occupying a far lower level in respect to manual dexterity than the more costly binding in leather, has occupied much labour. The method was to starch the cloth, and then, using as a means for diffusing neat and even elegant volumes at a marvellously low price. Cloth-binding, in fact, has been the key of one great advance in the art—the application of machinery to book-binding processes with a similar economy. The cloth which books are covered is generally cotton of a particular kind, woven for the purpose. When the system of cloth-binding came up, about twenty years ago, the cloth was used in the unskirted state, with the warp and weft threads visibly crossing each other at right angles. But now the cloth is more generally so altered by an artificial embossment of surface, as to leave the threads barely visible, and to give to the paper a remarkable resemblance to the appearance of leather; a resemblance which, in some cases, the beholder has rarely received, may, indeed, have deceived many an eye a few years ago. This embossing is produced by drawing the cloth, while yet uncut for the purposes of binding, between two steel rollers, of which the concavity and convexity are employed respectively, so as to give a row of gas-jets through their hollow centre, so as to keep up a constant temperature. There must be as many pairs of rollers as there are different devices for embossing each book; so that the number of large factories is very considerable. Some of the rollers are intended for the production of a uniform device over the whole surface of the cloth; while others have particular devices for each particular book, and are consequently planned with especial reference to the size of the volume. The rapidity with which books can be now bound in this way, is one great cause of the surprising cheapness at which they are often sold. Five or six years ago, Dr. Ure said that 'should Mesers. Westleys (one of the largest book dealers) bind this list of volumes, on any given occasion, they can have them all ready for publication within the incredibly short period of two days;' and this has been more than borne out by what has since been done.

Other kinds of cloth-covers, especially those which are much decorated with gold, are stamped with the device after being pasted on the covers, instead of before; they are, in fact, cases, each one quite ready to affix to the book in a speedy manner after being stamped. Great pressure is required in this process, for the mill-board is required to yield to the force, as well as the cloth itself. The case is placed down flat on an iron bed heated with gas from beneath; above is a press, to the lower end of which is attached the stamping-die or block, face to face. Great mechanical power is then brought to bear on it, and the press descends with force sufficient to impart the pattern to the cover, gilt or not, according to the circumstances of the case.

India-rubber Binding.—The last few years have witnessed the introduction of a singular mode of binding, arising out of the use of a cement or glue of caoutchouc, instead of sewing, for fastening the sheets of books together. In this process, the sheets are not allowed to retain the folded form customary in other kinds of binding; but the edges are cut all four sides—on the back as well as the front, top, and bottom; the consequence of which is, that all the leaves are separated one from another. The group of leaves to form one volume is placed in a kind of cylindrical case, formed of india-rubber, to which the back-edge and concavity to the front; and a cement of caoutchouc is carefully applied to the back-edge, whereby all the leaves become cemented together. The subsequent operations are not very different as compared with other methods, a certain kind of flexibility resulting from this method, advantageous when the volume is thick. This method was introduced by Mr. Hancock, and in reference to it Dr. Ure remarks:—"For engravings, atlases, and ledgers, this binding is admirably adapted, because it can be displayed most freely, without the risk of dislocating the volume; but for security, three or four stitches should be made. The leaves of music-books bound with caoutchouc, are often turned over at their sides and do not fail; the sheets, and do not torment the musician like the leaves of the ordinary books, which are so ready to spring back again. Manuscripts and collections of letters which happen to have little or no margin left at the back for stitching them by, may be bound by Mr. Hancock's plan without the least encroachment upon the writing. The thickest ledgers thus bound open as easily as paper in quire, and may be written up to the innermost margin of the book without the least inconvenience." The operation consists of cementing the leaves or sheets together at the back, with a composition of isinglass, oil, sugar, and other ingredients; and in covering the cemented sheets with a leather or cloth, which is applied with a India-rubber bonding."
Long after the invention of printing and its introduction into England, books were dear. In the ‘Privy Pen Account of Elizabeth of York,’ published by Sir H. Nicoll, we find that, in 1505, twenty pence were given for a Primer and a Psalter. In 1506 twenty pence were given for half a pound of barley, and were equal to six days’ work of a labourer. In 1516 Fitzherbert’s Abridgement, a large folio law-book, the first published, was sold for forty shillings. At that time forty shillings would have bought three fat lambs; books of this size and price must have become cheaper as they spread more widely, partly upon a larger number of purchasers. The exclusive privilege that were given to individuals for printing all sort of books, during the reign of Henry VIII., Mary, and Elizabeth, though they were in accordance with the spirit of monopoly which characterized that age, and were often granted to prevent the spread of books—offering a proof that in that market was not large enough to enable the producers to use the risk of competition. One with another, 200 copies may be estimated to have been printed of each book, during the period we have been noticing; we think that proprietors would have been quite adequate to the supply of the limited number of readers—to many of whom the power of reading was a novelty unsanctioned by the practice of their forefathers.

The second period of the English press, from the accession of James I. to the Revolution, was distinguished by pedantry at one time, to which succeeded the violence of religious and political controversy; and then came the profuse publication of books in that extensive public spirit which was active during the political-religious contest. There is, in the British Museum, a collection of 2000 volumes of Tracts issued between the year 1640 and 1660, the whole number of which leaves us to the publications amounting to nearly 30,000. The number of impressions of new books connected with controversial subjects must have been very small during this period.

After the Revolution an act of parliament was passed that only twenty printers should practise their art in the kingdom. We see by a petition to parliament in 1666, that there were only 140 ‘working printers’ in London. They were quite enough to produce the kind of literature which the country required.

At the fire of London in 1666, the booksellers dwelling about St. Paul’s lost an immense stock of books in quires, amounting, according to Evelyn, to the value of 200,000l., which they were accustomed to store in the vaults of the metropolitan cathedral, and of other neighbouring churches. At that time the people were beginning to read again, and to think;—and as new capital rushed in to replace the consumed stock of books, there was once more considerable activity in the printing trade. The booksellers and printers who had had their hands full of work during the night, and with the great number of our press: they required translations and abridgments of the classics—versions of French and Italian romances, old chronicles, and sermons to delight the people. Caxton and his successors abundantly supplied these wants, and the impulse to most of their exertions was given by the growing demand for literary amusement on the part of the great. But the priests strove with the laity for the education of the people; and not only in Protestant but in Catholic countries, were schools established: the presses everywhere were a new source of employment for the press—A, B, C’s, or Abuses, Primers, Exercises, Grammars, Dictionaries, were multiplied in every direction. Books became as much of a necessity of ‘professional men. There were not many works of medicine, but a great many of law. They were too required instruction in the laws which they were required to obey; and thus the Statutes, mostly written in French, were translated and abridged by Darnell, a eminent law-printer. It was as early as the time of Caxton the press was employed to promulgate new laws.

Taken altogether, the activity of the press of England, during the first period of our inquiry, was very remarkable. To William Caxton, our printer, John Wynken de Worde, the able assistant and friend of Caxton, produced the large number of 450 books from 1493 to 1535, that is, upon an average, he printed 10 books in each year. To Richard Pynson, supposed to have been an assistant of Caxton, and his immediate successor, we are indebted for the first English translation of the Bible, which was printed at about the same time. From the time of Caxton’s press to that of Thomas Hacket, with whose name Dr. Dibdin’s work concludes, we have the enumeration of 2226 books. The ‘Typographical Antiquities’ of the name of the printer, and the number of the book, is given in each, thus 414, 1600. The same authors have recorded the titles (we have consulted the sufficient and complete list of the books printed) of nearly 10,000 distinct works printed among us during the same period. Many of these works however were only single sheets; but, on the other hand, there are doubtless many which have been lost. Dividing the total number of books printed during these 130 years, we find that the average number of distinct works produced each year was 75.

**script to William Caxton: a Biography, by Mr. Charles Knight, which gives a history of the Progress of the Press in England.** The subject may be divided into five periods:—

**I. From the introduction of printing by Caxton to the accession of James I.**

**II. From 1603 to the Revolution, 1688.**

**III. From 1688 to the accession of George III., 1760.**

**IV. From 1760 to 1800.**

**V. From 1800 to 1842.**

On the earliest objects of the first printers was to preserve from further destruction the scattered manuscripts of the ancient poets, orators, and historians. But after the first half-century of printing men of letters anxiously demanded corrections of the ancient classics. Michael Drayton and Stephen Gosson, translators and Plantinas produced neat and compactly printed octavo and duodecimo, in addition to the larger books, instead of only producing the expensive folios of their predecessors. The instant that they did this, the foundations of literature were widened and deepened. They probably at first overrated the demand; indeed, we know they did so, and they suffered in consequence; but a new demand very soon followed upon the first demand for cheap copies of the ancient classics. The first English Bible was bought up and burnt; those who bought the Bibles contributed capital for making new Bibles, and those who burnt the Bibles by so advertising them. The first printers of the Bible were however cautious—they did not see the number of readers upon whom they could rely for a profit. In 1544 Caxton printed only 500 copies of his complete edition of the Scriptures: and yet, so great was the rush to this new supply of the most important knowledge, that we have existing 326 editions of the English Bible, or parts of the Bible, printed between 1526 and 1600.

The early English printers did not attempt what the continental printers were doing for the ancient classics. Down to 1540 no Greek book had appeared from an English press. Oxford had only printed a part of Cicero’s Epistles; Cambridge, no ancient writer whatever: three only or four old Roman writers had been reprinted, at that date, throughout England. The English nobility were, probably for more than two centuries, the great engines of our press: they required translations and abridgments of the classics—versions of French and Italian romances, old chronicles, and sermons to delight the people. Caxton and his successors abundantly supplied these wants, and the impulse to most of their exertions was given by the growing demand for literary amusement on the part of the great. But the priests strove with the laity for the education of the people; and not only in Protestant but in Catholic countries, were schools established: the presses everywhere were a new source of employment for the press—A, B, C’s, or Abuses, Primers, Exercises, Grammars, Dictionaries, were multiplied in every direction. Books became as much of a necessity of ‘professional men. There were not many works of medicine, but a great many of law. They were too required instruction in the laws which they were required to obey; and thus the Statutes, mostly written in French, were translated and abridged by Darnell, an eminent law-printer. It was as early as the time of Caxton the press was employed to promulgate new laws.

Taken altogether, the activity of the press of England, during the first period of our inquiry, was very remarkable. To William Caxton, our printer, John Wynken de Worde, the able assistant and friend of Caxton, produced the large number of 450 books from 1493 to 1535, that is, upon an average, he printed 10 books in each year. To Richard Pynson, supposed to have been an assistant of Caxton, and his immediate successor, we are indebted for the first English translation of the Bible, which was printed at about the same time. From the time of Caxton’s press to that of Thomas Hacket, with whose name Dr. Dibdin’s work concludes, we have the enumeration of 2226 books. The ‘Typographical Antiquities’ of the name of the printer, and the number of the book, is given in each, thus 414, 1600. The same authors have recorded the titles (we have consulted the sufficient and complete list of the books printed) of nearly 10,000 distinct works printed among us during the same period. Many of these works however were only single sheets; but, on the other hand, there are doubtless many which have been lost. Dividing the total number of books printed during these 130 years, we find that the average number of distinct works produced each year was 75.
there were several London papers, regulated however by privileges and surveyors of the press. Soon after the beginning of the eighteenth century (1709) London had one daily paper, fifteen times three a week, and one twice a week: this was before a stamp-duty in 1724 there were three daily papers, six weekly, and ten three times a week. Provincial newspapers had already been established in several places. In 1731, Cave, at his own risk, produced the first Magazine printed in the 'Gentleman's.' This was a great success; and that in the following year the book-sellers, who could not understand Cave's project till they knew its value by experiment, set up a rival magazine, 'The London.' In 1749 the first Review, 'The Monthly Magazine,' was started; and in a few years was followed by 'The Critical.'

The periodical literature of this period greatly reduced the number of merely temporary books; and it had thus the advantage of importing much of the best work of the country. The斑斑点点 deduction for the pamphlets inserted in the catalogues already referred to, still appears that the great influx of periodical literature, although constituting a most important branch of literary commerce, had in some degree the effect of narrowing the publication of new books; and perhaps wholesome so. It appears from a 'Complete Catalogue of Modern Books published from the beginning of the century to 1756,' from which all pamphlets and other tracts are excluded, that in as many as seven years of the above period, which exhibits only an average of ninety-three new works each year. It seems probable that the numbers of an edition printed had been increased; for, however strange it may appear, the general prices of the works in this catalogue were found to be higher than in a few similar catalogues. The subscribers for new books, even at the high cost of subscriptions, had in many cases formed, in the Reading Societies and Circulating Libraries. Those new modes of diffusing knowledge were first established, it was predicted that they would destroy the trade of publishing. By their means the circulation of knowledge was increasing daily, enabling many to read new books at a small expense, created a much larger market than the desires of individual purchasers for ephemeral works could have formed; and a very large class of books was expressly produced for this market.

But a much larger class of society was always being sprung up, principally out of the middle ranks. For these a new species of literature had to be produced—that of books conveying useful information in a popular form, and published at a very cheap rate. The 'Clerk's Pocket Companion,' in 1727, was the first to lead the way in this novel attempt; in the same year the Society for the Diffusion of Useful Knowledge, which had been formed in November, 1826, commenced its operations, and several publishers of eminence soon directed their capital into the same channels. Subsequently editions of our great writers have been multiplied at very reasonable prices; and many a tradesman's and mechanic's house now contains a well-selected stock of books, which, through an annual expenditure of 2s. 6d., has brought in, in the middle of intellectual improvement, and all the tranquil enjoyment that attends the practice of family reading, home to a man's own fireside.

The increasing desire for knowledge among the masses of the people was however still not sufficient. In 1829 the 'Penny Magazine of the Diffusion of Useful Knowledge and Chamber's Journal' commenced to be published; and subsequently the 'Saturday Magazine.' The 'Penny Sheet' of the reign of Queen Anne was revived in the reign of William IV., with a much wider range of usefulness. It was said by some that the trade in books would be destroyed. They asserted also that the rewards of authorship would be destroyed, necessarily, at the same time. The 'Penny Cyclopaedia' of the Society for the Diffusion of Useful Knowledge, which was commenced at this double destruction. The work has returned about 160,000l., to the commerce of literature, and 40,000l. have been distributed amongst the authors and artists engaged in its production, of which 12s. 6d. was a profit, and 10s. 6d. has been ably earned by the diligence of the writers.

There is a mode however of testing whether cheap literature had destroyed the publication of new books, without including reprints and pamphlets. We may examine the relations of the four years from 1805 to 1842, as computed by Mr. J. M'Culloch in the last edition of his 'Commercial Dictionary.'

| NEW WORKS, 1829 to 1832. Value of a single Copy. |
|---|---|---|---|---|
| Year. | Vols. at Publication price. | £ | 6s. | 3d. |
| 1830 | 1641 | 11 | 15 |
| 1831 | 1619 | 9 | 9 |
| 1832 | 1620 | 8 | 0 |

This is a prodigious stride beyond the average of 89 per year of the previous period. From some causes or other, the selling-price of books had increased, in most cases 50 per cent., in others 100 per cent. The 2s. 6d. duodecimo had become 4l., the 6s. or 10s. 6d., and the 12s. quart, 1l. It would appear from this that the exclusive market was principally sought for new books; that the publishers of novels did not rely upon the increasing number of readers; and that the periodical works constituted the principal supply of the trade. The average of the increase of the sales in books must however have become enormous, when compared with the previous fifty years.

V. Of the last period—the most remarkable for the great extension of the commencement in books, shall represent the accounts of the first 27 years collectively, and of the last 16 years in detail.

The number of new publications issued from 1800 to 1827, including reprints altered in size and price, but excluding pamphlets, was, according to the London Catalogue, 19,660. Deducing one-fifth for the reprints, we have 15,888 new books in 27 years; showing an average of 588 new books per year, being an increase of 216 per year over the last 11 years of the previous century. Books however were still rising in price. The 4s. duodecimo of the former period became 6s., or was converted into a small octavo at 10s. 6d.; the 10s. 6d. octavo became 12s. or 14s., and the guinea quarto very commonly two guineas. The demand for new books, even at the high cost of subscriptions, was so great, that the Reading Societies and Circulating Libraries were enabling many to read new books at a small expense, created a much larger market than the desires of individual purchasers for ephemeral works could have formed; and a very large class of books was expressly produced for this market.
The average price of these papers is, as near as may be, 5d.; so that the sum annually expended in newspapers is about 1,250,000L.

The quantity of paper required for the annual supply of these newspapers is 121,184 reams, some of which paper is of an enormous size. In a petition to the pope in 1472, for the suppression of heretics, printed at Rome, they bitterly complain of the want of demand for their book, their stock amounting to 12,000 volumes; and they say, 'You will admire how and where we could procure a sufficient quantity of paper; or even rags, for such a number of volumes. About 1200 reams of paper would produce all the poor printers’ stock. Such are the changes of four centuries.

We recapitulate these estimated annual returns of the commerce of the press:

- New books and reprints: £435,600
- Weekly publications, not newspapers: 100,000
- Monthly publications: 30,000
- Newspapers: 1,250,000

£2,085,600

The literary returns of the United Kingdom, in 1748, were unquestionably little more than 100,000L. per annum. What has multiplied them twenty-fold? Is it the extent of the widening of the market—the exclusion or the diffusion of knowledge? The whole course of our literature has been that of a gradual and certain spread from the few to the many. As the printing press has been for over a century the cotton or the silk trade. Henry VIII. paid 12s. 4d. for a silk gown for Anne Boleyn—a sum equal to five guineas a yard of our day. Upon whom do the silk mercers now rely? The public. One may buy a silk gown at half-a-crown a yard. The printings-chine has done for the commerce of literature what the sack and the Jaccard-loom have done for the commerce of silk.

It has made literature accessible to all. (For an account of the ‘Book Trade of Germany,’ see *Journal of London Statistical Society*, vol. iii.; and the same work, vol. vi., for a notice of the ‘Book Trade in England.’ As to newspapers, see *Newspapers, P. C.*)

B. officinalis. *Common Borage*. This species has a stately tall five-deep spikes; a rotate cymula with the tube very short, the throat with short, erect, emarginate scales; exerted stamens, the filaments bifid, the inner fork bearing the anther; the anthers linear, lanceolate, convoluted in the form of a cone. All the tubular part of the flower is truncate or lanceolate leaves, and blue, paniced, drooping flowers.

B. officinalis, Common Borage, has the lower leaves oblong-obovate, obtuse, attenuated below; the segments of the calyx are ovate-oblong, the flowers are blue, and the whole plant is bipinnate with ciliated hairs. The genus appears to be originally a native of Aleppo, but is now naturalised in most countries of Europe. In Great Britain it is not uncommon and rubbing in waste places. Borage has formerly a great reputation as a cordial. Its virtues in this respect have been overrated, as in common with the whole family to which it belongs, it possesses no very active properties. The tissues contain gum, and on this account it may be used as a demulcent. It also possesses the use of potash, as well as other plants of the order, which renders it slightly terebinthaceous. Withering says the young tender leaves may be used as salads or as a potherb. G. Don has described three other species: *B. cressulaefolia, a native of Persia; B. longifolia, from Numidia; and B. lastiloba, a native of Cornwall*. They are all plants of the easiest culture. They may be always propagated by seed, which should be sown in the open ground. They form pretty border-flowers.

The four years ending 1832 were published, of new books, 6149 volumes; in the four years ending 1842 were published 8097 volumes. The cost of a single copy of the 6149 volumes was 5492L.; of the 8097 volumes, 7560L. The average price of these volumes in the first period was 11s. 6d.; in the second period, 8s. 9d.

Mr. McCallie has also given the following table of reprints, from 1839 to 1842:

Mr. McCallie adds: 'From inquires we have made with much care and labour, we find that, at an average of the four years ending with 1842, 2149 volumes of new works, and 755 volumes of new editions and reprints (exclusive of pamphlets and periodical publications), were annually published in Great Britain; and we have further ascertained that the publication price of the former was 8s. 9d., and of the latter 8s. 2d. a volume. Hence, if we suppose the average impression of each work to have been 750 copies, it will be seen that the total value of the new works annually produced, if they were sold at the publication price, would be 708,494L. 8s. 9d., and that of the new editions and reprints, 231,218L. 15s. We believe however that if we estimate the value at which the entire impressions of both descriptions of works actually sell at 4s. a volume, we shall not be far from the mark; and if so, the real value of the books annually produced will be 435,600L. a-year.

But the most remarkable characteristic of the press of this country is its periodical Literature. It is most of the times, without exaggeration, that the periodical works issued in Great Britain during one year comprise more sheets than all the books printed in Europe in the period of Gutenberg to the year 1800.

The number of weekly periodical works (not newspapers) issued in London on Saturday, May 4, 1844, was about sixty. Of these the weekly sale of the more important amounts to little less than 500,000 copies, or about fifteen millions annually. The greater number of these are devoted to the supply of persons who have only a very small sum to expend weekly upon their home reading.

Of the weekly publications, independent of the sale of many of them in monthly works, we may fairly estimate that the annual returns are little short of 100,000.

The monthly issue of periodical literature from London is unequalled by any similar commercial operation in Europe. 227 monthly and periodical works were sold out, on the last day of May, 1844, to every corner of the United Kingdom, from Paternoster Row. There are also 38 periodical works published quarterly: making a total of 265.

A bookseller, who has been many years conversant with the industry of the great literary hive of London on Magazine-day, has favoured us with the following computations, which we have every reason to believe perfectly accurate:

The periodical works sold on the last day of the month amount to 500,000 copies. Mr. McCallie estimates them at 265,000.

The number of newspapers published in the United Kingdom, in the months of which can be obtained with the greatest accuracy through the Stamp Office, was 447. The stamps consumed by them in that year were 60,529,001. Their proportions are as follows:

1843.

BORDONE, PARIS (Cavalieri), one of the most distinguished painters of the Venetian school, especially in portrait, was born of a noble family at Treviso in 1566. He was for a short time the pupil of Titian in Venice, but they disagreed and separated, and Bordone chose afterwards Giorgiono as his master. He became a pupil of a spiral, and even in current style of his own, which however did not differ in anything material from the styles of these two great Venetian masters. Bordone's works are especially distinguished for all the beauty and interest of carrying the whole skill of his art to the drawing or invention. One of his best works is the Martyrdom of St. Andrew, in the church of San Giolbe at Venice. Vasari mentions the picture formerly in the Scuola di San Marco, now in the Academy, of the Fisherman presenting the Bishop with a fish, an enlargement by the master of his own little invention but though the colouring is rich and the general execution good, the composition is bad, the point of sight, or horizontal line, is placed so high that the spectator has a kind of his eye on the wrong scene; the figures are small; the background is rich architecture, but the perspective is incorrect.

It was taken to Paris by the French during the war, but was restored to Venice in 1816. His picture of Paradise, formerly in the church of Ogni Santi at Treviso, is now also in the Venetian Academy. Other metals have been used, among them a beautiful Holy Family by Bordone, and a picture of Apollo with a Lyre, and Marysia and Midas in the background. Bordone spent some time in the service of Francis I. in Paris, where he died in Venice, in 1570, according to the best authorities, but various dates are given both for his birth and death.

(Zassetti, Della Pittura Venetiana; Ridolfi, Le Maraviglie del disegno in metallo.

BORING INSTRUMENTS. The boring instruments commonly used by the carpenter consist of awls, or broad-aws, gimlets, augers, and bits of various kinds. The first-mentioned, which are only used for very small holes, and generally in soft wood, are solid cylindrical tools ground to a straight chisel-shaped edge, and mounted in round handles, by which they are pressed into the wood with an alternating semi-rotary motion, taking care, in commencing the hole, to apply the chisel-shaped end at right angles to the grain, so as to cut the fibres, instead of the wood, of which the handle is made. 

Gimlets are cylindrical tools hollowed out on one side, and terminating in a short conical screw with a sharp worm tapering off to a point. These, to afford more power, are mounted in traverse handles. Being pressed into the wood with a rotary motion from left to right, the conical screw, directed by its tapering point, cuts its way into the wood, while the sharp edge of the semi-cylindrical cavity or hollow in the side of the gimlet attaches and clears away all the cuttings produced by the point. They are generally used for boring the inner part of the tenon of the joint, or for boring the back of the hole when the hole is made with a brace and bit. Gimlets are made of various sizes, but are seldom used for boring holes except in wood, and are always made to revolve in the same way as the bit of the brace. 

Augers bear a general resemblance to gimlets, but are so large that their traverse handles are worked by two hands, while gimlets are used with one hand only. Sometimes the counters are made very similar to those of a gimlet, but in other cases there is no screw, the end of the instrument being formed more like a centre-bit. In other cases, again, the semi-cylindrical hollow or cavity which receives the boring, and by the sharp edge of which the sides of the hole are trimmed, is formed by the worm of the auger turned round the axis of the instrument, which then gradually tapers into a conical screw. Both augers and gimlets are made smaller at the upper part, nearer the handle, than near the end, which is the opposite to the case of boring tools. 

Bits are boring instruments made to fit into a large crank-shaped handle turned a brace, by which they may be applied with greater power and precision than gimlets or augers, and are used for boring holes which are more distant from the axis of the instrument in accuracy is necessary, and for boring hard woods. They are made in sets, and are readily fixed in or detached from the brace by means of a spring. The principal kinds, as enumerated in Nicholson's Architectural Dictionary (article 'Bit'), are shell-bits, which resemble such augers as have no screw at the end, but simply an interior cylindrical concavity, with a cutting edge. Centre-bits, which, as their name implies, turn upon a centre or projecting point in the middle of their breadth as upon an axis; they are of a flat or chisel-like shape, and have a vertical cutting edge projecting from the extremity at one side, so as to cut the wood across the grain round the circumference of the hole, while on the opposite side of the axis or centre is a radial cutter projecting obliquely, but almost horizontally, from the face of the bit, which, as the instrument is turned round, ploughs away, in the inner side of the cylinder, the concavity of the head of the vertical cutter. Such an instrument may be compared to a revolving plough, the vertical cutters representing the coulter, and the radial cutter the ploughshare; and, as it cuts clean large holes with but little risk of splitting. Taper-drills are used to enlarge holes in wood; and rammers are pyramidal bits, with a vertical angle of about 34°, the cross section of which is either polygonal or semicircular, used in like way as the auger or iron for boring holes, and for enlarging holes of scraping rather than boring; and those of a polygonal shape are intended especially for iron. Instruments of the same kind, mounted for use in the hand instead of a brace, are called broaches. Countersinks are made with a vertical angle of about 90°, used for widening the upper part of screw-holes, so as to allow the heads of screws to be countersunk into them. Those for iron have generally but two cutting or rather scraping edges; but those for wood and the softer metals have more. The countersink is made to form on the conical surface of the bit. A screw-driver is frequently added to a set of boring-bits, and used, like them, in the brace.

Small holes in metal are usually bored with drills or boring-bits formed with scraping rather than cutting edges. These frequently resemble the countersinks used for iron, but are sometimes made more in the shape of a centre-bit. They are occasionally used in a brace, and where the pressure required is greater than can be applied by the conical screw. They are placed against the chest of the workman, an apparatus termed a press-drill is used, in which the brace is pressed to its work by a weighted lever. Some drills are used in a kind of stock which receives an alternating rotary motion, and is worked by hand, the tight string of which is passed round a pulley fixed upon the stock, and rubbed with resin to prevent the slipping of the string. Another simple and effective mode of working a drill is by fixing it in the lower extremity of a vertical spindle, and turning the upper end of the vertical spindle by a wheel. The pressure of the opposite extremity with a heavy circular mass of metal to give it an impetus. A strong cord is passed through a hole in the upper extremity of the spindle, and is attached to the opposite end of a transverse piece of wood which, by means of a hole in the centre of the wood, is slipped upon the spindle, and is capable of moving up and down freely upon it. Before using the drill the transverse piece of wood must be turned round two or three times, so as to wind the spiral round the spindle half way, or to the required part of the circumference. The drill between the wood, set in the required place, and the spindle placed in a vertical position, the transverse bar is pressed almost downwards by the hand. By this action the cord is unstretched, and the spindle turns much more rapidly than before, so that the pressure is sufficient to wind the cord round it in the opposite direction, and thereby to lift up the transverse bar, the pressure on which is relaxed for the moment. A fresh application of pressure again unwind the cord, and occasion the bit to revolve in the opposite direction, and by a repetition of the same operation the spindle is kept in very rapid motion, though revolving alternately in opposite directions. This ingenious invention is derived from the native smiths of Ceylon.

Common drills are frequently used, especially for very delicate purposes, in a lathe, and all the larger operations of metal-boring, such as the boring of musket-barrels, cannon, and the cylinders of pumps and steam-engines, are performed by boring machines of the same general construction, the boring of guns being briefly alluded to under Cannon, P.C., p. 242. Musket-barrels are bored with a cylindrical plug of tempered steel about an inch and a half long, with its surface cut like a perpetual screw, with a flat thread about a quarter of an inch thick. The cylinder is made by fitting it on a lathe, and rendering it with a very smooth surface, and thus a very efficient boring implements, which, it must be remembered, has not to make a hole, but simply to remove inequalities from the inner surface of a cylinder formed by revolving or rolling. In the early manufacture of steam-engines and similar machinery the difficulty of procuring accurate cylinders formed a great obstacle to improvement. The old method of boring cylinders and pump-barrels resembled the plan adopted for boring wooden water-pipes, which was to place the pipe in a carriage made to move forward as nearly as possible in the direction of its axis, against a revolving.
borax or barium and giving rise to oxalic acid and calcium oxalate. These substances are excreted by the roots and accumulate in the soil, forming a white deposit on the surface. This deposit is known as tufa, which is a calcareous concretion and is often found around springs or in carbonate-rich water bodies. The borax deposits are a result of the crystallization of sodium borate in the presence of groundwater enriched with boron and calcium. The precipitation of these minerals is influenced by the chemical composition of the water, the presence of dissolved gases, and the temperature and pH of the environment. Understanding the factors that contribute to the formation of borax deposits is crucial for managing water resources and preventing the clogging of water sources, irrigation systems, and drainage channels. Research in this field has led to the development of methods for extracting borax and using it as a valuable resource.
principles. He was ordained, on the 91st of September, 1809, minister of the parish of Simprin, near his native place. In 1707 he was "translated," as it is termed, to the extensive but thinly peopled pastoral parish of Etrick. He was a member of the General Assembly of 1708. While this assembly was in the midst of its labours, and he was becom-
able to the court, it was dissolved by the commissioner, and the moderator, who, according to the theoretical principles of that ecclesiastical body, is the conductor of its routine, sanctioned the act by concluding the proceedings. Boston and others strongly protested against this compromise of clerical inde-
dependence. He was opposed to the oath of abjuration, and in general to all measures which created restrictions on the inde-
pendent movements of the ecclesiastical body to which he belonged. In 1709, he wrote his "Discourse Concerning the Marriage of Modern Divinity," in the controversy in the Scottish Church on that work. He died on the 20th of May, 1782. He was a very voluminous writer, and his works are extensively read in Scotland, and among the Presbyterians of England. His well known "Four Fold State," which was first printed in 1790, had a curious literary fate. It had been so far reconstructed by a person whom he had engaged to correct the press, that the author, scarcely recognising his own work, republished a reprinted edition in 1794. The title of this book in full is, "Human Nature in its Four Fold State : Of Primitive Integrity subsisting in the Parents of Mankind in Paradise; Entire Depravation subsisting in the Ungenerate; Begun Recovery subsisting in the Regenerate; and the Final堕落 subsisting in the Inhabitants of the Universe kind in the Future State." In 1796 there was published "Memoirs of the Life, Time, and Writings of Thomas Bos-
son, divided into Twelve Periods, written by Himself and addressed to his Children," a work containing quite as ample an account of this writer as the majority of readers will wish to possess.

BOTANY, FOSSIL, The progress now making in the examination of the structure of fossil plants by microscopists, is such as to induce a postponement of the results till a later period. [Plants, Fossil, P. C. S.]

BORODEENRON [Lodoreon, P. C. S.] 

BOTRCYMUS, a genus of fenns belonging to the sub-
order Cymodoceceae and the tribe Ophioglossaceae of that family. It has distinct threes disposed in a compound spike attached to a pinnate or bi-pinnate frond. There is only one species a native of Great Britain, the B. Lunaria, Common Moon-
wort. It has a solitary pinnate frond, with notched or crenate, lanceolate or fan-shaped pinnule. This is not a very conspicuous fern, but has been observed in almost every part of Great Britain. It grows on dry open heaths, elevated pastures, and waste lands which are generally shunned by other species of ferns.

In former times the ferns had a great reputation in medi-
cine, not so much on account of their obvious as their sup-
pposed virtues. The lunate-shape of the pinnule of this fern gave it its name and was the origin of much of the supersti-
tion of the Pliny and other old writers. The fern was especially gathered by the light of the moon. Gerarde says that it is singular to heal green and fresh wounds. It hath been used among the alchemists and witches to do wondres withal, who say that it will loose locks and make them to fall, hath the feet of horses that garse where it doth grow, and hath been called of them Martagon, whereas in truth they are all but drowsy dreams and illusions; but it is singular for wounds as aforesaid. Its healing powers are now however as much discredited as the French occupation of the island under the Bourbon dynasty. At the end of March, 1815, Napoleon's restored government appointed him Rector of the University of Nancy, which seems to show that he had turned round again with the crowd. He resigned his chancellorship at the second Bourbon restoration, but was ap-
pointed instead Rector of the University of Rouen, an office which he did not retain long, for in 1816 he was living at Paris as a foreigner without employment or pension. He then ap-
plied himself to write a contemporary history of Italy, in which the French occupied the city, and the growing of angry passions which had not yet had time to subside. He determined to write "the whole truth," as far as his means of information went; to speak with honest sincerity, not only to the French of the day, but to all of the future, to the friendless, to the few, to the en-
musicant of nonsense; to make a novel course after emerging from the inquisitorial system of Napoleon, when subserviency alone was praised, and resistance and independence were vitu-
perated and hunted out. Botta commenced this work, told him that he "either dared not or could not abide by his determination, and that even supposing that he dared and could, he ought not to do it." Luckily he persisted, and disregarding the prejudices of men of all parties, the Volneyists and liberal writers, of the Buonapartists and ultramontanists, he produced a book which went far to redeem Italian literature from the charge of almost Oriental servility which it had incurred during the period of Napoleon's reign. Alone perhaps among the nations of Europe, the Italian, or rather, a numerous and active class among them,
had, or thought they had, reason to regret the fall of that reign, when they found themselves placed in a false position; their wishes and national aspirations being opposed to those of the other European nations who had risen against the despotism of the conqueror. Italy had enjoyed fifteen years of peace and of internal harmony, but it was not a peace of tranquil promises of an eventual national union of the whole peninsula, which however appears to have been far removed from its thoughts; and it had meantime obtained considerable influence in the councils of the central powers, and obtained its recognition as a national institution. No wonder that the bold, the strong, the aspiring, among the Italians, should regret Napoleon and confound his cause, as many of the French have done and are still doing, with that of social progress and freedom. Botta displayed his talents for aileding a task, not disdaining to conclude the advocates of old absolutism. He published his work at Paris in 1824: 'Storia d'Italia dal 1750 al 1814,' 4 vols. 8vo. The book was assailed by strictures and denunciations, some of them very abusive and personal; but it stood its ground, went through numerous editions, both in Italy and abroad, and it has long since taken its place in every Italian library. The work is one of lasting interest: the author excels in the description of stirring events, the bustle of the camp, the alarms of a siege, the din and tumult of triumphal processions, the calamities of the devoted inhabitants—the victims of famine, pestilence, or the sword. His account of the insidious arts used by the French directory towards the disarmed court of Sicily, of the fall of Venice which this re-division of 1799, the march of Suarow, the battle of Novi, the siege of Genoa, the dreadful massacres of Naples, the pass of the Splugen by Macdonald's army, Napoleon's coronation at Milan, the revolution of 1796, the evacuation of the French from Calabria, and Ali Pasha, the horrors of the war of extermination in Calabria, are all masterly sketches. His style however is upon the whole unequal, and his sentiments at times seem inconsistent with one another. He is not always successful in drawing individual characters, or in scanning the internal workings of men. Some of his battle descriptions are somewhat confused. There is also a disproportion between the various parts of the work; twenty books are bestowed upon the Italian civil and political history from the peace of 1748, at Vienna, in 1801, and only seven upon the subsequent period down to 1814. But notwithstanding these faults, Botta's history is a noble work, and one that does honour to Italian literature.

Encouraged by the success of this work; a certain number of Italian and French lovers of literature urged Botta to attempt a continuation of Guicciardini's history of Italy, from 1550, down to 1775, so that the end should meet the beginning of his 'History. These friends made a subscription among themselves sufficient to allow him to receive a decent annual income during the time that he should be engaged in his laborious undertaking. Botta accepted the task in 1826, and he completed it at the end of 1830: 'Storia d'Italia in Continuazione dal 1775 al 1814' Paris, 10 vols. 1832. This larger work was received with applause, owing in part to the author's already established reputation as a historian. The Academy of La Cruscia bestowed upon the author its decennial prize; and Charles Albert, king of Sardinia, created him a knight and gave him a pension. This was the first token of favour obtained by Botta from any government for his writings, and, it is well to observe, that it was for the old and not for the contemporary history that it was granted, and therefore could not affect Botta's character for independence. In fact Botta lived and died poor. In 1832 Botta revisited his native Piedmont, and was very favourably received there. He afterwards returned to France, whose king, in 1835, made him a member of the Academy of Science, a medal of first class of the French Institute, and a pension.

Besides the works mentioned in this article, Botta wrote—
1. 'Il Camillo, o Vejo conquistato,' a poem, Paris, 1815; 2. 'Storia dei Popoli Italiani da Costantinopoli a Napoli,' a compilation published first in French in 1825, and afterwards in Italian in 1826. His history of American independence has been translated into English, by Oris, and has been greatly praised in the United States. As a literary work however it is much inferior in merit to the two histories of Italy.

(Tipaldo, Biografia degli Italiani Illustri: Foreign Quarterly Review, No. 1, July, 1827, article on Botta's 'History of Italy'; Dr. Boer's Life of Botta, in the same journal, A Review of his 'Continuation of Giuc."

BOTTOMRY BOND. [Bottomry, P. C.]

BOUCHARDON, EDM., a distinguished French sculptor, was born in Seine et Marne, in 1730. He was instructed in his youth by his father, who was likewise a sculptor and architect; and, after he had made sufficient progress, he entered the school of the younger Coston at Paris, where he remained five years, when he went to Rome, and was decorated with a prize of the Royal Academy in 1729. By this prize he was entitled to study for a limited period at Rome, at the expense of the French government, in the French academy established there by Louis XIV. Bouchardon remained at Rome for ten years, during which time he was much employed, especially in busts, and he was selected to execute the monument to Clement XI.; but, being recalled by the French government about the same time, he did not execute it. He returned to Paris in 1732; in the year following he was elected Agedé, in 1744 a member, and in 1746 a professor, of the Academy of Painting and Sculpture. He died at Paris in 1792. Bouchardon's principal works were the Fontaine de Grenelle, and the equestrian statue of Louis XV. The Fontaine de Grenelle was executed in 1770, when Bouchardon was 39 years of age, and was first exhibited in 1739 and finished in 1745: the inscription is by Cardinal Fleury. The authorities of Paris, by whose order it was made, were so well satisfied with its execution, that they voted Bouchardon a pension for life. He then executed the equestrian statue of Louis XV., which was of marble, was placed in the Place Louis XV. in 1763, and was destroyed by the populace in 1792. Bouchardon was occupied in its execution during twelve years, yet it was unfinished when he died: the pedestal was executed by Figari, who was also chosen by Bouchardon himself to complete the monument. It was engraved by Catheline. There are also some statues by Bouchardon in the church of St. Sulpice, and in the gardens of Versailles, Choisy, and Gravelines, and a large sculptor to the king. Many of his works and sketches have been engraved, and there are a few etchings by his own hand.

J. J. Preisler engraved fifty antient statues from drawings by him. Count Calvius engraved many others, besides several of Bouchardon's original works; but it was also chosen by Bouchardon himself to complete the monument. He died at Paris in 1792, or, according to another, 1770, director of the academy.

Boucher was a painter of very great ability, and had extraordinary facility of execution, but he disapproved every cor- rect principle of execution to a picturesque effect, which consisted in a more variegated tissue of light and shade. His figures are utterly void of expression. His subjects were chiefly mythological, amorous, and pastoral, and he peopled the whole of Fennel, the temple of a nymph, and the scene of the union of pure taste, partly effected by Watteau, was fully accomplished by the works of Boucher, for though in his time a great popular favourite, his style has been subsequently condemned in the very strongest terms, even by his own countrymen. The French have called the Ancien de painters, a compliment (if one) which, though it may apply to Boucher's subjects, cannot apply to his execution of them. His designs are extremely numerous, amounting to several thousands; and a great many of them have been engraved; a few by himself, and others by upwards of 140 different engravers, French and foreign.

(L'Abbe de Fontenel, Dictionnaire des Artistes; Heineken, Dictionnaire des Artistes, &c.; Watelet and Leravoix, Dictionnaire des Arts, &c. Bouche, Louis.)
BOUFFLERS. There were two remarkable females often mentioned in the literary history of the eighteenth century who bore this title, and who are frequently confounded with each other. The one was the N. Micheli; the other was the N. de Boufflers-Renémerou, a correspondent of Voltaire, and the principal female ornament of the court of Stanislaus Augustus of Poland. She was a great reader, and wrote some pleasing verses. The other was the Comtesse de Boufflers-Rouvrel, who is perhaps better known in the English classics for all his drollery and the satirical satires of the Prince de Conti, and on the death of her husband, in 1764, was disappointed at not becoming the wife of that prince. She fell in love with an Englishman, and the suitor. Several editions of her English letters show that she was a very accomplished woman.

BOULDER FORMATION, in Geology, a title now introduced to supplant that of diluvial deposits. Till is an equivalent term employed in Scotland. By these accumulations are ranked in the ill-defined class of Pleistocene deposits.

BOURNE, VINCENT, was probably born three or four years before 1700, but the date of his birth does not appear to have been recorded. He became a king's scholar in Westminster School in 1710, whence he was elected to be sent to Trinity College, Cambridge, in 1714; he took the degree of A.B. in 1717, and that of A.M. in 1721. He obtained a fellowship at Trinity, and was admitted to the Mastership of Westminster School, in which situation he seems to have continued for the rest of his life. He never took orders. He died December 2, 1747.

Vincent was the author of a considerable number of short Latin poems, of several translations of short English poems into Latin, and of a few epitaphs in Latin and English. He is an exceedingly pleasing writer. He has great originality and variety of thought, and great vivacity of imagination, often combined with a delicate humor quite peculiar to himself. His subjects are generally occasional and of little importance; but the treatment is very delightful, and entirely free from classical or any other commonplaces. His Latin is refined and elegant, and his composition is without a flaw; his style is exquisite, and his versification has a facility and harmony not surpassed by any modern writer of Latin poetry.

Some of Bourne's Latin translations are of poems admired ones, but little valued now, such as Mallet's 'William and Margaret,' Rowe's 'Colin's Complaint,' and Tickell's 'Lucy and Colin;' but the versions are of singular excellence, retaining every trace of thought and expression which is really poetical, and improving, without appearing to change, the style, imagery and spirit; and the formal language of the originals: the trivial and monotonous versification has also disappeared, and the poems have assumed a propriety and grace to which they had previously little claim. In poems of a higher poetical character, such as Gay's beautiful ballad of 'Black-cloaked Squire,' and his 'Hymn to the Sun,' and is distinguished by a fidelity which, to those who know the difficulty of approximating two languages so dissimilar in structure, is as curious as it is admirable. But even here he gives an occasional heightening touch; for instance, in translating the exquisite simile

"So to the sweet lark, high born in air,\nErects his pinions to his breast,\nIf the his hue be not too bright,\nAnd drops at once into her nest,

Bourne not only poises the lark, as Gay has done, but he gives the vibrating motion of the wings, so characteristic of the lark when singing. He has also transposed the second and third lines, in which Gay has obviously inverted the natural order of thought for the sake of the rhyme:

"The Dick; the Jackal; The Parrot; The Cricket, and\n"The Glow-worm," in none of which, skilful as he was, has he equalled his original. Cowper speaks of Bourne in one of his letters. As he was well situated in the world, and well qualified to appreciate the value of his poetry, it is worth while to give the passage entire:—"I love the memory of Vinny Bourne. I think him a better poet than Tullibius, Persius, Petronius, and all the rest I am acquainted with. Ovid, and not at all inferior to him. I love him with a love of partiality because he was the usher of the fifth form at Westminster when I passed through it. He was so good-natured and so indolent, that I lost more than I gained by him, for he made me as idle as himself. He was such a sloven as if he had trusted to his genius as a cloak for everything that could disgrace you in his house. And if he has any writings no almost made amends for all. His humour is entirely virile; he can speak of a magpie or a cat in terms so exquisitely appropriated to the character he draws, that one would suppose him animated by the spirit of the creature he describes. And in his character of Tullibius this is also the case, and he makes the poet so contemptible at nobody's expense; who is always entertaining, and yet always harmless; and who, though always elegant and classical to a degree not always found in the classics themselves, charms more by the simplicity and playfulness of his ideas than by the neatness and airy manner of his verse. Yet such was poor Vinny. I remember seeing the duke of Richmond set fire to his gossipy locks, and box his ears to put it out again."

The first edition of Bourne's 'Pomastia' was in 1734, 8vo. To the third edition, in 1743, an appendix was added of other translations and poems, forming nearly one-half of the whole collection, 'Pomastia, Latin partam redditus, partam scripta,' a V. Bourne, 12mo. There was another edition in 1750, 12mo. In 1772 a handsome volume in 4to. was published by subscription, 'Miscellany of Translations in the Latin Tongue,' by Vincent Bourne, formerly of Trinity College, Cambridge, and Usher of Westminster School.' It contains a few additional poems, and two letters, one to a young lady, and another to his friend, the late Charles Bannister; also 'Poetical Works, with his Letters,' 2 vols. 12mo., was published in 1808. We have not seen this edition. There has since been another edition in one vol. 12mo.

BOVISTA, a genus of plants belonging to the natural order Fungi. This name was given it by Dillenius, and is a Latinised version of Bofist, its German name. In many parts of England its common name is Bull-fitch or Bullhead, and in Scotland it is called Bull-pawl. The genus Bovista was at one time included under Lycoperdon [Lycoperdon, P. C.], and the type of the genus, Bovista gigantea, was called by Linnæus Lycoperdon Bovista. The present Lycoperdon Bovista is the common or wolf-pawbell. The difference between the genera is, that Lycoperdon has a single peridium, while Bovista has a double one.

The Bovista gigantea, Bull-Pawbell, Frog's Chees, and Bull-eye, is interesting on account of the peculiar nature of its fruiting-bodies. It attains. It has the form of a flattened ball, at first of a perfectly white colour. Specimens have been gathered measuring as much as nine feet in circumference. When they have attained their full size, they begin to change colour; the outer peridium bursts at the apex. The interior is composed of a mass of tissue, which when young is white and moist, but at length becomes coloured and dry, and on being pressed emits a large quantity of powder as matter, which, on being examined, is found to consist entirely of spores. On examining the mass inside, it is found to consist of filaments which are mixed with spores. Burnett says, 'It is probably the smoke that clouds the surface of these fungi whilst they are burned, or some of their allies the Lycopérdes, which forms the secret method advantageously employed by some persons who keep bees, in order to supply the insects without killing them, while their hives are being robbed of all their honey. Gerardo says, 'The common people generally used this fungus for food, or to burn.' He also says, 'In some parts, where the neighbours dwell far aunder, it is used to carry fire from place to place, whereof one species took the name of Lucernoram fungus.' It is used also at the present day in many parts of the Continent as a tinder, by the name of German tinder. The dried inside of this fungus was also at one time in great repute among surgeons as a styptic. A small pledge of it was always employed to cover the wound made in bleeding. It is now seldom used, except for that purpose. This plant is small; it is calculable. An Italian species, the D. furfuracea, which grows in great abundance on the heaths near Florence, is collected and sold in the markets, and, according to Micheli, is esteemed a delicacy (Bois, "Medicinisch - Pharmaceutische Botanik"; Burnett, "Outlines of Botany.")
BOWDITCH, NAthalien.
The materials for the life of Dr. Bowditch are contained in a very full and interesting account, written by his son, and prefixed to the fourth and posthumous volume of his translation of the ‘ Mécanique Céleste.’ There are also before us ‘Eulogy on Nathaniel Bowditch,’ by John Pickering, Boston, 1838; ‘Discourse on the Life and Character of Nath. Bowditch,’ by Daniel Appleton White, Boston, 1838.

Dr. Bowditch was born at Salem, in Massachusetts, March 26, 1773. His family is traced to one of three brothers who emigrated from near Exeter at the beginning of the seventeenth century. His father was a poor working cooper, and could not give his son more education than he himself had. Bowditch, however, was quick to learn; he committed to memory the accounts of the new almanac for the year 1760. He learnt the elements of geometry and algebra by himself, and was taught navigation by an old British sailor. He taught himself Latin that he might read the great books of science, which he could get hold of by the age of twenty-one. At different times of his life he also taught himself, in some cases with a little assistance, most of the European languages; his plan was to translate the New Testament and a dictionary, and begin to translate, writing down the words, as they came into his head. Bowditch was a devoted student; he was an excellent navigator, and on one occasion found his way into St. Helen’s Bay, and in a dark and snowy night, with no other guide than his own reckoning and one instantaneous glimpse of the light on Baker’s Island. He taught every man on board his ship how to find a ship’s place, and on one occasion had twelve seamen, being all his crew, every one of whom could take a lunar observation. He edited three editions of the celebrated work on navigation by John Hamilton Moore; but at last he had corrected so many errors, and made so many changes, that he thought himself justified in publishing it under his own name, and in a new American edition; it is a dear thing to me by Steely.’ In this form it went through eight editions, and became very well known. His maritime life ended in 1804; in 1798 he married, but his wife died before the end of the year. He spent the next six years in Newburyport, leaving a grown-up family. To the memory of this lady his translation of the ‘ Mécanique Céleste,’ of which we shall presently speak, is dedicated.

In 1804 he was appointed to the presidency of the Essex Fire and Marine Company at Salem, a situation of emolument, which he held until 1823, when he accepted another and a still more lucrative appointment, the actuaryship of the Massachusetts Hospital Life Assurance Company, at Boston. He had been actuary of a large insurance company for such a long time that, after making all allowances for filial and friendly partiality in the accounts above named, we must say they ought to have been published even though their subject had not attained any reputation of another kind.

Dr. Bowditch was the author of a good many papers in the Transactions of the American Academy, all on astronomical subjects: one in particular is on an extension of Napier’s rules (vol. iii. pp. 35-58), by which they are applied (it is said) with great success. He is also said to have compiled a table which will carry his name down in Europe, and which entitles him to be considered as the first great promotor of mathematical analysis in the United States, is his translation of the ‘ Mécanique Céleste’ of Laplace, with a commentary. For this the most accurate and complete English translation of the original, are completed and published, the last posthumously, Boston, 1829, 1832, 1834, 1839. The publication was substantially ready in 1817, but was deferred, among other reasons, by the expectation that Laplace himself would publish another edition. To the third volume is added a volume of appendix (Boston, 1844), containing the translator’s collection of methods for computing the orbits of comets from observations, with auxiliary tables. All this was done at Dr. Bowditch’s sole expense, with the cheerful consent of his family; the dedication above mentioned expressly states that ‘the public service would not have been undertaken without his wife’s consent.’

The commentary is valuable, not only as giving the reader of Laplace more recent views and simplifications, and guiding the mind through the vast details of the whole great work, but by bearing upon the text, but also as a real and effective running explanation of all the innumerable steps which Laplace has omitted. Bowditch said, ‘I never came across one of Laplace’s “Thus it plainly appears” without feeling sure that I have failed to get at the point of it, and that I must go back and find out and show how it plainly appears.’ We remember ourselves asking a distinguished extender of Laplace’s views, what were the existing helps to the reading of the ‘ Mécanique Céleste,’ and getting for answer ‘A ream of paper and several hundred of quills.’ There was no facilitating comment in existence, except on detached portions; and Dr. Bowditch supplied this defect in a sound working manner. It is easy to see that his explanations are for the most part those by which he himself was guided in his work of elucidation in bringing his reader. A mathematician, who thought more of his own fame than his reader’s progress, would have discontinued to publish the plain straightforward explanation of Laplace’s methods. But Bowditch was precisely such as a student of the most successful class manages to supply for himself. But this is the beauty of Bowditch’s commentary, as a comment; and appears to us well worth the results of reading which appear in many of the notes, and which, though intended for use out of place, rather extended to explain. As a whole, and independently of its author, this translation is a great undertaking; as the work of a self-taught man, closely engaged in professional business, it is a wonder.

Dr. Bowditch bequeathed his library to the state of Massachusetts, and it forms the commencement of a public library, named after him, at Boston.

BRACcio ForteBRACci, cAllEsd als BRACcio da Montefeltro, by the grant of his patrimonial estate, was born at Perugia, A.D. 1436, of an old patrician family. Bracio, before he was twenty, served as a Condottiere, or leader of a mercenary troop, in the service of the Count of Montefeltro against the Malatesti family of Rimini. In 1468, when a general insurrection of the popular party took place at Perugia, in which a number of the nobles were killed and the remainder driven away, the castle of Montone became a rallying-point for the exiles, and Braccio one of their most zealous supporters. He held the castle for a few months, but found himself unable to defend it and retired to Montone. He engaged in various enterprises of every kind for several years, the popular party applied for protection to Gian Galeazzo Visconti, the powerful Duke of Milan, and paid allegiance to him in January, 1460; and after the fall of Visconti, in 1476, to Alfonso the Second of Aragon, Duke of the two Sicilies, and King of Naples. In 1477, he submitted to Pope Boniface IX., under the plea of ‘the welfare of the Republic,’ on condition that the emigrant nobles should remain in banishment. Braccio now resumed his life of a Condottiere, and served in Lombardy under the great leader Alberico da Barbiano. He afterwards carried on a partisan warfare on his own account, in the Marches of Ancona, against the Marquis Ludovico Miglonari, the nephew of Pope Innocent VII., when he levied contributions, plundered towns, and destroyed the common property of the cities. In 1482, he was invited to the court of the King of Naples, which was at that time under the government of the Papal States and all central Italy, and he set himself to Braccio in 1489, to induce him to enter his service, promising to forward his views towards the subjection of his native town, Perugia. Braccio accepted the proposal, received a sum of money for his troops, and immediately set out. In 1490, he occupied the head of a considerable body of horse and foot, he scoured the valley of the Tiber and took several towns in the name of the king. The people of Perugia, in alarm, sent ambassadors to Ladislas, who was then at Rome, and offered him the de-
231

Braccio, being joined by other bands of the Aragonese party, was in possession of the whole Abruzzo. In December, 1423, Sforza, on the advice of Alfonso, made common cause with Lelio Anjo, ordered Sforza to march to the relief of Aquila. Braccio, being joined by other bands of the Aragonese party, was in possession of the whole Abruzzo. In December, 1423, Sforza

B R A

mishan of their city, provided he would not let the emigrants return. 'Rather than make peace with the nobles,' said the leaders of the people in the council, 'we will submit to a foreign king.' Ladislaus accepted, in June, 1408, the duchy of Naples of the Pope, who promised him that he should have the island of Capua as a fief. He agreed that the emigrant nobles should not be allowed to remain within thirty miles of the gates of Perugia. He also sent a large body of Neapolitan cavalry to attack Braccio, who, having received timely information, retired to the Marches. From Rieti, Alfonso went to the king of Sicily; the king of Sicily, who was at the same time offered to Braccio the command of his land forces, with the rank of high-constable of the kingdom, and paid him down two hundred thousand ducats to advance. 1416, Braccio had fallen in love with his cousin, the Princess of Abruzzo, with a large force, surprising by the rapidity of his march the partisans of the Anguinas, who submitted, except Count Caldora, who took refuge in the mountains. Sforza capitulated. Braccio, lassoing out of the defiles of Abruzzo, surprised Capua, and suddenly appeared before Naples, which was then besieged by Sforza and by the fleet of Louis of Anjou. King Alfonso meantime arrived with his fleet at the entrance of the bay; Sforza was obliged to raise the siege, the Anguinas retired to Castellamare, and Braccio entered Naples in triumph with King Alfonso, who, together with Queen Joanna, solemnly bestowed upon Braccio the golden staff of high-constable of the kingdom, with supreme command over both the Neapolitan and Abruzzese forces, and agreed to give him the crown of Naples, which was bestowed upon him by the nobles. 1416, in the course of the summer, the two rival chiefs, who had both served in their youth under Albertico da Barbiano, renewed their former acquaintance. But Braccio having been now in Capua, which he had not been in since 1415, he returned to Perugia, after having taken on his way Città di Castello, which he added to his other territories.

In the following year, fresh disturbances having broken out at Naples, Alfonso sent again for Braccio, and Queen Joanna gave the messenger a crown to present him as Prince of Aquila and Capua, with full power to subdue and govern the important province of Abruzzo, which had again revolted. On the 18th of February, 1423, the Lord, seated on a seat of state at the great palazzo del Capitano, was attended by the lords of Foligno and Camesino, received the Neapolitan envoy, from whom Corrado Trinci, lord of Foligno, having received the crown, placed it on the brow of Braccio and a golden chain round his neck, amid loud aclama-
ations of 'Long live the Prince of God! long live the Prince of Aqui-
la.' As the dominion of Braccio extended over great part of Umbria and the Marches, and on the south over the prin-
cipality of Capua, the acquisition of Aquila and the Abruzzo would have joined those two portions so as to form the whole into a compact principality. Braccio's ambition is said to have soared still higher, and to have aspired to the crown of Naples. In May, 1423, he gathered his bands near Todi, to the number of 9000 horsemen and some thousand foot, and made common cause with the kingdom of Naples, and through the province of Campania and Apulia, defeated the partisans of the Angevins, took Bari, and advanced into Calabria; then retracing his steps towards the Abruzzo, he laid siege to the strong town of Aquila in the name of Joanna and Alfonso, whose commission he bore. The authorities replies that they were liege of their queen, and that as she was at that time in durance in conse-
quence of the dissensions which had arisen between her and Alfonso, they were unable to obey his orders. Upon his return harmony was restored in the capital and at the seat of government. Braccio then blocked the town and devastated the surrounding country. Joanna, who had now revoked her former act of submission to the crown of Naples, being joined by other bands of the Aragonese party, was in possession of the whole Abruzzo. In December, 1423, Sforza began his march from Apulia along the coast of the Adriatic, took Ortona, and crossed the river Pescara near its mouth, his advanced guard making their horses swim through the stream.

...
As the body of Sforza's army remained on the opposite bank, Sforza plunged again into the river to encourage them to cross. One of his men, being carried away by the current, was in the act of drowning, when Sforza pushed his horse forward to rescue him; but the current was so strong, that the horse and the man were both swept away to the deep and water disappeared. Thus died Sforza Attendolo, the great Condottiere, on the 4th of January, 1442. His army, disheartened, retired from the Abruzzo. Braccio, who was at Chieti, used the news, and the name of his father, to make some pretense that this unexpected catastrophe boded no good to himself. He however pushed on the siege of Aquila with renewed vigour. The town began to suffer through famine. The archbishop encouraged the besieged by telling them that he had heard the Turks intended to suppress the Papacy. Braccio, who had communicated Braccio in the name of the pontiff. At last, in the spring of 1424, the Anghin army, led by Count Caldora and other chiefs, marched into the Abruzzo, and encompassed on the hills above Aquila. Braccio drew out his troops in the plain below in order of battle. His officers entreated him to attack Caldora's soldiers as they came down the defiles of the mountain and before they could form, but he obstinately refused, saying that he wished to fight the whole force of the enemy and to decide the question at once. The battle was fought on the 2nd of June. Caldora's army was greatly superior in numbers, and in the midst of the fight a sortie from the people of Aquila, falling on the rear of Braccio's line, deprived the latter of proportion. Braccio, while giving quarter on the left, received a blow on the head and fell senseless. He was taken prisoner to the camp of Caldora, and treated with humanity. He survived for three days, refusing to take food, though urged to do so, and would not utter a word. He said he had not more than thirty-five years. He died on the 6th of June, 1424, in the fifty-sixth year of his age. Rome rejoiced at his fall; Ludovico Colonna took his body to Pope Martin, who ordered it to be buried in unconsecrated ground outside of the walls. Eight years after, Nicolò Fortebraccio recovered from Pope Eugenius IV. the remains of his relative, and deposited them in the church of the Franciscan convent of Perugia. Oddo Fortebraccio, son of Braccio, resigned the government of Perugia to the hands of the pope, in July, 1431; and two months afterwards he was made Duke of Montone. The history of Braccio's life forms an important part of the history of Italy during the fifteenth century, which was the last age of its tumultuous independence.

(Fabretti, Biografie dei Capitani venturieri dell' Umbria; Campanus, De Vita et Gestis Brachii; Lomonaco, Vite dei famosi Capitani d'Italia; Compagnoni, Storia della Marca; and the contemporary local chronicles, among whom must be cited the most genuine and the most learned, the epic of Città di Castello, a poem of one hundred and one chapters in terza rima, entitled L'Altro Marte, in which he narrates in chronological order the deeds of Braccio and of his contemporary Ficochinu. This curious poem was printed at Vicenza in 1489: it is now extremely rare.)

BRACHYPHYLLUM, a genus of fossil plants, supposed to belong to the Coniferae. One species, B. mammillare of Brongniart, occurs in the carbonaceous beds of the Bath oolite formation on the Yorkshire coast.

BRACHYPODIUM, a genus of grasses (Graminaceae, P. C.) belonging to the tribe Festucine of that order. It has unequal many-flowered glumes; the outer pales rounded on the back, sericeous on the margins, inner nerves slightly converging, not vanishing upwards; the inner pales fringed on the ridge with rigid setae; the styles terminal. Two of the species, B. syriacum and B. pinnatum, are British. This genus is distinguished from Triticum (wheat) by the unequal glumes alone.

(Babington, Manual of British Botany.)

BRADFORD CLAY, a thin, cold bed of pale-coloured clay which lies upon the Bath oolite, especially at Bradford in Wiltshire. It is said to be the barmy (a pale earth having a fungous, the Pear Eocenite (Apocrinus rotundus of Miller).

BREAK, or BREAK, in Machinery, a contrivance for retarding or arresting motion, by creating an amount of friction too great for the moving power to overcome. Brakes generally consist of blocks of wood so connected with a system of levers or screws that they may be pressed firmly against the periphery of a wheel mounted upon the member of the machine; but in the wheel of the machine, instead of a block of wood, a strap or belt of iron, of sufficient length to embrace one-half of the periphery of the brake-wheel, or a series of small blocks of wood attached to the concave surface of such a strap, is used. The brakes of carriages are worked by levers, and often consist of a block of wood or a strap, which, by being pressed against the brake-wheel, stops the carriage. The brakes of railroad wagons, if small, as in the case of contractor's earth-waggons, are generally worked by levers, and often consist of a block of wood or a strap, which, by being pressed against the brake-wheel, stops the carriage. The brakes of locomotive engines have been worked by steam; but they are not generally used, being deemed better to confine the brakes to the tender and a few carriages in each train. With a view to prevent accident by the continued motion of the hinder part of a train when the engine is stopped by an accident, brake-ladders have been devised, which would begin to act as soon as the buffers of two adjacent carriages were pressed together, and would arrest the revolution of the wheels with a force directly proportional to the amount of the accident. Thus, if the brakes were adopted, but of these and many other schemes for the prevention of accidents, it is doubtful whether the inconvenience under certain circumstances would not more than counterbalance the anticipated advantages.}

BRAHMAH, or Brahman, was born on the 18th (New Style) or 2nd (Old Style) of April, 1749, at Stainborough, in York-}
shire, where his father followed the occupation of a farmer. He was the eldest of five children, and was intended for his father's occupation; but he very early exhibited marks of mechanical talent, and being, at the age of sixteen, incapacitated for agricultural labour by lameness, he was apprenticed to a carpenter and joiner. He subsequently removed to London, where he worked for some time at the cabinet-making business, and became a most expert in the same business himself. His adoption of the profession of engineer or machinist appears to have arisen from his invention of some very important improvements in water-closets, in consequence of which he became a manufacturer of such articles. His next important mechanical invention was the ingenious lock still known by his name, and which, after a lapse of sixty years, during which time many new kinds of lock have been introduced, maintains its character as one of the most satisfactory locks in general use [P. C. S. C. S.] This invention was patented in 1784. Among the numerous other inventions of Brahms were improvements in water-cocks, pumps, and fire-engines, and the hydraulic press, a machine of immense utility, and in which he was the principal inventor of the hydrostatic paradox. This invaluable machine, of which a description and representation is given under HYDRAULICS, P. C., p. 364, was patented in 1796. The boundless power which it enables one man to exert renders it an invaluable agent in many manufacturing processes, one of which is described under BANANAS, P. C. S., p. 169. In the following year he patented the elegant and convenient beer-machine which is now so universally adopted in taverns for drawing brandy in the bar from barrels deposited in the cellar, by means of a force-pump. He was also the author of improvements in steam-engines, especially in boilers; in machinery for producing smooth and accurate surfaces on wood or metal; in paper-making machinery; in iron-rolling-mills; in the process, by which several bars, resembling steel pens, are cut out of one quill, and fixed in a holder for use; and in the construction of carriages. In 1806 he contrived an exceedingly ingenious mode of printing, which was shortly after-ward employed in the number of newspapers, by the introduction of which, during the issue of one-pound notes by the Bank of England, the labour of 100 clerks out of 120 was dispensed with. This machine consists of a number of dies or other forms, which, when the financial power is turned on the periphery of each, the whole being mounted upon one axle, but capable of turning independently of each other. By the action of mechanism which is incapable of error, the position of one wheel of the series is moved between each operation of type setting, and the result is that it will print a series of numbers in regular progression, without the possibility of twice producing the same number. In 1812
he patented a scheme for laying down large water-pipes through the principal streets of London, of sufficient strength to withstand great pressure, to be applied by force-pumps; his object being to lengthen and cheapen the sea-waters, by throwing water without the aid of a fire-engine, and also to supply a lifting power applicable to the raising of great weights, by forcing water or air into an apparatus consisting of various pipes and engines, which united nearly to form a telescope, and capable of being projected when necessary. He asserted his ability to make a series of five hundred such tubes, each five feet long, capable of sliding within each other, and of being extended in a few seconds, by the pressure of air, to the length of 2000 feet. He proposed to raise wrecks, to submerge trees in Holt Forest by his hydraulic press, on the 9th of December, 1814, in his sixty-sixth year. In the construction of some water-works at Norwich, Bramah acted with success in the department of the civil engineer. He also appeared as an author in a" Dissertation on the Construction of Locks," and a 'Letter to the Right Honourable Sir James Eyre, Lord Chief Justice of the Common Pleas, on the subject of the canal engines,' which was published in 1797, and is referred to under WATT, P. C., p. 141. A memoir, which gives a very pleasing account of his amiable private character, and of his energy and probity in business, was published in the 'New Monthly Magazine,' and the centre of the city was given to the streets of London. A memoir by Brown, M.D., and a biographical notice, chiefly derived from Dr. Brown's memoir, is given in Stuart's 'Anecdotes of Steam-engines,' pp. 400-404.

BRANCHIOSTOMA. The name given by Costa to the most anomalous of all living fishes, and indeed of all the Vertebrata. This extraordinary animal was first discovered on the coasts of Brazil, a single specimen having been sent to Pallas from the coast of Cornwall, during the latter part of the last century. The great naturalist of Russia described and figured it in his 'Spicilegia Zoologica,' under the name of Linnaeus lanceolatus, but declaring it to be a mollusk, though remarking, in his description of it, on the resemblance of some of its characters to those of a fish. It seems to have been lost sight of for more than half a century; and, with the exception of a brief reference in Stewart's 'Elements of Natural History,' we find no notice of it in any synonyms of animals. In 1834 it was rediscovered by Costa, on the Neapolitan shores, who described it in the 'Annuario Zoologico,' under the name of Branchiostoma labriform; and some years after, in his Fauna of Brazil, he gave a description of it, in which he first perceived that it was a fish, and not an invertebrate animal, and remarked its affinity to the Cyclostome fishes. In 1836 Mr. Yarrell gave an account of it in his 'History of British Fishes,' under the name of the Lancelet, Amphioxus lanceolatus. He had not then met with Costa's account of it. He figured and described it from a specimen found by Mr. Couch at Polperro in Cornwall, the first taken in that locality since its original discovery there. Mr. Yarrell gave the first correct notice of the chorda dorsalis and vertebral column. About the same time, singularly enough, considering how long it had escaped notice since the days of Pallas, it was taken by several naturalists on the coasts of Sweden. Sundevall and Loven found it in Bohuslan in 1834, but did not give it the name of Branchiostoma. Loven published a notice of it in the Berlin Proceedings for November, 1839, in which also is a communication on the same subject by Professor J. Müller. Rathke gave an account of it in his 'Beiträge zur Anatomie der Wirbeltiere.' J. Goodrich published an elaborate memoir on its anatomy in the 'Transactions of the Royal Society of Edinburgh' for 1841, being the result of his examination of two examples taken in the Irish Sea, by Professor E. Forbes, in 1837. In 1842 a memoir on Branchiostoma was published by Professors of the Royal Society of Berlin, by Professor J. Müller, and this paper, beautifully illustrated, appeared in the volume of Transactions of that Society published in 1844.

The great interest which attaches to this fish depends on the strangeness of its anatomical characters, the unexampled degradation of its organization among the Vertebrata, and the peculiar and important fact which it furnishes to the physiologists, of the similarity of the circulatory systems of the lowest. A vertebrated animal without a brain, a fish with the respiratory system of a mollusk, and the circulatory system almost of an Annelide, presents a combination of characters which excited the interest equally of the physiologist and the systematic naturalist. Scarcely any animal yet discovered is so likely to change received views of classification and relative order of characters as the Lancelet. As yet however it has attracted but little attention among the zoologists, and anatomists have hardly perceived its value. For these reasons we shall give a full account of what is now known respecting its external character, structure, and habits.

Description. The size of the Lancelet is about two inches in length. The height to the length being as 1:10, and the breadth to the length as 1:10. It is of a lanceolate form, tapering to each extremity, and riband-like. Anteriorly it terminates in a head scarcely distinguishable from the body, apparently pointed, but in reality rounded and convexal. The body seems to end in a rounded and somewhat spathulate rostrum, beneath which is the mouth, a longitudinal opening, fringed on each side by a row of long filaments, which can close in the same manner as the protective blades of a scythe. Along the back runs a continuous flise, which dilates near the anterior extremity on each side, so as to form a sort of caudal fin. Near the tail opens the vent, in front of which is a median slit continued to another opening, situated a little behind and to the side. The organs of the larynx and pharynx are presented as an outlet for the genital products. Continued from this forwards nearly to the mouth, are two strong lateral fold, mistaken by Pallas for the margins of a ventral disk, and hence leading him to consider the animal to be a Mollusk. The entire animal is transparent and of a silvery whiteness, its sides being marked by the indications of the lateral lachrymic muscles, which give it the aspect of a small sand-eel.

Organization. Skeleton. The osseous system consists of a chorda dorsalis tapering at both ends, and, strange to say, not presenting the slightest vestige of a cranium, and of the germs of superior and inferior inter-spiral bones and fin-rays in the most rudimentary state. The chorda dorsalis is represented from sixty to seventy vertebrae, which are also in a rudimentary state and little more than indicated. The 'chorda dorsalis,' to quote Mr. Goodrich, 'is formed externally of a fibrous sheath, and internally of an immense number of lamines, each of the same form and shape of a section of the column at the place where it is situated. When any portion of the column is removed, these plates may be pushed out from the tubular sheath, like a pile of coins. They have no great adhesion to one another, and, by the removal of the constituent mine, can be distinguished from the bladders, as if formed of two tough fibrous membranes pressed together.' Besides the skeleton of the nervous system, there is a hyoid apparatus, forming the armature of the mouth, and consisting of two sets of 17 articulated pieces, from each of which, except 2, a ray proceeds. These rays form the outer cirri. Müller takes a different view of this structure, maintaining that it corresponds neither to the jaw-bone nor to the hyoid apparatus in other animals, but is analogous to the carina-branchial ring of the mouth of the lampreys and the Myxinid fishes, a system peculiar to that family. There is also in the lancelet a series of fine, transparent, carina-branchial hair-like ribs, seventy to eighty on each side, forming a cage for the protection of the branchial cavity.

Nervous system. The column of nerves extends from the head along the length of the spine, but is not quite so sharp at the fore-end as behind. It presents no trace of a brain. From 55 to 60 nerves pass off from each side of it, which do not arise by double roots. A single branch of the nerves at the anterior extremity is given by Mr. Goodrich. Müller and Rathke have observed the existence of rudimentary eyes, consisting of a small black spot of pigment, but not furnished with any optical apparatus. No traces of organs of smelling or hearing have been met with.

Vascular system. The observations of Müller having been made on the living animal, he was enabled to pursue this part of its organization further than the other observers. According to him, the vessels are arranged in general arrangement with that of fishes, differing however in regard to the heart from that of all other vertebrate animals, and displaying a striking accordance with that in worms, for
the branchial canal, and the musculature is highly developed.

The Respiratory system consists of a series of lateral muscular bundles corresponding in number, size, and position to the vertebral of the chorda dorsalis, and bearing a general resemblance to the lateral muscles of the higher fishes. Müller classifies the muscles of the Lancelet under the heads of 1st, lateral muscles; 2nd, abdominal muscles; 3rd, muscles of the oral ring and tentacular; 4th, muscles of the ring between the oral cavity and branchial sac; and 6th, muscles of the branchial apparatus. The skin is tough, and scaleless.

Habits.—The Lancelet lives in sandy ground at a depth of between ten and twenty fathoms water. It probably buries itself in the sand. When taken, it swims rapidly with a snake-like motion, but after a time settles down, unless disturbed, lying flat on its side. It is very tenacious of life. We have had it for three hours in a watch-glass under the microscope, at the end of which time, when disturbed, it seemed as lively as at first. It dislikes the light. It can be handled without injury. Its food was found by Müller to be the intestinal canal of some of the specimens hatched from the eggs of infusorial animals. The Lancelet does not swallow but simply imbibes its food.

General Remarks.—Branchiostoma, says Müller, is evidently a protected animal, and its food consists of larval forms of different species of the Cyclostomata fishes, but not among them, being removed from them by distinctions which are greater than the differences between naked and fringed individuals.

Viewed as an entire animal, writes Mr. Good, the Lancelet is the most abstruse in the vertebrate sub-kingdom. It connects the Vertebrata not only to the Anamniote animals, but also, through the medium of certain asymmetrical Ascidians (the genus Poliama of Forbes and Goodfellow) to the Mollusca. We have only to suppose the Lancelet to have been developed from the dorsal aspect, the seat of its respiration to be transferred from its intestinal tube to a corresponding portion of its skin, and the latter to be developed into a pair of one or more of its anterior spinal nerves, and inferior branch of its second pair, to have a true Anamniote animal, with its peculiar circulation, respiration, generative organs, and nervous system, with other-asomphal ganglia and dorsal ganglionic recurrent nerves.

Taking all we know of the structure of this truly wonderful animal into consideration, we are inclined to regard it as the relic of some great order of fishes, which in their organization bore a closer resemblance to the vertebrated than to the reptiles, or have been transferred to the lower forms of Mollusca, and which became extinct in some former epoch of the world's geological history, and, from the unapproachable character of their bodies, and the absence of hard parts, have left not a wreck behind. The more so, the more are we convinced that there are no isolated organisms; that beings apparently anomalous are members of orders either partially known or for the most part extinct. Of all anomalous creatures the Branchiostoma is the most so, and it is much more consistent with the principles of scientific zoology to admit it as the type of a distinct order among
ashes than to attempt to place it among defined groups. The strange combination of characters which it presents—a vertebrated animal without a brain, having the respiratory apparatus of an Ascidian Mollusk, and a ciliated intestinal cavity—if it does almost "arrant its erection to the type of a clav of its own rank" is a classification: it is thus sufficient to constitute it the type of an order in the lowest of the vertebrate classes.

**BRASSES, MONUMENTAL.** By a "brass," as the term is commonly used, is meant a plate of brass which has been cast in one piece, and then subjected to a sort of "polishing" being laid in melted pitch and riveted through the stone. The effigy of a person deceased is usually engraved on the brass plate; there is frequently a canopy over the head, and there are often armures which the brasses are represented with, and generally with inscriptions, sometimes on labels, sometimes round the border of the slab, but mostly below the feet of the effigy.

These separate parts have been, in almost all cases, engraved on detached plates, each of which is inlaid in its own cavity of the stone. The engraved plates were not originally in the plain state in which they now appear, but were generally burnished and sometimes gilt, and the incised parts were filled with black or coloured resinous substances. The plates were secured to the effigy by means of a flat, square, polished piece of a dark colour, and thus became an appropriate background, giving distinctness and relief to the engraved brasses, and adding to the beauty of the figures and ornaments. Slabs with brasses are commonly laid in the pavement of churches or cathedrals with the figured brasses; and the art of making brass was not introduced into England till 1630, the plates are all of foreign manufacture, of the hard kind of brass formerly called "latten." The art of engraving on the plates was probably brought to England from Flanders and France, as well as the plates themselves; early brasses still exist in this country which are known to have been engraved by Flemish artists, and there are many fine brasses still remaining in the churches of Flandrel. Those of France were mostly destroyed during the Revolution, when they were converted into coin or cannon.

It is impossible to determine when monumental brasses were first introduced into England, most of the oldest specimens having doubtless been destroyed, but it was probably in the early part of the reign of Henry III. Brasses with dates as early as about 1240 are known to have been destroyed. Probably one of the earliest now remaining in England is that of Sir Roger de Trumpton, at Trumpton, in the county of Cambridge, who died in 1280. During the fourteenth century monumental brasses became more and more numerous; in the fifteenth century they were in still greater abundance; but towards the close of the sixteenth the number began to diminish, and in the reign of James I. the use almost entirely ceased. Of all the fifteenth century there is a very fine brass of Harnett, archbishop of York, who died in 1631: it is at Chigwell, in Essex. The number of brasses which now remain in England, though still considerable, is very small compared with what it has been. Many were destroyed when the monasteries were suppressed in the reign of Henry VIII.; many have been torn up, and sold as old metal; but the greatest destruction of them took place during the predominance of the Puritans, who regarded them as superstitious.

The effigy on a monumental brass is generally represented reclining on the back, with the hands on the breast placed palm to palm, in the attitude of prayer; and this form applies equally to men and women; but on the effigy of children it is extremely rare. The head usually rests on a cushion, which is sometimes supported by an angel on each side. Military noblemen are generally in full armour; ecclesiastics in the vestments peculiar to their orders; ladies have frequently a small dog lying at the feet. The canopies and other engraved architectural embellishments are frequently extremely elegant. The canopy is sometimes a pediment with pinnacles and finial; sometimes a foliated arch; and sometimes a foliated arch below a pediment. It is frequently supported on slender pillars. Occasionally armorial bearings are placed on the pillars and spandrels, of which a specimen is shown in the article Town, P. C., in the beautiful brass of Eleanor de Bohun, in Westminster. The effigy of Reginald Bray, son of Edward III. The shields of arms, devices, and peculiarities of costume, appropriate each brass to its period in a remarkable manner. Each period has also a form of alphabetic character almost peculiar to itself, which, in the early brasses, is adhered to with singular uniformity. Some inscriptions in the Gothic letters are very handsome. Roman letters are rarely used before the reign of Henry VIII., and are generally inelegant enough. The Gothic forms continued to be used occasionally till a late period. Most of the early ones of the French inscription, and were in use from 1350 to 1400. English inscriptions afterwards became more common, but Latin still continued to be frequently used.

Monumental brasses in England have been most abundant in the eastern counties, partly perhaps in consequence of the contiguity of those counties to the Continent, whence the use of brasses seems to have been introduced, and partly of the want of stone suitable for the effigy in relief, for which the brass has been substituted. The number of brasses in the north of England brasses are comparatively rare. None have been found in Scotland; and only two in Ireland, which are of late date, in Dublin cathedral.

Specimens of monumental brasses are easily obtained by the process called rubbing. Paper of moderate thickness, transparency, and softness, is laid upon the brass, and rubbed with a black or coloured material, which adheres to the paper where the brass is solid, leaving its original state where there are inscriptions or figures on which the paper does not rest. With a little care a perfect fac-simile may be obtained. Shoemakers' heel-ball, which is a composition of tallow, wax, and lamp-black, has hitherto been found most convenient as a rubber; the operation is clean and easy. Paper of suitable transparency, or of a thin sheet of lead with a soft slab is manufactured on purpose, as well as suitable heel-balls.

Another material for making rubbings has recently been invented, which is composed of a yellow metallic powder mixed with the elastic substance of which the rubber is composed, as the lamp-black is mixed with the tallow and wax. When the rubbing is made on a dark-coloured paper, a fac-simile is obtained not easily distinguishable from the original: the figure appears to be the brass itself, and the paper which represents the rubbing seems to be the stone slab in which the brass is imbedded.

The first collection of copies of brasses was made by Sir John Cullum, Cirentr Ormd, and the Rev. Thomas Cole, not by rubbing in the manner just described, but by a rude process resembling copper-plate printing, which was successively worked over by the pen, and cost much time and labour. The collection was sold for 43l. to the late Francis Douce, and was bequeathed by him to the British Museum, where it is now in the print-room. In 1840 the first number was published of 'A Series of Monumental Brasses, extending from the reign of Edward I. to that of Elizabeth; by J. G. and L. A. B. Walker.' Parts I. to XV. have been published. The selection of specimens is very judicious, the plates are exceedingly accurate, and the work is accompanied by explanatory letter-press.

(As described in the article, 'Brasses,' and as translated from the original in the Penny Magazine, Nos. 812 and 813.)

BRAY, Sir Richard, of Wotton-under-Edge, near Gloucester, son of Edward III. The seventh of his chapel at Westminster, was the second son of Sir Richard Bray, one of the privy council to Henry VI. All that has been ascertained of his personal history is that he was greatly attached to the study of architecture, and stood in high favour with Henry VII.; therefore that he should be employed by that king to design the sumptuous structure intended for his own mausoleum was almost matter of course. Nevertheless, Bray's claim to the honour of so great a work has been widely disputed. It is certain that he did not live to see the building greatly advanced, the first stone being laid on the 18th of January, 1502 ('by the hands of John Islip, abbot of Westminster, Sir Reginald Braie, R. of the Garter, and others'), and he dying on the 6th of August in the following year. It is about a year and a half afterwards prove nothing more than that he did not live to see his designs for the edifice fully realised, the fact of his assisting with the abbot in the ceremony of laying the first stone having been most eagerly insisted on by the architect or designer of the fabric, it being the most unlikely thing imaginable that he would have taken an active share in such a ceremony had the building been the work of a rival artist. Besides, that Bray possessed talents equal to the occasion, it is most likely that he would not have been engaged by those who would reduce his fame, that he erected the nave of that other singularly beautiful structure, St. George's Chapel at Windsor, commenced by EdwardIV. Sir Reginald's arms, crest, and device, R. B., and a nem.-BM, occur in
many places on the ceiling of that building, and in the south aisle there is a chapel still called after him, in which he was buried.

BREAD, BEER, AND ALE, ASSIZE OF. [As-

size, P. C.]

BREATH-WATER. [Plymouth, P. C.]

BREAST WHEEL. [Hydraulics, P. C., p. 384.]

BREECA. [Omphrythus Breeca and Caerens, P. C. S.]

BREVIA RIA ALARICIANUM is now the usual name of the code which was compiled at the command of Alaric, king of the Visigoths, from the Roman law and Roman jurisprudence. It was completed a.d. 506, in the second year of his reign. The code was confirmed by the nobles and bishops, and signed by Anianus, the referendarius of Alaric, a circumstance from which it is supposed that he had a hand in the compilation that was the compiler of it. The title Breviarius Alaricianum was only introduced in the sixteenth century; it was sometimes called Lex Romans, and sometimes Lex Theodosii, in respect of the most important part of its contents.

The contents of the Breviary are formed of abbreviations or compilations from the following sources:—1, Codex Theodosianus, 16 books; 2, Novellae of Theodosiius I., Valenti-
nianus II., Marcian, Majorian, Severus; 3, The Institutions of Galien; 4, The Perpetual Senate of Paulus; 5, Codex Gregorianus; 6, Codex Hermogenianus; 7, Puginianus, lib. 1, Responsorum. Accordingly the code was composed of Imperial Constitutions, or Laws, as they are properly termed in the terms of writings of Roman jurists, which in the Breviary are termed Jus.

This Code is of some value for the history of the Roman law, as it contains extracts from portions of the Roman law which are ready matter to jurists, and is a work of public use, and from the first five books of the Theodosian Code, which however, owing to recent discoveries, are less imperfect than they were. The discovery of the Institutions of Galien [Gaius, F. C.] has rendered that part of the Breviarium in which Galien is epitomized of little value. The lacunae in Galien cannot be filled up from the Epitome, because the compiler paid little attention to retaining the words of the original, but the Epi-
tome shows what matters were discussed in those parts of Galien which were omitted. The whole body of the Breviary is contained in the 'Jus Civile Antejustinianum,' Berlin, 1815.

BREXIA/CER, a natural order of plants belonging to Lindley's polycarpous group of monopetalous Exogens. This order contains at present but one genus, and was constituted by Lindley in the first edition of his 'Natural System of Plants.'

The following is his description of the order:—Calyx inferior, small, persistent, 5-parted, articulation imbricated; petals 5, hypogynous, imbricated in stamens; stamens 8, hypogynous, alternate with the petals, arising from a narrow cup, which is toothed between the petals; ovary superior, 5-celled, with numerous ovules attached in two rows to placenta in the axis; seeds small, stipitate; fruit dry, 5-celled, many seeded; seeds indefinite, attached to the axis with a double integument, the inner of which is membranous; no albumen; cotyledons ovate, oblate; rachide cylindrical, centri
tetal. The species are trees with nearly single trunks; the leaves are coriaceous, alternate, simple, not dotted, with deciduous minute stipules; the flowers are green in axillary umbels, surrounded by bracts on the outside.

Dr. Lindley remarks that the habit of Brexia is that of some plants of the grassaceous, especially of Theophraster, from which it differs in being polypetalous and the stamens being alternate with the petals. Its relations are also strong with Rhamnaceae and Celastraceae, but its stamens are hypogynous, and its seeds are as in those two, with some resemblance to Anacardium may be seen in the recent appearance of the young shoots and in its habit. It agrees with Pittosporaceae in its hypogynous de
definite stamens, its polypetalous fruit, and alternate undivided leaves. There are three species of Brexia, all of them ele
gent, but differing from each other in the general form of turfy loam and poat, and cuttings with their leaves not shortened strike readily in sand under a hand-glass in heat, or a leaf with a bud attached will grow. The leaves are covered with a redness which causes rain to run off them immediately, and thus induced Noronia to give these plants the name of Brexia, from Brexia (Breixi), which signifies 'a wetting.' In gardens they are commonly called Theophrastes, but they differ considerably from that genus. All the species are natives of Madagascar.
water than usual, was knitted in a 'pug-mill' to a stiffer consistence than ordinary, thereby rendering a shorter period for drying sufficient. The rate at which the bricks were made by this machine was stated to be from one to two thousand pieces per hour.

Mr. Marquis of Tweeddale's invention, which bears a considerable resemblance in principle to that of M. Terrasson, arose out of a wish on the part of that nobleman to aid in forwarding improvements in the draining of land for agricultural purposes by removing the surplus water from land by means of drains or conduits formed of tiles, and laid beneath the surface of the ground; and it was with the hope of enabling these tiles to be made quickly and cheaply that the machine in question was devised. In 1787, a model of it was exhibited, and the most material part of what degree this machine differs from that of M. Terrasson.

The clay, in the first place, is forced between two rollers placed half an inch apart, so as to crush any stones contained in it; and is then worked up to the proper consistence in a revolving cylinder. The clay passes between two cylinders, which give it the proper thickness for a tile, while two side pieces give the requisite width: it traverses an endless apron which carries it to a piece of apparatus where the long side of clay is bent to the requisite concave form, and where a descending wire cuts off, by separate movements and at successive instants, pieces of the proper length for tiles. The action of the machine is continuous; for the long ribbon of clay is bent to, on which they are moulded, and by modifying the adjustments of the apparatus, the pieces so cut off may have the proper form for draining-tiles, house-tiles, flat roofing-tiles, or bricks. One man and two boys, with the aid of this machine, can make in one day ten thousand brick-shaped boxes, at the expense of sixpence per box. The second stage consists of twenty thousand flat tiles for the draining-tiles to lie upon; and the tiles so made are said to be stronger, more impervious to water, and smoother than those made by hand.

From about the year 1840 to 1842 the suggested or patented improvements in brick-making were very numerous; but they do not call for lengthy description. In Mr. McNab's method there is a sliding-frame beneath the bottom of the mill, in which the clay is ground; and this frame contains for the clay on which they are moulded, and by modifying the adjustments of the apparatus, the pieces so cut off may have the proper form for draining-tiles, house-tiles, flat roofing-tiles, or bricks. One man and two boys, with the aid of this machine, can make in one day ten thousand brick-shaped boxes, at the expense of sixpence per box. The second stage consists of twenty thousand flat tiles for the draining-tiles to lie upon; and the tiles so made are said to be stronger, more impervious to water, and smoother than those made by hand.

Another method introduced about the same time is nearly on the principle of the above. It is usually defined to consist in the mode whereby a screw forces the clay out of the mould, and also in the way in which the wires descend to cut it into bricks. A method patented by Messrs. Cook and Cunningham is on a different principle to the above. It consists in a frame or slide containing two moulds, is applied to the side of the mill in which the clay is prepared. The clay is forced, by the rotation of arms within the mill, through an opening into a box; and a piston working in this box presses the clay into one of the moulds in the sliding frame. When one of the moulds has been thus filled, the frame moves forward, which brings the other mould under the box, while the first mould is carried over an empty movable mould placed on a table; a piston pressing the brick in the empty mould, and the mould thus set free returns to receive a fresh supply from the box. The mode is thus so far a continuous one—that while one mould is emptying its contents into the movable one, the other is receiving a fresh supply at the box; while a boy receives the moulded bricks from the movable mould as fast as they are deposited in it. Mr. White's patent, of the same year, related principally to an improvement in the mode of supplying the clay from the mill, in the way of a separator. Mr. Gibbs has proposed a method in which both the materials of the bricks and the mode of manufacture are taken into account. He proposes to use Merthyr sand or pulverized Merthyr sandstone, combined with London clay or piper's ashes. It was found that a mixture of the former was a good clay, as in the latter, the ash was a powerful object of manufacture. The mode of making bricks under the patent embraces two or three modifications, of which one consists in rolling the clay out into a sheet of uniform thickness, then cutting it by machine-worked wires or wires into brick-shaped pieces, and compressing these by a separate machine. An American method introduced more recently by Messrs. Beach and Lukens, seems to be founded mainly on the plan of Messrs. Heaton, but to contain a provision for transporting the bricks to any convenient spot by means of an endless belt.

Mr. Freson's method is one of making bricks, tiles, and small articles of earthenware, from earth or clay almost in a state of dryness. This subject is noticed in connection with some of the recent inventions relating to Mosaic Pavements.

A communication was made to the Surveyor, Engineer, and Architect, a year or two ago, concerning the use of floating bricks. The Romans were acquainted with the use of bricks which would float in water; and M. Fabbroini, in the year 1530, discovered the use of earth or clay for this purpose. It occurred near Castel del Prano in Sicily; and the earth consisted of silica, clay, magnesia, lime, iron, and water. Bricks made from it floated in water, conducted heat with extreme slowness, and could not be fused in an ordinary fire. It is proposed in the paper just alluded to, that bricks so formed would present many advantages on ship-board, in all erections connected with furnaces and fire-places; and also that a novel kind of ornamental pavilions or houses might be formed on lakes in pleasure-grounds; the base being a platform of durable wood, and the superstructure of these buoyant bricks. The weight of the bricks, made by any method, is an important matter in relation to the purpose for which they are intended. The Marquis of Tweeddale, in a letter to the Royal Institute of Civil Engineers, after the reading of a paper relating to bricks, several engineers objected to the use of bricks made wholly by machinery, on the ground that their extreme compactness made them heavier and more costly than those produced by the ordinary art. The Marquis, however, brought in use a contrivance something like that of the Marquis of Tweeddale, but where hand-power and slight pressure are substituted for machine-power and heavy pressure. The decision as to whether or not the use of machine-made bricks, will probably depend, as in most other cases, on the relative expense in comparison with the hand method; hitherto they have been rather too costly.

Brick-edges are of two classes, public and private. Public bridges may be built quite as cheaply as private ones, and yet be more convenient and economical for highways, although the principle of that distinction does not seem very clear. Every county bridge is a highway, inasmuch as it is a bridge over which a highway passes; it is therefore in that respect strictly a highway; so also is every other public bridge over which a highway passes. The usual distinction drawn between them is derived from the nature of the space over which the bridge gives a passage. A county bridge, or, in other words, a bridge which the county is bound to repair, is formed by a line that is a highway. But sometimes a river or water flowing in a channel more or less definite, whether such river or channel is occasionally dry or not. This is evidently a very loose definition, for it does not prescribe or define the nature of the space, it only avails to this; but it seems clear that a county bridge must pass over a water, as the county would certainly not be bound to repair a bridge erected across a ravine, or over an ancient road crossed by a new road, having no reference to water. A county bridge may be either a foot, horse, or carriage bridge. A private bridge is any bridge which does not answer the description of a county bridge or a public highway. It is subject to no other laws than the general laws of property.

The liability to repair and maintain both county and private bridges is thrown on the whole county, that is, highways on the inhabitants of the parish wherein such highways lie. Prima facie, therefore, by the common law the whole county is the county to which is chargeable the repair of any bridge erected within it; or that some person, individual or corporate, is liable to that expense. In the case of private individuals, such liability may depend either on tenure, that is, by reason that they and those whose estates they have in the lands or tenements are liable in respect thereof, or on prescription. In the case of cor-
porate bodies, on prescription only. With regard to corporate bodies, Lord Coke says, 'If a bishop or prior, &c. hath at or twice of alms repaired a bridge, it bindeth not (and yet is evidence against him, until he prove the contrary); but if in the service of the bishop, they and the brethren, or such Alms of alms, this shall bind to it.' (2 Inst. 700.) Any bridge answering the description given above of a county bridge may become a charge upon the county even though not under the control of the corporation, if it be built by the county or by a private individual: but not every bridge which answers the above definition is therefore chargeable to the county for repair, unless it be also used and useful to the public. The public use and benefit seem to be the criterion: and they and the corporation, or any sort, which is principally for his own benefit and only collaterally of benefit to others, he will be liable to the repair, and not the public: but where the public derive the principal benefit to, or over, and adjoining it, and that ground that it would greatly discourage public-spirited persons from erecting useful bridges if they were ever after to be burdened with the costs of repair. The county are even liable to the repair of a public bridge erected by commissions under an act of parliament, even though the commissioners are empowered to raise tolls in order to support it, or though other funds are provided for the repairs; unless there be a special provision for exempting them from the common law. For it is not the common use and liability of a county to repair a public bridge is so strong, that although it has been erected and constantly repaired by trustees under an act of parliament, and although there are funds for the repairs, the county are still liable to it. And where trustees are appointed to erect and build a bridge, where a culvert would have been sufficient, but a bridge was better for the public, it was held that the county could not refuse to repair such bridge on the ground that it was not absolutely necessary.

The first statute on this subject is the 29 Henry VIII. c. 6, called 'the Statute of Bridges.' This statute is merely in affirmance of the common law. In course of time, owing to the indistinctness of the principle on which public bridges were held to be chargeable to the county, it was considered expedient to pass an act to come to a clear up the doubts and difficulties arising from this principle. In order, therefore, to ascertain more clearly the description of bridges hereafter to be erected, which inhabitants of counties shall and may be bound or liable to repair and maintain, it is enacted by stat. 43 Geo. III. c. 69, § 5, that no bridge hereafter to be erected in any county at the expense of any individual or private person, body politic or corporate, shall be deemed to be a county bridge, and shall be chargeable to the county, unless such bridge be made to pass in a plain manner under the direction or to the satisfaction of the county surveyor, or person appointed by the justices of the peace at quarter-sessions to superintend and inspect the work. This is extended to bridges newly built, and not to those repaired or widened.

It was found in very early times that many practical difficulties arose from the indistinctness of the common law as to the precise limits of a bridge—that is to say, as to the precise point where it ceased to be a bridge and began to be a highway; and vice versa. This indistinctness gave rise to many disputes about the liability to repair, and it was found expedient to enact, by stat. 22 Henry VIII. c. 6, § 9, that such part and parcel of the highways as lie next adjoining to the ends of any bridge, or the whole of every such part or parcel of said lands by the space of 300 feet, be made, repaired, and amended as often as shall need require; and that the justices of the peace should act respecting the repairs of such highways as they were empowered to act respecting the bridges themselves. The effect of this statute was merely to limit or fix the length of road which the county was to repair at 300 feet. By the common law the county was bound to repair the roadway at the end of every county bridge, but the length of that road was precisely determined till the passing of the above statute.

But this liability of the county has been very much narrowed by the stat. 5 & 6 Will IV. c. 60, § 21 (the General Highway Act), which, with respect to bridges to be built after the 20th of March, 1850, have a bridge shall hereafter be built, which bridge shall be liable by law to be repaired by and at the expense of any county, or part of any county, then and in such case all highways lying within five miles of such bridge shall be from time to time repaired by the parish, person, or body politic or corporate, or trustees of a turnpike road, who were by law, before the erection of the said bridge, bound to repair the said highways: provided, nevertheless, that any such bridge shall not be warranted to convey any county or part of any county from repairing the walls, banks, or fences of the raised causeways and raised approaches to any such bridge or the land adarche to it.

Till late years no persons could be compelled to build or to contribute towards the building of new bridges, or even the maintenance of old bridges under their construction or even under the act of parliament; and even when the county was bound to repair a bridge, it was not therefore bound to widen it. Nor could the inhabitants of a county by their own authority change the location of a bridge. But by the stat. 14 Geo. IV. c. 33, § 1, Old Gaol Bridge in the county of Lancaster, quarter-sessions are enabled to compel the county to widen or change the situation of old bridges, or build new ones. (See also 54 Geo. III. c. 99, which extends some of the provisions of the above statute.

With respect to the appointment of surveyors of county bridges, their duties and powers, and the modes in which such powers are to be exercised, see stat. 22 Hen. VIII. c. 5, § 4; 48 Geo. III. c. 69 (coupled with stat. 6 & 7 Will IV. c. 60); 54 Geo. III. c. 99; 56 Geo. III. c. 143. The various provisions of these statutes are very numerous.

For the mode of taxing and collecting the moneys necessary for the repair of bridges and the highways at the end thereof, see stat. 22 Hen. VIII. c. 6; Act 1, c. 18, 12 Geo. II. c. 29; 52 Geo. III. c. 110; 56 Geo. III. c. 143.

In case of non-repair or nuisances, either to bridges or highways, the modes of prosecution are the same: namely, by indictment, or for minor offenders, a fine, &c. speaking, an action cannot be maintained against the county by an individual for the non-repair of a county bridge, unless in some cases of special damage accruing to such individual from the non-repair.

A criminal information is very rarely resorted to, and only in cases of either very aggravated neglect or where there seems to be little chance of obtaining justice by preferring an indictment.

The appointment of a public bridge for non-repairs, &c. may by common law be before the Queen's Bench or at the Assizes. By the stat. 22 Hen. VIII. c. 5, § 1, presentations may be made before the justices in general sessions, and they may proceed therein in the same manner as the judges of the Queen's Bench were in the habit of doing, or as it should seem by their directions to be necessary and convenient for the speedy amendment of such bridges. See also for minor regulations respecting presentations, 1 Anne, sess. 1, c. 18; 1 Geo. II. c. 12, and consequent.

The indictment of a county bridge is subject to the same rules as any other indictment. And though the whole county be liable to the repairs, any particular inhabitant of a county, or tenant of land charged to the repairs of a bridge, may be made defendant in the indictment for the non-repair of it, and, speaking, an action cannot be maintained against the court for the default of repairs, and shall be put to his remedy at law for a contribution from those who are bound to pay proportionable share in the charge.

The malicious destruction or damaging of public bridges is said to be punishable as a misdemeanour at common law, since it is a nuisance to all the king's subjects. By 7 & 8 Geo. IV. c. 50, § 13, it is enacted, 'that if any person shall unlawfully destroy, or be maliciously, or negligently, or by a lawful bridge, or do any injury with intent and so as thereby to render such bridge, or any part thereof, dangerous or impassable, every such offender shall be guilty of felony.

(For further information see Lord Coke's Second Inst.; Burn's Justice; Russell On Gates.)

BRIDGEWATER TREATISES, a series of works which were published in accordance with the last Will of the Revd. Wm. Hill, minister of Bredwardine Church, and Revd. Geo. Bridge, who died in February, 1829. The Will, dated February 25, 1825, directed certain trustees to invest in the public funds 6000L., which sum, with the dividends accruing thereon, was to be at the disposal of the President, for the encouragement of learning. The trustees, being unable to determine who should be the President, or persons nominated by him. The testator further directed, that the person or persons selected by the said President should be appointed to write, print, and publish 1000 copies of a work 'On the power, wisdom, and goodness of God, as manifested in the creation; illustrating such work
by all reasonable arguments, as, for instance, the variety and formation of God's creatures in the animal, vegetable, and mineral kingdoms; the effect of digestion, and thereby of continued reproduction, on the species of animal life; and, lastly, the infinite variety of other arguments; as also by discoveries antient and modern, in arts, sciences, and the whole extent of literature. He also desired that the profits arising from the sale of the works so published should be paid to the authors of the works published.

The then President of the Royal Society, Davies Gilbert, requested the assistance of the Archbishop of Canterbury and of the Bishop of London, in determining on the best mode of carrying their request to the sovereign. After due consultation with his advice, he appointed eight gentlemen to write separate treatises on the different branches of the subject, which have been published, and are as follows:

5. By Prof. Dr. C. Wilby. 'Chemistry and Physiology, considered with reference to Natural Theology,' 2 vols. 8vo., London, 1840.

The Earl of Bridgewater also left upwards of 12,000l. to the British Museum, the annual income arising from which he directed to be employed in the purchase of manuscripts, and in taking the care of them for the use of the public.

In 1815, Matthew Boulton, the wealthiest man in Scotland, which, like the English brief, has a common root with the German brief, a letter or written paper. Its general character is that it contains permission or directions to make an inquiry regarding certain matters. It would appear that when the supreme civil court consisted of a committee of Parliament, permission to pursue before such a body was granted by brief from the Chapel Royal of Chancery, containing the questions on which a decision or answer was required. Of this character is the brief to the sheriff, which, in modern times is the inquest for service of heirs. This form is necessary for feudally investing an heir in his ancestor's landed property. If the ancestor was himself feudally invested, the heir sues out a brief, and is presented with the figures of the county where the lands lie, or if they lie in different counties, to the sheriff of Edinburgh, requiring him to enpanel a jury, and through their finding to return answer to certain questions. The brief and corresponding answer, or Retour, set forth the death of the person who was last invested in the property; the shape, whether as heir at law or by special provision, in which the heir succeeds, &c. This process is termed a Special Service. If the last proprietor was not feudally invested, the process is called a General Service, or a General special Service: the former, when the claimant is heir at law; the latter, when he claims under any particular provision. In both these kinds of service, the brief is the same as that in a special service, but the return leaves the particular questions unanswered. Where there is more than one person claiming the character of heir, separate briefs may be taken out, and a competition may take place before the jury, which may be, and generally is, carried into the Court of Session. The other briefs known in the law of Scotland are:—the brief of Tutory, by which an inquiry is made as to the person legally entitled to be tutor to a minor pupil, or, as it is termed in England, an infant; the briefs of Idiocy and Fruiriti, by which inquiry is made as to the quality of land, and of the income derived from the same, and medically deprived of the management of his affairs; the brief of Torace, for assigning the portion of the deceased husband's property, which is to be the widow's terce; the brief of Divorce, for settling the claim of heir's portioners; and the briefs of Lining and of Forfetment, for settling disputed boundaries.

BRIGGS, HENRY PERRONET, R.A. This distinguished painter, both in history and portrait, died in London, in January, 1844, aged fifty-one. He was of Norfolk family, and was the son of the painter. He commenced his career as a portraiture painter, and was an exhibitor on the books of the Royal Academy in 1814. In 1818 he exhibited a picture of 'Lord Wake of Cottingham setting fire to his castle, to prevent a visit from King Henry VIII.' He was afterwards employed to carry out the portrait of his patron, but in 1824 he exhibited a subject from Boccaccio (Gior. viii. Nov. 2), representing Calandrino, a Florentine painter, thinking he had found the Eletropia, and thereby become invisible, jelted out of a house by the sovereign and Buffalchino. These were followed by others of a higher class, as Orsello relating his adventures to Desdemona; the first interview between the Spaniards and the Peruvians; and George III. on board the Queen Charlotte, presenting a sword to Earl Howe, after the victory of the 1st of June, 1794. The last picture was presented in 1825 by the British Institution to Greenwich Hospital. In 1831 he exhibited a large picture of theuentes Britons instructed by the Romans in the Mechanical Arts, for the Mechanics' Institute at Hull. He was elected an Academician in the following year, from which time he was nearly exclusively employed in portrait-painting. His portraits are very effective as regards colour; but the colouring is rather conventional, and the features are not sufficiently modelled. His botanical drawings are also the following well-known persons:—Sir S. Meyrick, Baron Alderson, Sir Fowell Buxton, Rev. Sidney Smith, Mrs. Ojle, Mrs. Siddons, Charles Kemble, Duke of Wellington, and many others.

BRILL, PAUL. This celebrated landscape painter, was the younger brother and pupil of Matthew Brill, whom he greatly surpassed. He was born at Antwerp, according to Van Mander, in 1566, and received his first instruction from D. Wreteman; but having heard of the success of his brother at Rome, who was in great esteem there as a landscape painter during the pontificate of Gregory XIII., Paul joined him at Rome, and soon became not only a sharer of his brother's prosperity, but acquired a much greater reputation than he. He married a beautiful girl at that time Paul pursued an unrivalled career at Rome. No Italian had up to this period turned his attention exclusively to landscape with success, and Paul's ability was the more valued. He executed several large landscapes in oil, in the apartments of the Pope and other dignitaries of the church; in many cases, views of the villas or summer residences of his employers, all painted from nature, views, no doubt, in their town residences, as well executed, calculated to afford the highest gratification. He painted several celebrated pictures at a moderate price, in fresco, and of very large dimensions. In many of his works he introduced figures from the stories of ancient mythology, and Annibal Carracci is said to have sometimes painted subjects similar to his. Paul's works are often on copper, which are very highly finished; the foregrounds are fresh and bold, and the distances are well managed. His masterpiece was considered a large landscape in fresco, in the Sala Clementina in the Vatican, painted in 1602 for Clement VIII., and representing the triumphs of St. Clement: it was sixty-eight feet long and of considerable height. Paul died at Rome in 1622: his age and death are differently given by Ballinucci, who says he died in 1626, aged 72. Several of Paul's brilliant pictures have been engraved, and he executed a fewetchings himself. There is a print of him by De Jode after a portrait by Vandyck.

(Mautish, Het Leven der Schilders, &c.)

MITTISH. SHUL. IZIS (C. S.)

BRITISH HUSBANDRY. (HUSBANDRY, P. C.)

BRIZA, a genus of grasses (Graminaceae, P. C.) belonging to the tribe Festucineae, of that order. It has nearly equal, broad, fibrous glumes; 3-8 flowers densely infested in a short disconical cyme; the lower lemma heart-shaped, obtuse, rounded on the back, unarmed; the glumes and palea membranous with a sericeous margin; terminal styles. Two species of this grass are natives of Great Britain, the B. minor and B. major. They are known by the common name of Milhoppers. The stamens are usually in clusters of 3-8 flowers; the dense clusters of flowers are hung upon the ends of a very delicate filamentous peduncle, forming an elegant pendant which sways with the slightest breath of air, hence the name making-grass. It is a pretty grass in pictures, but do not yield much nutriment for animals, which feed upon it.

(Babington, Manual of Botany.)
BROZIO, FRANCESCO, a distinguished Bolognian painter, and one of the best of the scholars of the Carracci, was born at Bologna in 1674. He was a journeyman shoemaker until his twentieth year, when by the permission of his uncle, he was allowed to learn painting under Passerotti. He however soon made sufficient progress to perceive that the school of Ludovico Carracci was a surer road to success than the path of Passerotti, and he accordingly left the latter school, and in the school of the Carracci he became a favourite of both Ludovico and Agostino, for he devoted himself to engraving as well as painting. In painting also, Brozio did not, as is too often the case, restrict his studies to the human figure and its disposition, but he dissected the head, and by the aid of the form, perspective, architecture, and landscape. He was superior in these accessory parts of painting to all his Bolognese contemporaries, and, says Lanzi, was, with the exception of himself, the most able man in the school of the Carracci. His masterpiece is the Coronation of an image of the Virgin in the church of San Petronio. He died in 1623, aged 49. His son Filippo Brozio, and Domenico degli Ambrogio, called Menichino del Brolio, were his principal scholars, and were both very able painters.

Gandellini describes many prints by Brozio after the Carracci, Correggio, and others; 31 are noticed by Bartisch in the ‘Pezzato-graveur’. They are executed in the style of Agostino Carracci, and are sought after by many of the latter collectors. Brozio is better known for his prints than for his pictures.

MALVASIA, Felizit Pitture; Gandellini, Notizie loricelle degli Insiatruzioni, &c.; Lenz, Storia Pittorica, &c.; and VIRGILIO, originally the servant of Ben Jonson, gained a well-merited reputation as a comic dramatist. Of his life hardly any particulars are known; and it is only by inference that he is set down as having died in 1652. His extant comedies are fifteen. The earliest of these, ‘The Northern Lass,’ was printed in 1593. Five others appeared in one volume, in 1633; and five more in a second volume, published in 1693. His ‘Jovial Crew, or the Merry Beggars,’ has a place in the tenth volume of Dodge’s ‘Old Plays,’ and a second of the others are now known to be of dramatic composition in the school of Brome’s old master. They possess, in particular, great force in the representation of character. Altogether he may fairly be ranked among the best of our old dramatists of the second class.

BROMLEY, WILLIAM, a distinguished line-engraver. He engraved the ‘Allegorical Figures of Time’ in 1760, and was presented by his master with a London watch on his eighteenth birthday. He also engraved the ‘History of England’ after Stothard. He engraved several portraits after Sir T. Lawrence, including two of the Duke of Wellington, one on horseback, and Young Napoleon. He was engraved also the Woman taken in Adultery, after Lely. He was latterly almost exclusively engaged by the Trustees of the British Museum, especially in engraving the Ear Marbles from drawings made by the late H. Corbould. Bromley survived his son John Bromley, likewise an eminent engraver, and both are the last of a line of eminent print-engravers whose name has been for many years an associate engraver of the Royal Academy of London, and a member of the Academy of St. Liz. at Rome.

John Bromley was born in Chelsea in 1795. He followed his father’s profession, but he chose a different branch of it: his works are in mezzotint, in which line he had his superiors. He died in 1839, aged only 44, leaving a wife and a large family to lament his loss.

A Duc. and Generals’ Pick-Me-Up is the following:—The Trial of Lord William Russell, after Sir G. Hayter; Lady Grey refusing the Crown, after G. R. Leslie, R.A.; the Monks preaching at Seville, after J. Lewis; the Duke of Wellington, after G. Kneller; R.A.; the Trial of Queen Caroline, after Sir G. Hayter; and the Reform Banquet, after B. R. Haydon.

(‘Art-Union Journal, June, 1839; December, 1842.)

BROMUS (Bromus-grass, P. C.)

BRONCHOTOMY. (Trachyotom, P. C.)

BRÖNDSTED, PETER OLUF, a distinguished Danish archaeologist, was born on the 17th of November, 1873, at Hornema in Jutland, where his father was pastor. He studied at Copenhagen, and in 1896 he accompanied his friend Koes to Paris. After a stay of two years in the capital, both friends went to Italy. In 1816 a party consisting of Bröndsted himself, Koes, the architect Haller von Hel-

Bronome, mostly in the form of hydrobromate of magnesia, having been found in sea-water, and in many saline springs, such as that of Epsom, and that of Pittville, Cheltenham, and other places, and containing the salts of bromine, the per- cent Drottwich, either alone or associated with iodine, partic- ularly those of Kreznusch in Rhenish Prussia, it was inferred that it would prove useful in the treatment of scrofulous diseases. It is not, however, of much service in diseases with excess of potassa, in dilute liquid potash. It is in this latter way that it has proved most useful. It has also been used in baths, and likewise as an ointment.

The fact that many enlarged glands have lessened on its employment, led Dr. Willis to surmise that it would prove beneficial in enlargements of the spleen. He is su- guine of good results, but the number of cases in which it has been used is insufficient to warrant any general conclusions; and it is the great external or nostril person who is chiefly im- paired, either from a long residence in hot coun- ties or from having long suffered from agues, little can be expected from any agent. (Dr. Robert Williaus, Elements of Medicine, 1, p. 533.)

A bromide of iron has been formed, which is worthy of attention, as well as a bromide of mercury: there is likewise a bi-bromide of mercury.
BRONZINO, ANGELO, a celebrated Italian historical and portrait painter, was born at Montecelli, near Florence, in 1501 or 1502. He was the scholar of Pontormo, and the friends of Vasari, and like him an enthusiastic admirer of Michelangelo. Though Bronzino was not himself one of the gross anatomical marmesters with which Florence abounded in the latter part of his own life, he was one of the most influential causes of the predominance of the anatomical school, for by his own boundless admiration of Michelangelo, he set an example to the younger artists less able to discriminate the good from the bad in Michelangelo's style, and they of course appropriated what was most obvious to their senses, of features. A pupil of Filippo Alboni, the nephew and favourite pupil of Bronzino, was one of the most uncomprehending leaders of this school.

Bronzino painted in fresco and in oil; and executed many altar-pieces and other smaller easel pictures, which are scattered over the whole Italian peninsula. Besides, he was a good designer of medals, and his son Cristoforo Allori frequented adopted the surname of Bronzino, and it is a name often applied to them in catalogues.

(Vasari, *Vite de Pittori, &c.; Lanzi, *Storia Pittorica, &c."

BRORA COAL. Beds of very poor coal, lying in the midst of the oolitic deposits in the district of Brora in North Scotland and near Scarborough in Yorkshire, are thus termed. The coal is perhaps composed principally of Equiseta.

BROWN, THOMAS, better known by the familiar name of 'Tom Brown,' was born in Shropshire, in the year 1863. At the age of fifteen he was appointed a scholar of Christ Church, Oxford; but he left the university in disgrace without taking a degree, and, going to London, became a Grub-street writer.

The most respectable part of his career was his holding for a short time the mastership of the free school at Kingston-upon-Thames. Among the characters who composed the list of authors and "The immortal Brown," but more frequently designated by the familiar sobriquet of 'Capability Brown,' who was originally a kitchen-gardener, raised himself to be the eminent landscape-gardener of his day, and 'improver of grounds,' as to whom was considered the oracle of taste; and he also acquired no small degree of reputation by his skill in architecture. He was born at Kirkdale in Northumberland, in 1715, and in the early part of his life was in the service of Lord Cobham as gardener in the district of the person, and was noticed by the master of Stowe. After which he was similarly engaged by other persons of distinction, but of his rise until he formally established himself professionally as an artist-gardener, we have no account. His personal history is a scanty but an enviable one; he not only realized a handsome fortune, but he graced his acquired station of gentleman by the manners and feelings of one. After having arrived at the dignity of high sheriff for the county of Huntington, which office he filled in 1770, he was created a baronet in 1778; and died in 1783. One of his sons, the Earl of Donegall; made additions at Burleigh, for the Earl of Exeter; additions at Prior Park near Bath, 1765; the picture-gallery at Comber; considerable alterations at Trentham (now superseded by the present mansion), for the Earl of Shrewsbury; and the Earl of Donegall; made additions at Burleigh, for the Earl of Exeter; additions at Prior Park near Bath, 1765; the picture-gallery at Comber; considerable alterations at Trentham (now superseded by the present mansion), for the Earl of Shrewsbury; and the Earl of Redgrave; additions at Nuneaton, and the house at Claremont, now occupied by Queen Victoria. This last might be considerably extended, for it happens very...
singlyard that we possess a fuller and more authentic catalogue of Brown's architectural labours than of those of any one else in that profession; we shall however merely add that he designed several of the buildings in the gardens at Stowe.

(Repton On Gardening, by London.)

BROWN, DR. JOHN, an unfortunate man of letters, was born in 1715, at Rothbury, in Northumberland, where his father was curate. He studied at St. John's College, Cambridge, and took his degree with reputation: after which he resided for some years at Carlisle on a minor canonship and lecturership, and distinguished himself by acting bravely in the controversy in the relative of successively held and resigned several livings in the church. Of these one at least was procured through the influence of Warburton; a patron however whose letters show he has treated with little tenderness. Brown's temper was naturally tender in next to mental derangement. In 1766 the reputation with which his writings had obtained gained for him an invitation from the Empress of Russia to visit St. Petersburg, and assist in organising a scheme for public education. Ill health compelled him to decline the engagement. Other vexations preyed upon his spirit; and in September of the same year, seized with a fit of insanity, he cut his throat. Brown's works were both numerous and diversified, in verse as in prose. It was evidently one of the first steps of his vapour, was entrusted to Warburton to his editions of Pope's works. His tragedy of 'Barbara's, brought upon the stage in 1756, was highly successful for a time in spite of its extravagance and feebleness, and has been reprinted in several collections. It is said that 'Athelstan,' was not so fortunate. His principal prose writings were the following:—

"Essays on the Characteristics of Lord Shaftesbury," 1751; 'An Estimate of the Manners and Principles of the Times,' 1765, 2 vols. 8vo., a work which went through seven editions before the end of the next year, and received, a broad as well as at home, an attention which it owed to its severity of uncanonical version on national vices rather than to its merits as a philosophical speculation; an 'Additional Dialogue' of the Duke of Devonshire, 1744, another "Essay" on the "defence of the political character and conduct of Lord Chatham;" and a 'Disquisition on the Rise, Union, and Power, the Progressions, Separations, and Corruptions of Poetry and Music,' 1763, a treatise of considerable ingenuity.

All his works are enumerated in the long article under his name in the 'Biographia Britannica.'

BROWNE, WILLIAM, one of our minor English poets, was born in 1590, of a good family, at Tavistock in Devonshire, son of Sir Edward Browne, Excitor College, Cambridge, but left the university without a degree, and went to London, where he entered at the Inner Temple. In 1624 he returned to his college, and acted as private tutor to Robert Dormer, afterwards Earl of Caernarvon; and the degree of M.A. was conferred upon him by the university. Afterwards he became the joint owner of the Earl of Pembroke's library; and it is said by Anthony Wood that he was able to amass money enough to purchase an estate. The time of his death is uncertain; but it may have happened in 1645. But perhaps, as Mr. Burke remarks, his "Elogues;" a long series entitled 'Britannia's Pastoral,' a shorter entitled 'The Shepherd's Pipe.' In the narration of events, and in the delineation of characters or passions, he is feeble, confused, and tedious, especially in his more elaborate series of pastoral. But his poetry abounds in beautiful landscapes, painted with much delicacy of feeling and not without frequent richness of fancy. In 1772 there was published a complete edition of his poems, in three volumes, 12mo., which contained his 'Inigo;' a poem of some merit, printed in 1644 and 1646. He was mentioned several times by Barthelemonus Facius, 'De Viris Illustr.,' Florence, 1745; and Rathgeber, 'Annals of Painting, &c., in the Netherlands,' p. 105, enumerates twenty-nine works attributed to him. He is styled \textit{auctor terra}, from his book, 'Britannia,' and \textit{auctor terrae} from his book, 'Britannia.'

BRUCE, a genus of plants named in honour of James Bruce, the celebrated traveller in Abyssinia, belonging to the natural order Rutaceae. It has the following characteristics:—Flowers monocious; calyx of two parts, unequal; petals 4, hardly equal the length of the calyx; stamens 4, inserted round about a 4-lobed gland-like central body; the pistilliferous flowers with four abortive stamens; ovaries 4, seated on a 4-lobed receptacle, each terminated by a single, acute, reflexed stigma; fruit a drupe, 1-seeded. The species are shrubs, with unequally pinnate leaves, 6 pairs of opposite, entire, or serrated leaflets, without dos.

BRUCE, Charles ("Braces ferruginea" of L'Héritier), Woodbine, has rare leaflets covered with rusty villi on the nerves beneath; racemes simple, spike-like. This plant is a native of Abyssinia, and is said to be a tonic and astringent, and to act favourably in dysentery. By some mirtakes it was at one time supposed to be the plant which yielded the true Angustura bark of the shops. By the substitution of the fake Angustura bark of the shops. By the substitution of the fake Angustura bark for the true Angustura, P.C.] fatal effects have been known to follow. At the time that the false Angustura bark was supposed to be the product of \textit{Braces ferruginea}, an alkaloid was discovered in it which had long been known as \textit{angusturin}. [Smith, F.C.] Supposed now however, that there can be little doubt about the Angustura bark of the shops is a species of \textit{Strychnos}. Of this subject Dr. Christison, in the last edition of his Dispersary, has the following remarks:—"The Angustura bark (\textit{Galpinia Cinapioides} in our country is said to be genuine, and, as far as he knows it, perfectly genuine. But on the Continent a most serious fraud has been often practised, by the substitution of a highly poisonous but long erroneously conceived to be that of the \textit{Braces ferruginea} species. In America it is not uncommon to find a species of \textit{Strychnos} presented externally a dirty greyish yellow ground with numerous irregular spots or tubercles of a lighter grey tint; which appearances are in the larger pieces displaced a patches, or entirely, by a uniform, loose, bright, natty-colored efflorescence. The speckled ground is most resembling to the smaller pieces of true Angustura, but are easily distinguished by their greater thickness, their firmer, less intense bitterness, without either aroma or pungency, and also, the reluctance among the kernels to have the fracture becoming bright red when touched with nitric acid. Another excellent character mentioned by the Colleges, but applicable only where dusty specks exist, is that such specks become deep bluish green with the same acid; which, on the other hand, will not alter the speck of genuine Angustura bark, which, if not similarly altered the spurious bark, where it is quite free of dusty efflorescence. Fatal accidents from the substitutes of the spurious for the true bark were at one time not uncommon on the Continent, in Austria they were so frequent, that upon one occasion the government ordered the whole Angustura bark in the empire to be destroyed. This adulteration has never been publicly noticed in Britain, and experienced wholesale and retail dealers, whom I have consulted, have here in London, were unaware of its existence. A few weeks ago, however, Dr. Moore Neligan of Dublin informed me that on inquiring for Angustura bark at an extant and respectable drug-warehouse in that city, he got the spurious bark; which proved to have been part of a considerable stock kept in the establishment, since at least the beginning of this century, but never previously displaced. From specimens I owe to the kindness of Dr. Neligan, there can be no doubt of the accuracy of his observation; so that druggists ought to be aware of the possible risk, even in this country, of so arising an error."
There are at Munich three admirable old pictures in the Pinakothek (Cabinet iii. Nos. 35, 36, 37), assigned in the catalogue to John Van Eyck, which a writer in the ‘Kunstblatt’ (1841, No. 5) has attributed to Roger van Bruges; there are three of celebrated compositions by Dusseldorf, which were removed in 1805 to Munich. Joseph and his son Frans, who had adopted engraving as his profession, remained thither at the same time, and in 1806 Frans BRUILLOT was appointed assistant keeper of the royal library. He took up the business of engraving and devoted himself entirely to the study of prints and the history of engraving, and in 1817 he published, at Munich, in 4to., a Dictionary of the Monograms, &c. of artists—Dictionnaire des Monogrammes, Chiffres, Lettres Initiales, &c., to which, in 1820, he commenced the publication, in the same form, of a supplementary work, entitled ‘Table Générale des Monogrammes, Chiffres,’ &c., but which was never completed. His great work did not appear until 1835. By this time, the whole of which time was exclusively devoted to it. He visited the principal collections of France, Germany, and Holland, to the same end, and his occupations as keeper of the prints of the king of Bavaria, to which post he had been appointed in 1812, were for some time a regular part of his work. The complete work was published in Munich in three volumes, in 1832, in 33-34, under the title ‘Dictionnaire des Monogrammes, Marques Figurées, Lettres Initiales, Noms Angélos, avec lesquels les Peintres, Démêilleurs, Gravure, et Sculpteurs ont désigné leurs Noms.’ It was a work of immense labour, is very accurate, and is incomparably the most perfect work of its kind. In vol. i., containing the monograms, there are 3902 articles; in vol. ii., containing the chifres and letters, there are 1818 articles; and the work contains also facsimiles, cut in wood, of all the marks and letters, treated of, amounting to many thousands. BRUILLOT did not long survive the publication of his work; he died of the cholera in 1836, at Munich.

BRUNONIA, a natural order of plants belonging to Leguminosae and comprised of composite Exogomes. This order was defined by Robert Brown, and has for its type a genus which was named after him. He placed it as a section of the natural order Goodeniaceae, but it is raised to the rank of a natural order by H. K. Brongniart and Lindley. It has an inferior calyx in 5 divisions, with four bracts at the base. The stamens are inserted on a monopetalous corolla, with a few stamens. The flower is anisodactylous, with a single stigma enclosed in a 5-valved calyx; a membranous fruit (a utricle) enclosed within the indurated tube of the calyx; a solitary erect seed without albumen; and is monoecious, with a minute inferior red stigma. This order has been placed with all of which there are two species. They are herbs, native of New Holland, having flowers of an azure blue, which are on scapes, collected in heads, and surrounded by elongated bracts. A close path by BRUNONIA in Goodeniaceae, Lindley thinks essentially from the order in the superior 1-celled ovary and capitulate flowers, thus approaching some species of Disoeae, but differing in that of an involucel, the erect red ovary, superior ovary, and hairy corolla. The fruit is an isochasium, in the formation of the corolla, in the remarkable joint or change of texture in the apex of its filaments, and in the structure of the ovary and seed. Brown remarks that in the opposite parietes of the ovary of Pappus, there are, it is true, a number of non-functional corolla, which are continued into the style where they become approximated and paralole. This structure, so nearly resembling that of Compositae, seems to strengthen the analytical argument in favour of the hypothesis advanced in the present paper of the compound nature of the plants in that order, and of its type in phanerogamous plants generally; BRUNONIA having an obvious and near affinity to Goodeniaceae, in the greatest part of whose genera the ovary has actually two cells, with one or an indefinite number of ovula in each; while in a few genera of the same order, as Dampiera, Dipsaces, and certain species of Scrophularia, it is equally reduced to one cell and a single ovulum.

(R. Brown, Trans. Ross. xlii. 132; Lindley, Natural System, 406.)

BRUSSA, BRUSA, or BRUSAS (pecies), a celebrated town in the ancient province of Bithynia, now Kgı-ılı, in Asia Minor, lies in 40° 11' N. lat., 29° 26' E. long., and is situated on the northern foot of the Bithynian Olympus, in a most picturesque and fertile country. BRUS indicates by a dedication of the temple of Mars and Minerva, to the Mysian Olympua, which is the same as the Bithynian: it must not be confounded with Prusa, the Prusis of Stephanus Byzantinus, formerly called Chus (Kirc, Strabo, p. 563, Cæs.), of which city Prusas ad Hyposym, two towns which were likewise situated in Bithynia. Strabo (p. 564) says that Prusias was founded by Prusias, who carried on war against Croesus, and his statement deserves more credit than that of Pliny (Hist. Nat., v. 92), who says that it was built by Hannibal, alluding to the time when he was staying at the court of Prusias, king of Bithynia. Strabo's account is also followed or confirmed by that of Stephanus Byzantinus (v. Poëde), who calls Prusa a small town. The town rose only to importance by its capture by the king of Macedon, the first of the anarchists, who, with the assistance of the Osmanlis, which took it by capitulation a few weeks before the death of his father, in A. H. 736 (A.D. 1326). Fruus surrendered after a blockade of ten years, effected by means of two castles which Osmanlı built in the immediate neighbourhood, and the castle of Bubanjik, is still standing. This event took place towards the end of the reign of the Greek emperor Andronicus II.

Prusa, or as we shall now write it, Brusa, became the residence of Orkhan, and this sultan, as well as Must, I., Bayzid I., and Mohammed I., and several Turkish princes were buried in the new capital. The count of Nevers, a French prince of royal blood, and many French nobles who were taken prisoners in the battle of Nicopolis, were confined here. The Turks, however, regarded the capture of the Turkish empire to the capture of Constantinople in 1453, though during the last twenty years previous to this event the sultans used to reside at Adrianople. During several centuries it was the principal seat of Turkish learning, and its divines were notorious for their prejudices and asceticism; but its inhabitants are now distinguished for their toleration and hospitality towards Europeans. The population is about 35,000; one quarter of the town is entirely covered by the Turkish mosques, and contains several very fine buildings, among which the great mosque is the most remarkable; in the mosque of Dave Monasteri, rather a small building, is the tomb of Sultan Orkhan. There is a considerable trade at Kusadasi, silk, saffron, Angora wool, and other products of the country, and its carpets are renowned all over Turkey. There are several permanent European residents, mostly agents of German and Italian merchants. The port of Brusa is at Misdile, at the mouth of the Dardanelles, and many of the envoys of Brusa baffle description, but the principal features of the town as well as the envoys are the hot springs. The chief source is about a mile and a half west of the town; it rises out of a calcareous tuff or tufa, and is in the formation of which is still going on in some places. Hamilton found the heat of the water to be 184 Fahrenheit; about a hundred yards farther west there is another spring, the temperature of which is 180 Fahrenheit; and a few more yards farther west are several more in the neighbourhood, in some of which there is a considerable escape of sulphured hydrogen gas. The water of the springs unites in a warm state of a temperature of 97 Fahrenheit, which is inhabited by the Melangiae hestes, a species of frequent occurrence in the rivers of Asia Minor, but which prefers warm water to cold. Baths have been built at the two principal sources, which are much frequented by the Turks, and are used by the men and women on alternate days. In later years these baths have been visited by European patients, mostly residents of Constantinople.
BRUSBORCH. [Roter Domeister, P. C. S.]

The fundamental characteristic of the whole group of brushes is the vast diversity of their forms and qualities, adapted for use with the most different, brushes may be here considered under a few well-defined classes, to one or the other of which every article of the brush kind may be assigned. The kinds, though different, may be very different kinds, is distinguished by an obvious character.

The first great distinction is that between what may be called simple brushes, which consist of a single bundle or tuft of bristles, hairs, or vegetable fibres, whether large or small, and tufts, or tangles, which consist of small bunches, or tufts, separately inserted in a stock, foundation, or handle, of wood or other material, so as to act in combination with each other, but to present a mass of hairs or fibres of less solidity, to have a projecting fin on each side of the bush, or of brushing surface. Of what we here term simple brushes, an illustration is afforded by the kind of small brush used by artists under the name of a pencil, whether of camel's hair, or any other hairs. This instrument consists of a small tuft or bundle of hairs, carefully laid with their taper ends all in one direction, and having the opposite or root ends bound round tightly with thread. In order the better to secure the cylindrical tuft of hair thus formed, and also to afford convenient means of holding it to a stock or handle for use, the tuft or pencil of hairs is passed through a quill tube of a slightly conical shape, which has been previously softened and enlarged by wetting; the points of the hairs being temporarily bound together and passed completely through the quill, from the root end, while the quill being narrower at the tuft end, being larger than the point end, remains firmly fixed in the smaller end of the quill, which, as it dries, contracts upon the hairs with considerable force. As the quill is considerably longer than the portion of tuft or pencil left in it, its larger end forms a tube or socket for the reception of the pencil-stick. When well made, the hairs of such a brush should, if wetted, adhere together and terminate in a fine point; but if these ends are not together, the hairs being too tightly compressed by the small end of the quill, they will nozzle to, and the pencil is rendered unfit for delicate work. Hair pencil of this kind are made of every variety of size, from the smallest pencil or crow quill to the largest quills of the goose, turkey, or swan; and as even the largest quills are not large enough for some kinds of brush or pencil, while in other cases quills are not sufficiently strong and durable, thin tubes are occasionally substituted for them, the handle or pencil-stick used in the latter case formed of the same kinds of pencil made of bristle, or of the harder kinds of hair, for oil-painting, are usually mounted with tin, and are known by the general name of tools. For some purposes tin-mounted tools are made flat instead of round, the hairs being glued on in a layer, and the tuft or card being the form. The larger kind of bristle tools are not inserted in tubes, but are bound round very tightly and tied to the end of a wooden stick or handle, which is cut into a forked shape, so as to have a projecting fin on each side of the bush of hairs. The tuft or pencil being laid in between these projecting pieces, the whole is very firmly and closely bound round with twine or thread, which is subsequently smeared over with glue, with which red-lead is occasionally mixed.

In all the cases above mentioned the brush may be said to be inserted in the handle. The next class of brushes to be mentioned comprise such as have the handle inserted in the tuft or bundle of bristles or hair. Among these are the large painting brushes used by house-painters to take the bristles of which are first tied or wrapped round, with the smaller end of the conical wooden handle in their centre. The brush is then placed upon a block of iron perforated with holes to receive the handle, with the points of the bristles uppermost, and the conical handle driven in with considerable force until the greater part of its length has passed through the bristles to form the handle, while the thicker end remains in the middle of the tied portion as a sort of core. Such brushes are made in hollow cylinders of bristles, although when new they appear solid, or nearly so; and, although they seem to be held together only by the quantity of string wrapped round them, they really owe their firmness to the compression resulting from being driven in; but once the wrapping is completed. Excepting in the peculiar mode of tightening the bush by the insertion of the handle, carpet-brooms and birch-brooms resemble, on a larger scale, this kind of brush, to which, to distinguish them from tools, the name of brush, with some prefix descriptive of size or quality, is especially applied.

Intermediate between what we have distinguished as simple and compound brushes are a kind used by brush-makers and stainers under the names of stock brushes, or whitewash and distemper brushes, which may be described as consisting of two, three, or more simple bristle brushes placed side by side, or, in some cases, two or more brushes being inserted separately in holes bored in a stock or back of wood or other materials, there are two principal classes, distinguished by the mode in which the knots are inserted and secured. The tools which receive the knots are, in both kinds, usually bored in a lathe contrived for the purpose, in which the mandril, or axis to which the boring tool is fixed, projects in a direct line from the operator, and forms a right angle with, instead of, as in the common lathe, lying parallel to, the front of the bench. The former practice, which is still occasionally resorted to in boring the beads or stocks of large brooms, was to bore the holes with a bit and brace, the stock being, during the operation, firmly secured in an apparatus attached to the bench. The holes bored in this manner are, however, very ill-proportioned, and although the bored holes may not be parallel with each other, they may all be at right angles with the surrounding surface of the stock. The mode of making and fixing the tufts or knots in the kind of brush the man of pan-work or set-work, is as follows:—In making these, the brushe-maker takes in his hand, and arranges by striking their ends on a board or piece of marble, usually termed a drawer, behind the other end of the bundle presents an angle of clearness with, for the sides of the bush or tuft which will just enter one of the holes in the stock. Grasping these firmly with the fingers near the end which has been struck even, he dips that end into a pan of melted pitch, which, when necessary, is tempered with tallow or oil, and then severs the superfusible pitch by passing the tuft across the edge of a metal scraper; an action which also tends, by momentarily opening or flattening the bundle of bristles, to make the pitch penetrate into the heart of the knot. He then takes a pair of strong tongs, called a fros (usually the tongs of the two or three inches in length of a weaver's warp-threads, which, being short, would be useless for any purpose in which more than a few inches of thread is required), and quickly and securely ties and binds it round the bundle of bristles, or laid across the edge of the pitch, after which it is inserted in its proper bale in the stock with a peculiar twisting or screwing motion, which, coupled with the almost instantaneous setting of the pitch, renders it firm and secure. In this way we manufacture brooms, bannister-brushes, hearth-brushes, and many other kinds of house-brush, and also many of the lighter kind of brushes, such as the dusting-brushes used for pictures and furniture, which are technically called setusters, to distinguish them from the house-painters' brushes above described.

In most of the brushes hitherto described the bristles are used of their full length; or, if not so, the points, or, to use the term employed in the trade, the flags of the bristles are clipped off. Such brushes are termed short-brushes, and in colouring, and foruting, the ends of the bristles and knots must be made short and cut at their ends to a square or even surface, and the root ends of the bristles must be brought to the surface as much as possible, instead of the flag or taper ends. Clothes-brushes and some other brushes of this character are sometimes or have been occasionally made by the process last described, which, for fine work, may be varied by the use of various kinds of cement in lieu of pitch; but by far the more usual and usual practice is to clips off the ends of the brush after the process of drawing, by which all kinds of brushes comprised in our remaining genus of compound brushes are massfactured.
BRUCE

245

The stock of a drawn brush is bored in a similar manner to that of a set brush, excepting that, to enable the operator to bore the holes with greater accuracy, both as to their relative position and the angle they may be required to make with the surface of the wire, a convenient provision is made to enable him to proceed the more rapidly with his work. The stock is, during the operation, attached by clamps to a ready-bored pattern of hard wood, the holes in which, though somewhat larger than those required in the stock, are arranged precisely in the desired manner. The axis of the holes is in an inclined position, with the required degree of obliquity. This pattern, however, is not used for boring the holes for knots inserted in an oblique position on bevels formed upon the edge of the brush, which is worked by the eye, and from the stocks of set brushes. After each knot-hole has been thus bored into the stock just as far as the knot is intended to go, and no farther, a smaller boring instrument, called a bore-through-bit, is fixed in the lathe, and with it a small hole is bored completely through the stock, in continuation of each knot-hole. The brush-maker then, instead of taking in his hand as many bristles as will fill the hole, takes about half that number, and passes a portion of their root ends, of a length somewhat exceeding the intended length or projection of the tuft, through the hole or loop of a fine and flexible wire, which, with the other hand, he has passed double through the stock from the small hole which penetrates it. Having done this, he gives a smart pull to the wire, the effect of which is to open the knot or tuft of bristles which will allow it to come, the knot itself being, at the same time, drawn into a hight or double, which enters the hole in the stock, and is drawn in until stopped by the end of the wire, or stock, the latter being the bore and commencement of the smaller hole produced by the bore-through-bit. Passing his wire, which is almost as pliable as thread, through the next hole, the workman applies another knot in like manner, and so on until a row is completed, when he cuts the ends of the whole row off with a pair of powerful shears, to which is attached by screws a gauge to regulate the precise length of tuft to be left. If the drawing has been skillfully performed, the shears will take off little or nothing but the root ends. If, after the last cut off from the flag ends are, in many cases, long enough to form a fresh series of knots. As these are inferior in strength to the knots formed of the root ends, they are either used for interior brushes, or are worked up in a row of knots just within the edge of the brush, where, having the heart or centre of the brush on one side, and the outermost row of knots on the other side, of root-ends, to protect them, they are somewhat shielded from wear. As the drawing-wires at the present time are perfectly white, they are very liable to injury, it is usual to cover them, even in the commoner kinds of brushes, with a thin piece of wood as a veneer. In scrupling-brushes, which are much exposed to moisture, the wood is shell, which resembles the ivory, and is of great assistance in protecting the hair from this precaution; but if the drawing has been properly performed, the knots will be so tightly secured in their holes as not to give way, even after the destruction of the wire, unless the brush be allowed to get too dry, so that both the stock and the bristles shrink. Drawn brushes comprise, together with many other varieties of brush, all kinds of scratching-brushes, shoe-brushes, clothes-brushes, and tooth and nail-brushes, although, from their small size and the greater neatness required in their workship, the latter form a distinct branch of the manufacture. As veneering would be a difficult operation to perform upon tooth-brushes, these and other small brushes mounted in bone or ivory are frequently drawn with silver wire, which is either left visible, or sunk in fine gold, and the latter is afterwards filled up with a hard red cement; but in the best sort a very ingenious process called tempering is substituted for the ordinary mode of drawing. In tempered work the dressing of the stock is most conveniently done by applying to the stock, but are formed laterally in its thickness, from the end or sides, in such a way that after the dressing, which is then performed with thread or silk instead of wire, is completed, all traces of the operation can be concealed by filling up a few minute holes in an un conspicuous part of the stock with small plugs of bone or ivory.

The operation of drawing, in the larger and coarser kinds of work, requires great strength of hand and arm, and is performed either by one of the preceding processes, or by having the stock held fast in a vice, with both the left hand they gather up and apply the bristles, and with the right hand, which is protected from injury by a leather shield, they work and pull the wire. Some workmen use no vice, but hold the brush between their body and the front of the bench, but this is a most injurious, and, for short brushes, also a very incorrect method. But for the finest kinds of brushes, in scratching, in washing and picking the bristles, and in various cases connected with the manufacture of fancy brushes, women are extensively employed; and as the manufacture is one usually conducted upon rather a small scale, so as to partake of the character of a domestician manufacture, it may be well adapted for the employment of females and children.

There are a few other kinds of brush, such as bottle-brushes, which consist of tufts fixed so as to radiate from a stem of wood, or sometimes from a stem of ivory, as shown in figure Ure, in his 'Dictionary of Arts.' p. 190, describes a new mode of fixing the knots or tufts of brushes in dovetailed grooves formed in the stock, which was the subject of a patent granted in 1800 to Mr. Mason; but as the plan has not, so he believes, realized any decided advantage, it does not claim further notice here. More recently a patent has been obtained by Mr. Hancock for the manufacture of flexible back brushes, in which the knots are attached to yielding backs of leather instead of wooden stocks, and for some purposes such brushes seem to possess considerable advantages over those of the common construction.

Of the materials employed in the brush manufacture the most important are various kinds of bristles, of which a very large quantity is imported from China, Russia, and Persia. The bristles are plucked from the animal they consist of various colours intermixed, but before use, and in some cases before importation, they are sorted by hand into the several varieties of colour termed in the trade black, white, and yellow, the former being the lightest of all; but, excepting in the case of illices, a bundle of any one of these kinds will be found to contain many shades or varieties of colour, which are carefully intermixed in the process of dressing whenever it is intended to use them together. In dressing, the bundle is usually opened out, and combed with an instrument resembling a wool-comb, and, when a further separation of tints is not intended, the darker and lighter bristles are distributed as equally as possible among each other by hand. The process is continued until those operations the root-ends are carefully kept together, and in the dressing the bristles are separated into lots according to their length. If intended for fancy purposes requiring great neatness, the dressed hairs are subjected to the process of picking, which is performed either by children, in which every hair that differs much in colour from the mass is picked out by hand. Some bristles are also scorched or bleached, by which process they may be rendered almost without blemish, and the consequent appearance of the hair is often produced by the insertion, in one brush, of knots of picked bristles of various colours; and it is a common practice to put white or yellow bristles at the outside of a brush intended for ||

The genus BRYUM belongs to the natural order of Mosses. It has a terminal footstalk; double peristome, one of 16 teeth, inner one of a membrane cut into equal segments with filiform processes often placed between them; the calyptra dissimilis. The species of this genus are
exceedingly numerous. They are found in great abundance in Great Britain. They are all very small, produce a large number of capsules, and are found growing in wet places. The flowers of larger plants to miniature. In B. palustris are found terminal capitular bodies which resemble what are called the anthers of B. Androgynum; but in B. palustris they are considered parchment, and arise not only from the main stems, but also from the lateral ramifications.

(Loowon, Encyclopaedia of Plants.)

BUCKLANDIA, a lilaceous (?) fossil plant from the Stonesfield oolite.

BUDDLEIA, a genus of plants named after Adam Buddle, a botanist of the time of Ray, who contributed to Ray's 'Synopsis,' and whose Herbarium is now in the British Museum. Buddle belongs to the natural order Scrophulariaceae. It has a campanulate 5-tubed calyx; tubular corolla with the limb 4-lobed, equal, spreading; 4-5 stamens, the anther divided into two parallel distinct cells; the stigma clavate, 2-lobed; the capsule crustaceous with a dissection formed from the infixed edges of the valves, inserted in the thick spongy placenta; the seeds angular; testa loose, membranous; albumen fleshy. The species are shrubs, with mostly quadrangular branches, opposite leaves; terminal, capitate, spicate or panicked, usually orange-coloured flowers.

B. globosa has branches clothed with hairy tomentum, as well as the leaves. The flowers lanceolate, acuminate, petiolate, crenate; the heads terminal, globose, pedunculate. This plant, now so common in our gardens, is a native of Cibit.

B. Americana, branches clothed with hairy tomentum, lanceolate, acuminate, narrow at the base, crenate, rather pilose above, but clothed with a yellowish tomentum beneath; spike panicked, flowers glomerate. It is a native of the mountains of Peru, and also of the West Indies. Brown says that it is used in Jamaica as an emollient. Its properties however are not active. There are about sixty species of Buddleia, all of which are worth cultivating on account of their showy blossoms. B. Neomedia, a native of the peninsula of India, is said to be one of the most beautiful plants of that country. The B. globosa will bear with a little care our winters, as well as the B. salicifolia. All the flowers are sweet-scented. They growbest in a light rich soil. Cuttings will strike readily under a hood-glass. Those of the stone species require heat.

(Loudon, Encyclopaedia of Plants; G. Don, Gardener's Dictionary.)

BUOY LIGHT is a flame producing a strong illumination, and is now the means extensively employed in lighting churches and other great buildings. Originally it was obtained from an oil-lamp, the flame from which was acted on by a current of oxygen gas; subsequently oil-gas was substituted for this; but now the gas used for most of the streets of towns is employed to produce the flame, and the brilliancy is increased by a current of atmospheric air ingeniously introduced. This is designated the Atmospheric Buoy Light, and it is the result of numerous experiments made by Mr. Goldsworthy Gurney, of Buoy in Cornwall, who is also the inventor of the oxy-hydrogen light which is used with the microscope of that name.

The apparatus being suspended from the ceiling, the gas, either as it comes from the street or purified by chemical processes, passes up a number of short tubes into concentric annular receivers, the upper surfaces of which are pierced on the whole of their circumference with small holes. On issuing from the perforations the gas is ignited, and thus the gases of the cylinders are burned in the air. The gas in between while between and round the exterior of the cylinders the atmospheric air rises from below to support the combustion: a hollow frustum of a cone, of glass, open at both extremities and having the form of a truncated pyramid, forms the above mentioned; its lower part resting on the base of the framework within which they are suspended, and its upper part approaching very near the bottom of the flame, so that the atmospheric air rising in the conical form between the upper part of the cylinder and the flame. The distance between the cone and the rings, and between the rings themselves, are regulated by experiment so that the quantity of air may suffice to bring the temperature of the gas to an exactness necessary air cannot be obtained from the charcoal from the flame, as nearly as possible at the moment that the latter issue from the perforations: the flame from each interior ring serves to augment the heat of that which is on the exterior of it, by which means an increased intensity of light in each is produced; and almost the whole of the light which emanates from the interior rings passes through the flame, which, in turn, into the apartment.

A cylindrical glass chimney rests at its lower extremity on the margin of a circular aperture in the middle of a circular disk of iron, from 18 inches to 2 feet in diameter, the under surface of which serves as a reflector. A machine of this kind supersedes the employment of many separate lamps; and, being placed at a considerable height from the floor, it is possible to apply above the glass chimney a piper, which, by adjusting the screws, will conceal the upper extremities of the flame; and thus the latter presents the appearance of a brilliant zone of white light, which is from three inches to six inches high, according to the position of the gas.

A machine of this kind supersedes the employment of many separate lamps; and, being placed at a considerable height from the floor, it is possible to apply above the glass chimney a piper, which, by adjusting the screws, will conceal the upper extremities of the flame; and thus the latter presents the appearance of a brilliant zone of white light, which is from three inches to six inches high, according to the position of the gas.

BUILDING, or the art of constructing edifices, is defined by the ancients as the art of doing, or containing several and different conceptions of architecture; but, without a previous explanation of the meaning of the term architecture, such a definition is imperfect, since, although building is necessarily included or involved in the consideration of all architectural works, many of the works produced by the architect and the architect's helpers would not be considered as architectural works. In the practice of civil architecture, the builder comes between the architect who designs the work and the artificers who execute it. In a large commercial point of view, between the party by whom the capital is provided on the one hand, and the merchants and manufacturers who provide the necessary materials, and the workmen whose offices it is to shape and unite them, on the other. For the temporary employment of his own capital and the exercise of his directing skill, he is usually remunerated by charging his employer for labour and materials at a higher rate than he has paid himself; and, for the mutual security of all parties, he generally works by contract, either undertaking to execute the building, with all contingent works, for a given gross sum, which is termed a lumping contract, or agreeing to perform the whole work at certain specified rates per yard, rod, foot, and as such, according to the nature of the work, the quantities being measured by the several ways of measuring.

An article upon the multifarious operations connected with building would not only require more space than is consistent with the plan of this work, but would also involve the repetition of matter contained in a preceding article. Such a general treatise is supplied in the long and elaborate article Building, in the new edition of the Encyclopædia Britannica, contributed by Mr. Hoekling; a treatise which may be consulted with advantage by those who wish to go very fully into the subject. Here we propose to do little more than give such an outline as may enable the reader to turn readily to those portions of the work in which the various branches of the general subject are treated of.

An abstract is given in the next article, to illustrate the present article. The subject of domestic architecture, which is it all-important for a builder to be well acquainted with, is treated at some length. From the last-mentioned article it will be evident that the attention of the builder should be directed rather to matters of utility and comfort than to such as relate to ornament; and the most beautiful walls that this world has seen, are those of the truest and most profound and religiously to cold winds. A good supply of water to the house, and sufficient fail to ensure perfect drainage, are essential; and as a general rule, the advantage of southern and western frontages should be secured as much as possible. The direction of the prevalent winds is a point to be carefully considered, in order that the openings of doors and windows may be so arranged as to avoid drafts and smoky chimneys, which are not unfrequently occasioned by want of due attention to the matter. [Smoke, P. C., 156.] Such points being duly considered, drawings of the intended building, showing not only its exterior form, but also its interior arrangements and the substance of its walls and partitions, as explained under Design, Architecture, and its parts, are necessary. It has been shown in which the actual construction commences by the preparation of a firm foundation for the structure, as described under Foundation, P. C., p. 383. The excavation formed for the foundation walls is about to the depth at which level must be produced by the removal of earth until an even surface is produced; the production of a level by filling up hollows with loose materials is extremely hazardous. For the mode of laying foundations under water see Cowperham, P. C., p. 410.

The articles Brickwork, P. C., p. 410, and Mortar, P. C., p. 419, contain information on the construction of brick walls, but the provisions of the new Metropolitan Buildings Act of 1875 require that such walls must be built of bricks, unless it is necessary to substitute for the directions given under Brickwork, relative to the thickness of walls, the following new regulations for the thickness of external and party walls of dwelling-houses. First-rate buildings, which are such as range from 70 to 85 feet in height, cover more than ten, and not more than fourteen squares, or areas of 100 superficial feet, or contain more than 700 square feet of the floor, are to have their external walls at least 17½ inches thick from the top of the footings of the foundation up to the under side of the floor next but three below the topmost floor, that is to say, in a seven-storey house, the full height of the basement floor, and the three floors above it. From the under side of the floor next below the topmost floor, a further height of three stories, the thickness is to be at least 17½ inches; and the remainder of the wall to the top at least 13 inches thick, in a house less than 100 feet long. In a house which is wider than 100 feet long, the party walls is precisely the same as that of the external walls; but in buildings exceeding 85 feet in height, covering more than fourteen squares, or containing more than seven stories (which buildings are considered as extra first-rate), the thickness of 21½ inches is to be carried up to the floor next but two below the topmost floor, and that of 17½ up from that point to the top of the building, in the external walls, and the party walls must be at least 21½ inches thick from the footing to the floor next but three below the topmost floor, 17½ inches from this point to the under side of the topmost floor, and 18 inches from the topmost floor to the top of the wall. Second-rate buildings, which are such as range from 52 to 70 feet in height, cover from six to ten squares, or contain from four to six stories, must have the external walls at least 17½ inches thick from the footing to the under side of the floor next but one below the topmost, and 18 inches above that point to the top. Third-rate buildings, or such as range from 38 to 52 feet in height, cover from three to four stories, or contain five stories, must have their external walls at least 17½ inches from the footing to the floor next but two below the topmost floor, and 18 inches thence to the top of the wall, and their party walls the same, excepting that from the topmost floor to the top of the wall, the thickness is not to be reduced to not less than 8½ inches. Fourth-rate buildings, or such as do not exceed 38 feet in height, do not cover more than four squares, or contain more than four stories, must have their external walls at least 13 inches thick from the footing to the under side of the floor next below the topmost, and at least 8½ inches thence to the top of the wall, while the party walls must be at least 15 inches up to the floor next but one below the topmost, and 8½ inches above that point. Thus a four-story house, if not more than 85 feet in height, or covering more than four squares, must have its external walls 13 inches thick for the full height of the basement story and the next story above it, while in the party walls the thickness is not to be reduced to less than 7 inches. Buildings of the second class are divided into four rates, according to their height; those exceeding 66 feet in height being deemed first-rate, those from 44 to 66 feet second-rate, those from 22 to 44 feet third-rate, and those not exceeding 22 feet fourth-rate. First-rate buildings of this class must have both the external and party walls at least 26 inches thick from the top of the footings to within 76 feet of the height of the topmost ceiling, 17½ inches thick from within 76 feet of the topmost ceiling, and 17½ inches above that point to the top of the wall if it be an external wall, though in the case of a party wall the thickness may be further reduced to 13 inches above the top of the floor next but one, or the second-rate must be, whether external or party walls, 21½ inches thick to within 58 feet of the topmost ceiling, 17½ inches to within 22 feet of the same, and 13 inches above that point. Those of the third-rate must have their external walls at least 28 feet of the topmost ceiling, and 13 inches above that point, and their party walls 13 inches thick above that point; the party walls being the same, excepting that above the level of the topmost ceiling they may be reduced to 8½ inches; and those of the fourth-rate must have their external walls 13 inches thick above that point, and the party walls of the same thickness to within 9 feet, and the party walls of the same thickness to within 16 feet of the topmost ceiling, the upper portion of the
wall, in each case, being at least 3½ inches thick. The substance of the trusses of the walls of buildings belonging to the third or public class is to be computed by reference to the rate of such buildings of either the first or second class as they may most nearly resemble, four inches being in every case added to the thickness directed for such first or second class. In the case of a small church or a large house, which may be placed in the middle of the street, the area is to be computed by reference to the house or building of the next larger class.

The Laing Act, Sir, provides, as the means of counteracting such advantages in the brickwork of the fingers, a flat piece of flag-stone in such a manner as to form a dipping-rose resembling that shown in Scaithorpe, Fig. 4, so that no water can escape until the wall is filled, and no air can pass the wall. This is, truly, the best method, and if dry is to allow it to pass under the edge of the dipping-rose.

As the erection proceeds, contrivances for supporting the workmen and materials are required, of which an account is given under Scaithorpe, P. C., p. 437. Under Watten, 248 P. C., p. 313, allusion is made to a very convenient apparatus invented by Dr. (there misprinted Mr.) Spurin, for lightening the labour of raising bricks and other materials to a second floor. In the basement story of a building, the partition wall as well as the external walls or part of it is generally formed wholly of brickwork, but in the upper stories they are generally of plaster and plasterer, on a framed and plastered foundation, or of what is technically called brick nogging; this does not prevent much timber being used for plaster and plasterer, but having the intermediate space between the timbers filled up with brickwork, thus forming a wall either 4½ or 5 inches thick, according to whether the exterior wall is 4½ or 5 inches thick.

The upright quarterings or timbers, the brickwork, being so close, should be strengthened or bonded further by the introduction of iron bars or rods, at intervals of not more than six courses, of horizontal iron bars called intees, or nogging-pieces, skew-called at each end to the quartering timbers, and thus, in the passage of half-brick, or 4½ inch, walls carefully built in cement, are strengthened with iron hooping, a plan which has the advantage of greater security from fire. Such partitions also check, more effectively than timber, the transmission of sound from one room to another. The joints of brickwork in internal walls, and in such external walls as are to be covered with plaster, stucco, or cement, are left rough, with the mortar projecting from the joints, because the inequality of surface thus produced admits greater ventilation of the walls than if all the mortar were made smooth. The beds of mortar between the bricks is not only injurious from the settlement thereby occasioned, but also because the compression of the mortar causes it to bulge out at the joints, and so to counteract the effect of drawing with the trowel. The mortar, instead of preserving the joints, absorbs both the moisture of the air and the rain which trickles down the wall, and when it freezes comes this absorbed moisture freezes and occasions the mortar to crumble away, thus involving the necessity of pointing, or filling in the joints with new mortar, to preserve the wall.

To do this, the old mortar must be scraped out to a depth of three-eighths of an inch, or further if needful, and the joints must be thoroughly cleansed and moistened before inserting the new mortar, which should be of the best quality. The heads and tails of the bricks are thus covered with a bed of good cement, and Forced ashes, which give it a blush tint, and renders it better to resist injury from weather. Cement is sometimes used for the purpose in lieu of mortar. If the work be required to be done in a narrow space, or between parallel ridge of fine white putty or mortar, made principally of bone-lime. In the application of this kind of pointing, which is termed buck-pointing, to an old wall it is usual to wash and colour the whole surface of the brickwork; and in narrow passages or walls of stone, a far better effect is produced if thin strips of red or blue mortar which should come in a line over each other, technically called the perpends, have been properly attended to, the misplaced joints may be filled up with brick-coloured putty, and the junctions made in the plain plaster. For mortar used in the setting, or internal plastering, of brick chimney flues is mixed with a little cow-dung, to prevent its peeling off from the heat. The top of a brick-wall, whenever it is not covered by the roof, must be protected by coping [Cowper, p. 501], which in single-brick walls is often formed simply
by a row of bricks set on edge in cement across the wall, and called a *bâche-course*, a name which is also given, with more propriety, to the projection of a row of lapper-tile. Bâche-Course, P. C., p. 450.] This kind of coping is very imperfect, because, as it has no projection or inclination, it does not tend to channel off rain, and may be washed off by waves, and hence the appearance and efficiency by laying underneath the bâche-course two double courses of plain tiles, with their joints broken, and their edges projecting about an inch and a half on each side of the wall, or by a similar application of paving-tiles, if the wall is of brick. The courses may be made of any width, and properly sloped or weathered and threated, is far better. For ornamental brickwork proper coping-bricks are made, which if well set in fine mortar or cement may be equal, if not preferable, to any other character. It may be remarked generally that brick walls often suffer injury in consequence of the insufficient projection of copings and cornices, which ought to throw off water as much as possible from the face of the wall.

The established mode of measuring brickwork is explained under *Brickwork, P. C.* Brick and tile paving, which are noticed under *Floor, P. C.*, are measured by the superficial yard of nine feet, and tiling, for which see *Roof, P. C.*, and *Tiles, P. C.*, p. 446, by the square of 100 superficial feet.

Of the use of stone in building some account has been given under *Masonry, P. C.*, p. 481; *Ashlar, P. C.*, p. 451; and *Rutified Work, P. C.*, p. 271. Rutified-work is more difficult and expensive than brick, and, above all, not equally durable, and, since there is great danger of trusting too much to the mortar. Unwrought stones, however irregular in shape, ought to be so laid together that the wall would stand if laid to a considerable height without mortar, but the joints should be so made as to be desirable to give the outside of a rubble wall as neat an appearance as possible; but care must be taken in doing so to bond the facing stones as thoroughly as possible with the centre of the wall, and not, for the sake of show, to expose the bed of the stone, or the flat surface formed by its sacrifice, in the face of the wall, as a stone so applied cannot be firmly bonded into the wall, and its flat surface is far more liable to injury from the action of the atmosphere than a surface cut at right angles to the flat. But it may be desirable to bond the wall by means of many stones extending partly through its thickness, alternately from each side, than to use a few thin, large, or stones reaching completely from face to face, and yet leave the greater part of the wall like two shells inclosing an irregular core of coarse rubble. Stone copings and some other kinds of stone-work are frequently cramped together with fastenings of iron or copper, run in with melted lead; but unless these metal fastenings, especially those which are wholly exposed to the effects of the atmosphere, are liable, from oxidation and the effect of changes of temperature, to produce much harm, and therefore it is better, if possible, to use tenons, dovels, joggles, or dovetails of stone or wood, protecting them also from the weather by means of building-up of roofing, as in the case of ornamental rustic-stones, is described under *Blackfriars Bridge, P. C.*, p. 485. The principal purposes for which stone is introduced in brick buildings are enumerated under *Masonry, P. C.*, to which we need only add that the setting of stone window and door sills is usually delayed as long as possible, to give the brickwork time to settle, because a very slight inequality in the settlement would cause them to break, being long and thin. The brittleness of stone, indeed, renders it necessary, with a plastered surface, to give it all possible of bearing, and very important to make the joints perfectly even. In the joining of columns, for example, the ends of the adjacent stones must not be worked hollow, with a view to be bedded directly into a bed of mortar, but, if so arranged, the best plan is to work them flat, and insert a thin sheet of lead between them, cut a little smaller than the column itself, thereby leaving a small open joint all round, to be filled up with fine putty. Stone walls are usually measured by the perch of 31 superficial feet, though this may be less, and a stone wall containing 314 cubic feet; but sometimes the rod is used as a measure, as in brickwork, assuming however a thickness of 18 inches instead of 13 inches, being 3d. in stone and earth. Houses built of flints, which can only be used to advantage in certain localities where that material abounds, necessarily depend much for the cohesion of their walls upon the strength of the mortar, and on the building of coursed work of brick or stone, and of quoins or angles of the same. When been well executed, the appearance of flint buildings is far from pleasing, but by little management of the contrast afforded by the white outside and black centre of the flints, may be made absolutely ornamental. Building with compressed earth, or building *en Pâé*, is a very old and simple and even elegantly managed, durable mode of building, which has been long and extensively practised in some parts of France, especially in the neighbourhood of Lyons, and has been adopted in this country not only in the construction of large rooms, but also in the constructing cabins with mud tempered with straw, and held together with wooden and timber framework, but also in lieu of regular brickwork. In vol. xxvii. of the Transactions of the Society of Arts, pp. 1797, is a minute description, illustrated by a plate of the apparatus employed in this improved mode of constructing this kind of work, invented by Mr. Robert Salmon, of Woburn. The foundations, and the walls to a short distance above the ground, are built of stone or brick, but all the upper part of the walls consists simply of earth, beaten or rammed into a compact mass between three and four feet thick, which is fastened in such a position that their inner surfaces correspond with the faces of the wall. The work proceeds in courses, and each course in portions of convenient length; the labourers underneath the course serve as a sort of dam by bolts that they may be readily separated from one another, and from the completed portion of wall, and put together again in the required position for forming another portion of wall. The walls were constructed with materials so small, that every portion may be very completely examined, and it is thrown in, a little is drawn away from the surface of the mould, and its place supplied by a facing composition, consisting of about one-fourth lime and three-fourths of the earth. For walling the doors and windows, the mortar, rather than the mortar, but allowed to dry and pulverize before it is rammed in this facing composition, which is applied about an inch thick, forms a cement-like face to the wall, which preserves the earth from the access of moisture. When made, this course of one course of earth has become hard before another is added to it, a little thick grout of lime and earth is added to facilitate the adhesion of the new and old work. Mr. Salmon observes that the earth for this work 'should be neither sand nor clay, but very gritty, 'to avoid the first, and to partake of both,' clay, he adds, being more durable, and much more compactible, as is also chalk or calcareous earth of any sort. Sand is also not proper, unless accompanied with some binding quality: the bolder and coarser the sort of earth the better. When used, it should retain no more moisture than just to make it adhere together under the pressure of the thumb and finger.' Earths containing a mixture of grit or fine gravel he considers generally the best. Bond-timbers, wall-plates, and all other pieces of wood inserted in the walls are, kept as thin as may be, to prevent the entrance of moisture in all cases, and the openings for windows may be conveniently formed by the insertion of temporary frames of stout planking, against which the earth is rammed as against the mould. In this description the reader is referred to *Building*. At Woburn, with labourers at 1s. 10d. per diem, Mr. Salmon found the expense of a 16-inch wall to be about 2s. 8d. per superficial yard if faced and finished on one side only, and 3s. 3d. per yard if faced and fastened on both sides; while the value of a superficial yard of brickwork, 14 inches thick, would have been more than 10s. at the same time and place.

The walls may be finished externally by limewashing, and, if intended to look very neat, wetting and rubbing the surface with a mixture of coarse sand, until it is smooth and even. A full account of the French mode of executing this kind of building is given in the sixteenth volume of the 'Dictionnaire Technologique' (Svo., Paris, 1829), art. 'Pâé, Pâé', and in a brief note in the *Dictionnaire de l'Industrie* (Svo., Paris, 1795), article 'Murs, Écluses, Économies,' are some remarks respecting the meaning of the term *Pâé*, or, as it is sometimes written, *Pâte*. If the projection of the roofs be sufficient, and other precautions are taken to keep the walls from being exposed to wind, this mode of construction of two or three stories in height, and they will prove very durable, many such buildings in France having stood more than a century without any symptom of decay. Respecting the means of preventing any kind of drawback, whether arising from the foundation or not, some information is given under *Asphalte, P. C.*, p. 144. Double walls, in which a space is left between the external brick or stone wall, and the lining of the room, of whatever kind it may be, are sometimes resorted to as a means of preventing the passage...
of dams, and a simple mode of producing the same effect, which answers well when great strength is not required, is accomplished by the use of bricks laid on their edges instead of their flat sides. In a single brick or 9-inch wall of the ordinary construction there are no hollow spaces, because, the bricks being laid with the width of the stretcher, being 4½ inches, it is equal to the length of the headers, that is, to say, 9 inches. If, however, the bricks be laid on edge, but otherwise disposed in the same way, while the headers are of course, of the same length, the width of the space between the edges of each brick at the face of the wall they will leave an intermediate space of 3 inches. Of course a lesser number of bricks will be required to produce an equal surface of wall by this than by the ordinary mode of laying.

Of the various departments of building relating to Carpenters and Joiners, brief notices will be given under those heads in P. C. S., with references to the various articles relating to them in P. C. Here it is only needful to observe that the portions of a building supplied by the carpenter should be so contrived as to strengthen and bind together the whole structure. The Roof, especially, of which a full account is given under that head in P. C., should contribute greatly to the solidity, as well as to the appearance of the principal portion of a house. In London houses, owing to the great value of space, slp., and rooms are very often formed in roofs; and in certain cases, when the ridge of the roof is made parallel to the front of the house in order to secure as much interior depth as possible, the front should be turned, that the back of the house is covered by a covered trough passing through the apartment formed in the roof, so that the fall of water from the roof may be equal towards the front and back, the pipe for conveying this water being made to pass safely under the roof, or to the fire. The provisions of the New Building Act respecting such rooms are alluded to in the next article. For the external covering of walls in which the brickwork is coated by a stoney-like composition, see Scarborough, p. 160; and for the lining of walls, the formation of ceilings, &c., see Plastering, P. C. S. Internal decorations are treated of under Painting, House, P. C., p. 145, and Paper Hangers, P. C., p. 215. More specific information respecting the various parts of a building will be found in such articles as Spacious, Door, Window, Arch, and Dome, in P. C., and Chimney, in P. C. S.; and under Fireproof Buildings, P. C. S., will be noticed some important deviations from the ordinary mode of building, in order to diminish the risk of fire.

BUILDING, ACT FOR REGULATING. Provisions for regulating the construction of buildings are generally introduced into acts for the improvement of towns. To permit buildings to be raised to a height and extent of streets, would be to sacrifice the public welfare to the caprice or convenience of individuals. There is no general measure ensuring uniformity of regulations for buildings throughout the country. In the session of 1843 the Marquis of Normanby, then a member of the government, moved for the better Drainage and Improvement of Buildings in large Towns and Villages, but it did not pass; and a bill of a similar nature was unsuccessful in the session of the following year. In the session of 1844, however, an act was passed (7 & 8 Vict. c. 84) entitled "An Act for Regulating the Construction and the Use of Buildings in the Metropolis and its Neighbourhood" and this measure, though applicable at present only to London, promises to be an important step towards the uniformity of regulations concerning certain modifications it will probably be extended to other places. The act came into operation on the 1st of January, 1845. London has had Building Acts ever since the reign of Queen Anne, but none of these were so complete as the present, and the provisions of it were calculated to check the spread of fire. The last Building Act, commonly called Sir Robert Taylor's Act (14 Geo. III. c. 78), was passed in 1774, "for the further and better regulation of buildings and party walls, and for the more efficient means of preventing and putting down fires, and for the placing of buildings of certain sizes within the Inns of Court and Westminster, and the liberties and other places within the bills of mortality, and to the parishes of St. Marylebone, Paddington, St. Pancras, and St. Luke's, Chelsea." The administration of the act was confided to district surveyors, each of whom had independent authority within his own district; but the magistrate at the nearest police-office might enforce or, not at his own discretion, the decisions of the surveyor. The technical regulations of this act were many of them, generally speaking, of so impracticable a nature that their evasion was connived at by the officers appointed to superintend the execution of the law; and it did but encourage the building of imperfect buildings in districts which have become a part of the metropolis since it was passed. Whether the new act (7 & 8 Vict. c. 84) contains regulations equally impracticable remains to be seen. Some of them probably are of this nature, as may be expected in attempts to legislate on technical matters of detail. However, the object of the act is excellent, and any defects in carrying it out may be corrected without much difficulty. The removal of sources of danger and disease in crowded neighbourhoods, and the enforcement of the provision for second tier in itself both wise and benevolent. The window tax will prove a great impediment to the act being fully carried out in several respects.

Some of the objects of the Metropolitan Buildings Act may be inferred from the preamble, which is as follows:—Whereas by the several acts mentioned in schedule (A.) to this act annexed provisions are made for regulating the construction of buildings in the metropolis, and the neighbourhood thereof, within certain limits, it is humbly suggested that plans have since been extended in nearly continuous lines or streets far beyond such limits, so that they do not now include all the places to which the provisions of such acts, according to the purposes thereof, ought to apply, and more such plans have been or are likely to be made; and whereas such plans and provisions for extending beyond such limits, and otherwise to amend such acts: and forasmuch as in many parts of the metropolis and the neighbourhood thereof, the drainage of the houses is so imperfect as to tend to make provision for facilitating and promoting the improvement of such drainage; and forasmuch as by reason of the narrowness of streets, lanes, and alleys, and the want of a thoroughfare in many places, the due ventilation of crowded neighbour- hoods is often impeded, and a host of the inhabitants thereby endangered, and from the close contiguity of the opposite houses the risk of accident by fire is extended, it is expedient to make provision with regard to the streets and other ways of access to the houses of the inhabitants, it is also expedient to regulate the height of buildings, forasmuch as by the carrying on in populous neighbourhoods of certain works, in which materials of an explosive or inflammable kind are used, the risk of accidents arising from such works is much increased, it is expedient to regulate not only the construction of the buildings, but such works as may also be permitted to be used either for habitation or for trade in populous neighbourhoods; and forasmuch as by the carrying on of certain works of a noisy, smoky, or offensive nature, or of such kind as are likely to produce wonder and abhorrence, the health and comfort of the inhabitants are extensively impaired and endangered, it is expedient to make provision for the adoption of all such expedients as either have existed, or shall be devised for carrying on such businesses, so as to render them as little noisome or deleterious as possible to the inhabitants of the neighbourhood; and if there be no such expedients, or if such expedients be not available in a sufficient degree, then for the carrying on of such works, as far as possible, they are prohibited, and forasmuch as great diversity of practice has obtained among the officers appointed in pursuance of the said acts to superintend the execution thereof, and for improvements in several districts which such acts apply, and the means at present provided for determining the numerous matters in question which constantly arise tend to promote such diversity, to increase the expense, and to retard the operations of persons engaged in building, it is expedient to provide for the appointment of officers to superintend the execution of this act throughout all the districts to which it is to apply, and also to determine in what manner and form such officers are to exercise in certain cases, and under certain checks and control, a discretion in the relaxation of the fixed rules, where the strict observance thereof is impracticable, or would defeat the object of this act, or would needlessly affect with injury to the course and operation of this branch of business: now for

* These acts are 4 Geo. III. c. 7, partly repealed; 80 Geo. III. c. 7, wholly repealed; and 3 & 4 Vict. c. 85, repealed so far as it relates to houses and buildings.
all the several purposes above mentioned, and for the purpose of consolidating the provisions of the law relating to the construction and the use of buildings in the metropolis and its neighbourhood, be it enacted, &c.

and take be proper the passengers With the consent of the owner, they may be

may be made without a good and sufficient drain leading to it. A drain under any building lining must be made air-tight. Privies built in the yard or area of any building must have a door and be otherwise properly enclosed, screened, and fenced from public view.

But if he by reference to his surveyor, or the official ref

and the by the referees the set of the

of building

the building, and by the referees at quarter-sessions for other parts of the metropolis. In all cases of dispute or difficulty the official referees appointed by the Secretary of State and the Commissioners of Woods and Forests will determine the matter, in cases, however, in which such referees have not been appointed by the occupier of the land, the minister of the parish of Kensington; and to all such parts and places lying on the south side or right bank of the said river, as are within the exterior boundaries of the parishes of Woolwich, Charlton, Greenwich, and New London, and within the environs of the City of London, the Liberties of Westminster, St. Barth, Streatham, Tooting, and Wandsworth; and to all places lying within two hundred yards from the exterior boundary of the district hereby defined, except the eastern part of the said boundary, which is bounded by the river Lee.

But it is hereby enacted that no petition in council to extend the above limits to any limits within twelve miles of Charing Cross, notice of such extension being published in the 'London Gazette' one month previously.

The exclusive of any building or other place in which buildings in a ruinous state may be situated, are required to apply to the official referees to authorize a survey to be made thereof. A copy of the surveyor's certificate is to be forwarded to the overseers (or to the lord mayor and aldermen, if within the city of London), and they are required to cause such ruinous building to be securely shored or a sufficient board to be put up for the safety of all passengers; and they are also to give notice to the owner to repair or pull down the whole or part of the building, if the owner does not within twenty days from the receipt of the surveyor's certificate, or the receipt of the official referees, and if the owner refuses to repair or pull down premises certified to be in a ruinous state, this may be done by the overseers, or in the city by order of the lord mayor and aldermen; and the materials may be disposed of to pay the cost of the work; and it is hereby enacted, if any failure occurs; and if any surplus remains, it is to be paid to the owner. But if the proceeds from this sale of materials are not sufficient to cover the expenses, the deficiency is to be made up by the owner of the property, and may be levied under warrant of distress; and if there are no goods or chattels to levy, the occupier of the premises may be required to pay, and he can deduct the amount from his rent. The same course which the act directs as to buildings in a ruinous state may be pursued as to every building, yard, or space, of whatever description, so far as relates to repairing or making them secure. If the projection be from the front walls of any building and be in danger of falling, the occupier, or if not the occupier, the owner, may be required to take down or secure the same within thirty-six hours; and a penalty of five pounds is incurred for every day during which the projection complained of is allowed to remain unrepaired or in a dangerous state.

The subject of party walls, party fences, and intermixed buildings is regulated by §§ 20 to 29, and the following provisions are made as to their reparation, pulling down, or raising. If the consent of the adjoining owner is not obtained, notice must be given to him three months before the work is commenced, and a written application to the official referees for such a modification of the work as will render it suitable to his premises. If the consent of the adjoining owner cannot be obtained, the matter is to be referred to the surveyor, and the official referees may order or confirm his certificate, and award the proportion of expenses, &c. The decision of the official referees is to be final and conclusive.

The 51st clause provides for a proper drainage. Before the walls of any building shall have been built to the height of a line of four feet, drains must hereby be made and made good leading into the common sewer, or if there be no sewer within one hundred feet, then to the nearest practicable outlet. If there be a common sewer within fifty feet of a new building, the drains must be made good leading into it. A drain under any building lining must be made air-tight. Privies built in the yard or area of any building must have a door and be otherwise properly enclosed, screened, and fenced from public view.
other parts of the building, every room used as a separate dwelling must be of at least the height of seven feet from the floor to the ceiling. 

§§ 54 and 55. How the restraint and eventual removal from populous neighbourhoods of trades which are dangerous, noxious, or offensive. Businesses dangerous as fire must not be nearer than fifty feet to other buildings; and new businesses of this character must be forty feet from public ways. Permits to erect buildings to exist or newly carry on such businesses within fifty feet of other buildings or forty feet from public ways; and all such businesses now carried on within the distances limited by the act must be given up twenty years after passing of the act. A penalty of five shillings is imposed for building in the neighbourhood of any such businesses, and 50l. per day for carrying on businesses of a dangerous kind contrary to the act. The persons offending may be imprisoned for six months if the penalty be not paid. The businesses of a multidriller, bont-boiler, fellmonger, slaughterer of cattle, sheep, or horses, soap-boiler, tallow-melter, tripes-boiler, and any other business offensive or noxious, are subject to similar regulations as those deemed dangerous as to fire, and are to be discontinued at the end of thirty years after the passing of the act. Traders deemed nuisances may be removed by purchase at the public cost on memorial by two-thirds of the inhabitants, and on the issue of an order in council. Public gas-works, distilleries, and other works and the survey of the Excises are excepted from the operation of the provisions contained in §§ 54 and 55.

The whole number of clauses in the act is 118; and there are a large number of other matters. The most important of these is the limiting of the length and width of buildings, for which the French, Lydia, in Asia Minor, has the distinction of being the earliest painter on record. He was a distinguished painter at least as early as 720 years before Christ. Pliny (H. N. xiv. 34) tells the following and more about the Lydia painted a building at Ephesus, which Canaceus, king of Lydia, about 716 B.C., gave him either the weight of the picture in gold or as much gold coin as would cover it. Neither of these versions may be true, but it appears evident that the picture was purchased by Canaceus at a high price. Pliny in another part of his work (vii. 30) speaks of this picture as representing the destruction of Magnesia; and the late K. O. Müller has, in his 'Archeologia,' on this account rejected the tradition, because the representation of Magnesia took place, according to Archolochus, about forty years after the death of Canaceus, through Ardyss, the successor of Gyges. Pliny however in the first instance mentioned, where he treats more particularly of art, calls it a Battle of the Magnetids, 'in qua erat omne sculpturae artis et acuta et oblonga.' This may be an isolated incident, but it is not an isolated fact regarding the early existence of painting in Asia Minor. There is much evidence in ancient writers to show that painting was one of the greatest achievements of the Ionian Greeks, while at the same period in Greece itself there is scarcely any evidence of its existence.

('Dictionary of Greek and Roman Antiquities,' edited by W. Smith, Ph. D., article 'Painting.') BULLANT, JEAN. When one considers the few early French architects of modern times, or of the Renaissance period, whose names have acquired historical celebrity, is supposed by Callet to have been born at Ecouen, at which place he died, in 1681. It is shown how diligently he studied the art; but the birth must have been about 1595. All that is known of his origin is that he was a retainer of the Montmorency family; that he visited Italy in his early youth, and returned from Rome in 1644. For an adequate opportunity of displaying his talents, as well as of acquiring and perfecting his art, he went to England, and had not to wait long, having been employed the following year by the celebrated Constable Anne de Montmorency, to erect, conjointly with Jean Goujon, the Château d'Écouen, in which work he took especial part. The monument of that lady remained unaltered, and has its present dignity and imbibed its spirit, by parading the 'orders' in a variety of ways. Yet notwithstanding the 'purity' and 'correctness' of taste claimed for its decorations of that kind, the whole is a grotto mixture of the ancien, or retrace the styles of the grottos of the moderns. We learn and note other respects distinctly French in physiognomy, with immense roofs, large and fantastically ornamented lunettes, and other characteristics of that age and country. Nay, even the gothic or French-Gothic style of the period was allowed to flow itself externally and very conspicuously also in the two windows, which are placed in one wing of the entrance-hall, while the entrance itself formed in the main façade, is decorated with Doric and Ionic columns, and a third order at the terminus in half-length figures. The principal altar of the chapel (now removed to that at Chantilly) was entirely in the ancient style of the time, and has been considered Bullant's masterpiece, —supposing him to have designed the sculpture also. At the time of the Revolution (1796), and subsequently, such very great changes were made, that the present condition of this château affords little idea of the original design. Of the palace itself, Bullant was the architect for Catherine de Médicis (originally called L'Hôtel de la Reine, and afterwards L'Hôtel Soissons), not even so much remains — in fact, nothing save the astrological column which stood in a niche on the façade of the house, which occupies the site of what was Catherine's residence. For the same princess he also altered and enlarged the Château de Chenonceau — the scene of fêtes and revelries more magnificent than decorous. Another work attributed to him is the Hôtel de Carnavalet at Paris, but this is somewhat doubtful. It is certainly certain that he was employed upon the palace of the Tuileries (begun 1564), although it is not exactly known what was his share in the work, and what the dates of the various parts. A statement, that he was not only of Catherine, but of Henri II. and Henri III. (under both of whom he held the office of comptroller of the royal buildings), he found another patron in Henri IV., in which capacity he carried out a portion of the palace at Fontainebleau, after the death of Louis XII. The end next the Tuileries. Bullant was the author of the works, viz. 'Règles Générales d'Architecture,' 1553; 'Traité de Géométrie et Horlogerie,' 1567; the front which is regarded as the earliest authority in the language on the subject of the so-called order of B. (Callet, Notice de quelques Architectes Français du Sei- sième Siecle.)

BUMASTES, a genus of Trilobites, thus named by M. H. B. M., in honour of the Messrs. Bullant or Barr Trilobite, which occurs in the upper Silurian strata.

BUNIUM, a genus of plants belonging to the natural order Umbelliferae, the suborder Orthocephalum, and the true Ammineae. It has an oblong calyx; obcordate petals with a broad obtuse indurated point; an oblong fruit, the carpels with 5 filiform equal ridges; the stigmas with 3 or 3 'vittae.' The species are perennial herbs with usually taberone and globose roots, square stems, compound leaves, and white flowers.

B. bullata, has the general involucr of 13 leaves, partial more numerous; fruit oval, narrowing upwards, crowned with the elongated stigmata and erect stigmas, internas with 3 'vittae.' This species is the B. bullata umbellata of De Candolle: it is the type of a single genus for which, however, the name B. bullata is satisfac-

tory in Great Britain. It has a nearly globular root, of a black or chestnut colour on the outside and white inside. It has an aromatic sweet taste, and is frequently dug up and eaten by children. It is called in Latin attached to the B. bullata as earth-nut, az-nut, kiper-nut, haw-nut, jar-nut, earth chestnut, and ground-out. The synonyms are as numerous in the French and German languages. Figs are very fond of this nut, and get fat when they are allowed to feed on them when boiled they are a pleasant and nutritious food. Roasted, they are preferred by some people to chestnuts, and are often in this country and on the Continent added to soup or broth.

B. Bulbocastanum of Linnaeus is a different species from the last. It is a small plant, with a soft root, and which deposits. Partial involucres are composed of numerous leaves, the fruit oblong, crowned with the short stigmata and reflexed style, the stigmas with single 'vittae.' This plant has lately been dis-
covered in chalky fields in Cambridgeshire and Herts, and is probably more common than is supposed. The B. bulbocastanum in the 'Gardener's Dictionary' sixteen species of Bumian. (Babington, Manual of Brit. Bot.)

BUNTER SANDSTONE, the lowest arenaceous series at the base of the coal-measures, as understood in Germany (the lowest part of our Coal-measure series). The three parts are —

Keuper above, marly.
Muschelkalk in middle, calcareous, and alternated with sand, as anarenaceous.
Oxford clay, calcareous, and arkose.

This classification is applicable to England by retrenching the middle term. Mr. Murchison is of opinion that part of the
Bouter Sandstein (Grès hâgré de France) belongs to the
Paleoecic series, but no proof of this is yet published.

BUONARROTI, MICHEL-AGNOLI. The Younger, was
born at Florence. He was the son of Leonardo di Buonarroti, brother of the great Michel-
Agno1, or Michel-Angelo, as the name is now usually
written; his mother was Cassandra di Donato Ridolfi. The Riti della Lettera Greca (1618),
the theatre of the great Hall of the Offices (Sala degli Ufizi)
in Florence. It was never printed till 1726, when 'La Fiera'
and 'La Tancia' were published in folio, with copious explanatory
and philosophical notes, by the same author. The latter,
mediagenichelagnolobuonarruotiigiovaneeLaTancia,Commedia Rustica
del Medesimo, coll' Annotationi dell' Abate Antonia Maria Salvini, Gentiluomo Florentino e Letteratore
Grecia nello Studio Fiorentino.' The notes of
Salvini to both pieces are very useful, though somewhat
pedantic.

Two other dramatic pieces by Michel-Agno1 the Younger,
'Il Natale d'Eroso' and 'Il Giudice di Paride,' have been
reprinted; they are of the class called masques. The 'Cico-
rate' is printed in 'Prose Florentine.' He also was the
first publisher of the poetry of his uncle, 'Rime di Michel-
Agno1 Buonarruoti, raccolte da Michel-Agnolo suo Nipote,'
Florence, 4to. 1623. Many other works in MS. may be said to be
in the possession of the descendants of his family.

(Life annexed to Salvini's edition of 'La Fiera' and 'La Tancia.')

BUONINSENGA. [Duccio di Buoninsegna, P. C. S.]
BUOYANCY is the power which certain materials have
of being supported at the surface of a fluid so as to sink in
it as much only as a part of their depth or thickness; thus ice,
some woods, &c. are said to have buoyancy in water. Almost
all solid bodies being immersed, the expression for the
buoyancy of a body being used for the weight by which a
solid mass of wood, or a vessel of wood or metal, can be made
to sink in water at its upper surface is on a level with that of
the water, or till a horizontal section of the body, at a
given depth, is filled with water; and the difference from the upper or lower surface of the latter, is on that
time.

It is shown [HYDROSTATICS, P. C.] that, when a body
is immersed in a fluid, the weight of the body with whatever
it may carry is equal to the weight of as much of the fluid as is
equal in volume to the immersed part of the body. Hence, if the
specific gravity of a body and that of a fluid be known (the former
being less than the latter), the buoyancy may be found. Thus,
by the rules of mensuration, find in cube feet the volume of
the body, and then divide the weight of the body by the
part only which is to be under water, and multiply it by the
specific gravity of water (the weight of a cubic foot of
the fluid), the product will be the weight of the water displaced :
subtract from this product, the weight of the body; and the
result will be the required buoyancy, or the weight which it
will carry without sinking lower than the given depth. If the
body, suppose it to be a log of timber, cannot be actually
weighed, the product of its volume by its specific gravity
will express its weight.

If it be required to find the volume of a rectangular mass of
timber, of given depth, which will support a given weight,
the following equation may be formed:

Let \( l \) be the length of a horizontal section through
the mass of timber, and consequently the horizontal surface
of the displaced water. Let \( d \) be the given depth of
the mass of wood and \( df \) the given depth to which it is to be
immersed. Let \( g \) be the specific gravity of the wood and \( g' \) that
of the water; also let \( W \) be the given weight which is to be
supported:

\[
\text{Then } s \times d \times g \times W = s \times d' \times g' \times W \]

whence \( s = \frac{d'g'}{dg} \)

this value of \( s \) being multiplied by \( d \), will give the required
volume.

In a similar manner may the buoyancy of casks or other
vessels be found, or the number of vessels which would be
required to lift any given weight; the volume of each is
found by the rules of mensuration, and the weight of a vessel by
experiment or by the volume and specific gravity of its solid
part.

This proposition is useful in determining the amount of
volume which would have buoyancy sufficient to raise a sunken
ship, or in determining the dimensions of a floating
bridge which may support a given weight of troops or artillery.

BUOYS AND LIFE-PRESERVERS. Many ingeni-
ous plans, more or less practicable, have been proposed
within the last few centuries for the preservation of life
in peril by shipwreck or otherwise. In Lords
Bray, P. C., several contrivances are noticed, which up to that
time had been suggested for this purpose, such as those of
Lukin, Greathead, Wilson, Brummet, Bray, Gordon, Ansell, &c.
Among these last, the so-called 'bronzard' may be grouped
under three headings, according as they relate to
boats, buoys, or garments.
Safety-Boats.—In 1859 Mr. Mackintosh of New York took out a patent for a sort of temporary life-boat. It consists of canvas rendered impervious to water by being saturated with a solution of caoutchouc. A square piece of this canvas is sewn to the lower edge of the boat, and then filled with air, when filled with air, may act as a buoyant cell or air-chamber. The opposite edges of the piece of canvas are partially sewn together, so as to give to it the semblance of a boat; the sewn edges being cemented with caoutchouc to make them water-tight. The stop-cock attached to it, furnishes the means of filling the sewn tubes with air from the mouth. The views of the inventor are, that if the air-tubes, forming a sort of gunwale to the boat, be of moderate size and not too close at any point, there will be support a person who might get into it on a sudden emergency. Water-tight coverings may be placed over the boat if necessary; and by making loops of thongs in the edge of the boat, oars might be used to propel it. The notion of the inventor seems to be, that a boat, capable of being folded up like a piece of cloth when not in use, may thus be made available in the water when necessary; and he also suggests certain modes of bringing the ship's mattresses to aid in the construction of a boat of larger size.

Mr. Adams, shortly after this time, contrived a form of safety-boat of more substantial construction. It has two bows, so that both ends are alike, thereby enabling the rowers to change their course without moving the head of the boat round. The boat is about seven feet long, and two steerers with oars is its instead of a rudder. The dimensions are recommended by the inventor to be about thirty feet long, nearly six wide, and rather more than two deep in the middle. The upper surface is lined with cork, and the total weight of the air-tight vessel, capable of containing from thirty to fifty gallons, made of tin-plate, copper, or India-rubber cloth, is fitted under the decks at each end; or else a large bulk of cork is used instead. When made of such dimensions, it is supposed that, with twenty persons in the boat, it would not sink even if filled with water.

In 1841 Mr. Salt of Shrewsbury described, in the 'Mechanics' Magazine,' a life-boat, the principle of which depends mainly on being able to make it water-tight. The boat is about six feet long by seven or eight wide; it has hanging-doors to let off the water; iron paddle-wheels to be worked by hand; and has ballast enough to sink it to the depth of about eighteen inches.

In the next following year a contrivance was introduced at New York, called the 'Man-over-Board Boat,' being intended to be thrown hastily into the sea to save any one who might have fallen overboard. It was, in a course of experiments, suspended from the yard-arm of a ship, at heights of thirty, forty, and sixty feet, and the end of the line was in the water; when let go, it descended into the water, but righted itself instantly; and the idea seems to be that such a boat might be made available with great quickness, in case of accident.

A life or safety-boat, also of recent origin, has some peculiarities about it, on account of its portability. It is formed of a skeleton frame, easily detached and folded into one-sixth of the space which it occupies as a boat. The frame is covered with layers or folds of strong canvas saturated with India-rubber; and in various parts are cases or air-cells, partitioned off one from another. The thickness of the canvas is increased according to the size of the boat, so as to give it a great degree of toughness, and at the same time an elasticity fitted to yield to any sudden shock without fracture. The portability of the boat is brought about by having the framework hinged to the keel, so that the sides close together like a portfolio; various minor arrangements being made to give fixation to it in the boat. The invention consists of a French one, but patented both in England and France. As an example of strength, lightness, and portability, a large boat in this form was tried in France in 1841. It was more than a hundred feet long; and, although formed of canvas sails, was carried with ease by a single man. The boat contained a shallow and almost interrupted stream. It was then taken to pieces in three or four minutes, and all the materials packed in a light bag, and sent by road to Auxerre. The invention of the life-boat by Mr. Taylor, of Leeds, was a kind of deck-chair, twenty-eight inches long by eighteen broad: it is capable of being quickly converted into a water-tight boat-shaped vessel, nearly as long, and capable of holding and supporting one person.

A number of other recent contrivances bear more or less on this matter; such as Captain Dansey's kite (1840) and Mr. Carter's rocket (1841) for carrying a rope to a wrecked or stranded ship; but most of these are similar to some or other of the contrivances proposed earlier.

Safety-Garments.—Corks and air-bags, attached in some way to the person, have often been regarded as a probable means of saving lives in case of shipwreck. These have given a new form to such contrivances. The upper part of the crown of the hat is made air-tight and water-proof, so that in the event of the wearer falling into the water, its buoyancy may (according to the intention of the inventor) save him from being drowned. The lining of the hat is capable of being loosened, and the vacant space expanded by air being blown into it, so as to form a buoy capable of being grasped by any one immersed in the water, instead of the hat itself. Mears, Macintosh have introduced a "life-clock" or cape, differing but little in appearance from those which are frequently worn in the streets; but capable, by the introduction of air through a stop-cock into a vacuum formed by a double thickness of the material of the cape; in case of being cast into the sea, by a description of this cape, it is stated that the inventor adopted three modes of testing its efficiency. First, that he calculated the volume of air which would support 15 lb. in the water—equal to the tenth part of the weight of an individual of about 10 stone; and therefore would keep the head and neck
Mr. Reece, in 1843, introduced a contrivance in which floating and respiration are both attended to. There is an inflated pad or cushion of India-rubber attached to the back to enable the wearer to float in water with his face uppermost; and the London Missionary Society have sent him a number of nostrils, sufficient to admit air for respiration, but to repel water. Another contrivance, that of Mr. Synington, consists of a peculiarly formed jacket or belt, capable of being quickly bound round the waist, and having buoyancy enough to keep the body afloat. BUPALUS, an early Greek sculptor of the island of Chios, and of a family long celebrated as statuiers, was the son of Anthermus mentioned by Pliny, and the brother of Athenis, and lived about the sixtieth Olympiad, or 340 a.c. He is better known for the eminence between him and the poet Hippoxanx than for his works, though both Pliny and Pausanias notice several of them. The quarrel between Bupalus and Hippoxanx is supposed to have originated in the sculptor refusing to give his daughter in marriage to the poet; who accordingly used his well-known satirical weapons against him; upon which the sculptor retaliated by executing a ridiculous statue of Hippoxanx, which, it seems, from some particularities of his work, led to his bad name. This plastic satire was revenged by the poet by some satirical iambics upon Bupalus, of so sanguine a nature, according to a report, no doubt false, as to make the sculptor hang himself. The story seems to have been common centuries after the time of Bupalus, for Horace, in the second satire on June the 23rd, makes one of his characters address himself to his friend Bupalus as a sufficient indication of Hippoxanx. Pliny (Hist. Nat., xxxvi. 5) speaks of works by the brothers Bupalus and Athenis, at Chios, Lesbos, Delos, and at Rome. Their father Anthermus was the son of Micles, who was the son of Malas. Upon some of their works at Delos they wrote, "Chios is not to be celebrated for its vines only, but also for the works of the sons of Anthermus." There is a sitting naked Venus in the Vatican, with Bupalus as the name; but it is evidently from its fully developed style, of a much later period than that of the subject of this notice. (Museo Pio Clementino, i. tab. 10.)

(Burleigh, Catalogus Artificum; Sillig, Catalogus Artificum; Thierry, Époques des Étendards-Kunst, 4to.)

BURLEUMER, from Stoe, oz. and παρθενος, side, a genus of plants belonging to the natural order Umbelliferae, the suborder Orithospermeae, the tribe Ammimenes. It has an oblong calyx; entire, roundish petals, with a closely involute, broad, clefted style; carpels with equal winged or filiform and sharp or oblong ridges; stigmas with or without vitre; stylopodium depressed. The species are quite smooth, herbs or shrubs. The leaves are roundish, in most instances being quite entire, in others from their pinnate or palmate or palmatifid form: they are composed entirely of the petioles, and are in fact phyllidia. The flowers are yellow.

There are about fifty species of Burleumera. They are natives of temperate climates in most parts of the world. They are known by the common name of Hare's-tail. When eaten by cattle they are supposed to injure them and cause dis- tension of the abdomen; hence the generic name. B. rosmarinifolium is a beautiful species of Burleumera. It has a branched stem with flat perfoliate leaves, and the fruit with astrate insectivores. It was supposed to possess especial virtues as a vulnerary, but there is no notice now that wounds are better without any such applications. There are three other British species, B. tenaxfruticum, B. aristatum, and B. folax. The species are sometimes cultivated in gardens. The annual species only require to be sown in the open ground early in the spring. The perennial may be increased by dividing their roots; the shrub by cuttings.

D. D. (Museum D. D., Mem. of Brit. Bot.)

BUPRESTIS (Fossil). The elytra of beetles found at Stonesfield have been referred to this genus.

BURBURY. [Bradbury, F. C. S.)

Bradbury was born in London on the 25th of May, or, according to the New Style shortly afterwards, introduced the 6th of June, 1752. As he showed an early taste for drawing, he was placed under the tuition of an artist named Isaac Taylor. About 1776 he became a student to the Royal Academy; and shortly afterwards he began to

preach, and at length determined to relinquish his profession, and to devote himself wholly to the Christian ministry. In 1778 he became pastor of a Congregational or Independent church at Lancaster; in 1783 he removed to Coventry, during his residence in which city he took an active part in the formation of the London Missionary Society; and in 1787 he waited a conspicuous call to the pastorial of the Congregational church at Fetter Lane, London, his removal to the metropolis being further urged by a request to undertake the offices of secretary to the London Missionary Society, and editor of the London Missionary Magazine, then vacant by the death of the Rev. John Eyre. The duties of these offices were performed by Burbury with much zeal and peculiar talent, until increasing years and infirmities compelled him to resign them; and, during a period of more than twenty years, after his removal from Coventry, he took a prominent part in the various religious movements of the body with which he was connected, and of which he was one of the most influential and universally respected members. Burbury died at the age of eighty, on the 29th of May, 1832. His publications, which were numerous and exceedingly useful, consisted chiefly of religious essays and sermons of a peculiarly simple character, which have gained a high reputation far beyond the limits of his own religious denomination. Of these the best are his three volumes published at various times between 1779 and 1819, and which have been repeatedly reprinted, and translated into several European languages, are perhaps the best known. Of forty-eight "Sermons," "Four Great Sermons," "Evangelical and Reformed" (from Detmold), "Words of Life," "Pastoral and Practical Homilies," "Old Age," written for the Religious Tract Society, the aggregate circulation during his life amounted to little short of a million copies. Among his other publications were, 'Evangelical Truth Defended,' 8vo., 1788: an abridgment of Dr. Green's "Preliminary Discourses," edited by Symington; "The Pilgrim's Progress," 8vo., 1791; "The Christian Portal," 8vo., 1792; and "The Pilgrim's Progress," 8vo., 1793; or, A Collection of Papers respecting a people whose ancestors emigrated from Wales to America in 1717, with Prince Madoc, and who are said now to inhabit a beautiful country on the west side of the Mississipi River, which ibo, My autobiography Sermons, 12mo., 1810; and a new edition, revised and considerably extended, of the Rev. Laurence Howell's 'History of the Bible,' in three volumes, 8vo. and 12mo., 1807. Burbury also edited Bunyan's 'Pilgrim's Progress' and 'Holy War,' and Matthew Henry's 'Commentary,' and published several other works, some of which are mentioned in an obituary notice in the 'Gentleman's Magazine' for July, 1793, and in the 'Memorials' published in 1853 by his eldest son, Henry Forster Burdett, D. D., water Burdett, D. D., and Geographical. There is also a pretty full account of Burdett in Dr. Morison's 'Fathers and Founders of the London Missionary Society.'

BURDETT, Sir Francis, Bart., was born on the 1st of January, 1770, and was the third son of Francis Burdette, second son of Sir Robert Burdett, Bart., of Bramcote, Warwickshire. His mother was Eleanor, daughter and co-heiress of William Jones, Esq., of Ramsbury, in Wilts. Before the death of her husband, Sir Robert Burdett, he had attempted to fit himself for the bar; but, on his grandfather's death, his father became the title; the subject of the present notice had lost both his father and his two elder brothers; and, his father's elder brother having previously died, he became baronet. His father had died in 1784; and Sidney, the last of his two elder brothers, had been drowned, along with Lord Montague, in 1793, in attempting to cross the falls of the Rhine at Schaffhausen in a small boat. The baronetess had been conferred in 1618 upon his great-great-grandfather, Sir Francis, said to be the son of the ancient lineal descendant, Hugh de Burdett, who came over with the Conqueror. Thomas Burdett, who was put to death in the reign of Edward IV., for wishing that the man who had moved the king to kill a favourite white buck in his park at Yarow had the horns in his belly, was an ancestor of the baronet. Sir Francis was educated at Westminster School, and afterwards spent some years on the Continent. In 1798 he married Sophia, youngest daughter of the late Thomas Coutts, Esq., banker. In 1796, being still Mr. Burdett, was, by the consent of the Directors of the Bank of England, sent to Yorkshire, his colleague being Sir John Scott, afterwards Earl of Eldon and Lord Chancellor. A few years subsequent to this, on succeeding to the estates of his mother's brother in addition to his own, Sir Francis assumed the name of Jones, which however he soon afterwards resigned. From his first entry into parliament Sir Francis had followed an extreme course of popular politics, opposing the government and the war, advocating a reform in the representation, and especially distinguishing himself by an inquiry
which he got set on foot into the abuses of the Cold Bath Fields and other prisons. This led to his being brought forward in the election for Westminster in 1802 as a candidate in the representation of Middlesex, in opposition to Mr. Mainwaring, who was chairman of the County Sessions, and had been the person by whom the investigation into the prison abuses was chiefly resisted, and impeded in Westminster. The public excitement which this contest occasioned was unprecedented. It ended on the 15th day by giving Sir Francis a majority of 371 votes over his opponent; but a committee afterwards declared the election void, and the proceedings altogether at a cost Sir Francis had paid above a hundred thousand pounds. At the next general election, in 1806, he was again proposed for the county; but this time he only polled 1197 votes, and Mr. Mellish was returned. In May, 1807, a duel took place between Sir Francis and Mr. James Paul, a lawyer, who supported Mr. D'Ewes as his candidate. Westminster the year before: they fought at Combe Wood near Wimbledon Common, and at the second exchange of shots both were severely wounded. While they lay ill, both were put under the recommendation of Liborius, the name of the new general election; and the result was that, after a contest of fifteen days, Sir Francis was brought in at the head of the poll, having obtained 5134 votes (his colleague Lord Cochrane only polling 3708), and that Faul had left fifth, and at the bottom, with only 295. At the preceding election Faul had obtained 4365 votes, being only 277 under Mr. Sheridan, the successful candidate. Sir Francis continued to sit for Westminster from this time for nearly thirty years. The great event of his subsequent career is his connection with the Tower, by the House of Commons, in March, 1810, for a letter to his constituents denying the power of the House to imprison delinquents, which was published in Cobbett's 'Political Register,' and which the House voted to be libellous and scandalous. He attempted to resist the Speaker's warrant, and some lives were lost in a street contest between the military and the people; but he was eventually surrendered, of course, and was layed in prison from the 9th of April till the prerogation of pardons. Sir Francis was continued to sit for Westminster to the popular side in politics till some time after the appointment of the Melbourne ministry, in April, 1835, when he went into opposition against his old friends in the government, on the ground principally of the court being charged them with perjury, and his friends in the court against the Irish established church. In these circumstances he declined standing for Westminster at the general election in July, 1837; but he was returned for Wiltshire, and he sat for that county till his death, which took place on the 2d of January, 1844. Lady Burdett had died only a few days before.

(Burgharlary, vol. v.; Beaton's Chronological Register of Parliaments; Annual Register; Parliaments and History; Biographical Index to House of Commons; &c., &c.)

BURDIE HOUSE, a locality near Edinburgh, where a thin band of carboniferous limestone, remarkably rich in En
tomographical insects, spiders, and other land plants, occurs. It has been described by Dury, in the Catalogue of the Royal Soc. of Edinburgh.

BURGAGE HOLDING, one of the forms of feudal tenure in Scotland. The holders of the fiefs under the charters of the feudal barons and the landholders under the curia

crown, returning service by watching and warding. The return is now merely nominal, but the holding is still of the crown, though the investiture is given by the magistrates of the burgh. The personal service of the baron character is now

preserved in modern practice the important distinction, while other descriptions of landed property may be sublet at minimum, a burgage holding can only be transferred from one crown vassal to another, who comes in his place. All transfers, to constitute real rights, must be followed by saisine recorded in the books of the sheriff clerk of the burgh. All rents are paid to the baillie, who is appointed by the burgh by burgage tenure. The community may, like an individual, obtain feu rights and grant subinfeudations; the proper bur

gage holding is applicable only to those lands to which

other granting burgal privileges for the usual return, applies.

BURGMAIR, HANS, a celebrated old German painter and wood-engraver, born at Augsburg in 1472. He lived some time in Nuremberg, and was the contemporary, and by some accounts the pupil, of Burkhard Hartmann. A new view of the monastery was first published in 1505. Dürer was directly or indirectly the source of everything excellent in art that was produced in his own time and country.

There are still several excellent paintings in oil, for their period, by Burgmair, preserved in the galleries of Vienna, Munich, and Schleissheim; and there are others at Nuremberg and at Berlin. He painted also in fresco and in distemper, and he illuminated manuscripts; but he is better known for his woodcuts, or at least those cut from his designs, which amount to thousands altogether, and are the best wood-engraving of the Emperor Maximilian I., in 156 large cuts, with a description by the emperor, is one of his chief works; it was executed in 1519, the year of Maximilian's death, chiefly by Burgmair; some of the prints are marked with his name, and others with the name of his son-in-law, with assistance, another series of cuts in commemoration of the same emperor, entitled Der Weisse Kunig (The Wise King), of which there are 237 large cuts, being illustrations of the deeds of Maximilian, from the description of H. Sauerwein. The emperor is said to have superintended the work himself. The blocks are still preserved in the library of Vienna. There is also by Burgmair an equestrian portr

tait of Maximilian, in chiaroscuro, dated 1518. He cut also an excellent portrait of Johann Baumgarten, dated 1512, and a picture of St. George on horseback, both in chiaroscuro.

On Burgkain's prints in chiaroscuro another name occurs beside his own—Jost de Neger, to whom probably the execution of the chiaroscuro is due. Besides these and many other woodcuts, there are several etchings and two engravings attributed to Burgmair. His paintings are carefully and solidly executed, but are Gothic in taste; there are ten in the Pinkasothek at Munich, of which that of the three sain

Liborius, Eustace, and Roch, is strikingly excellent in its style (Cabinet ii. No. 24). In the gallery of the Belvedere at Vienna there is a picture by Burgmair of himself and his wife, with their ages inscribed upon it, dated May 10, 1528. The painting is five feet high and ten broad, but it is supposed to have been 1559. Sandrart has given a portrait of Burgmair in his 'Teutsche Academie,' &c., and there is a print by G. K. Killian, of the Vienna portrait of Burgmair and his wife.

BURLANDI, ANTONIO, a 3-celled, 3-branched sterile

BURLANDI, ANTONIO, a natural order of plants belonging to Lindley's group of epigynous Endogenae. It was first con

stituted by Sprengel as a separate order, and in somen-

times made a section of Asaridaceae. The species of plants be-

longing to this order are herbs, with alternately toothed leaves, or none at all, with terminal flowers, which are sessile upon a 2- or 3-branched rachis, or solitary. The flowers are hermaphrodite; the perianth tubular, superior, coloured, mec

branous at the base, the stamens as many, the ovary large with a wing or keel at the back; the stigma 3, in

serted in the tube opposite the petals, with sessile 2-celled anthers opening transversely with a flabby connective, and sometimes 3 sterile stamens alternate with them; the ovary superior, and the fruit globose, though often longent with the wings of the perianth; the style single; the stigma 3-lobed, petaloid; the capsules covered by the withered perianth or 5-celled, bursting irregularly; the seeds being numerous, minute, striated with an aril, fleshy albums, and minutely arillate.

The genus Burmannia, on which this order has been founded, is variously assigned by different botanists. Jussie

placed it in Brunallaeae, Brown in Junceae, Von Marta
in Hydrocharaceae, Blume places it between Juncaceae and Irídeacéae, Lindley near Hémadalzaceae, and there can be little doubt of the propriety of constituting it a distinct order. The species are natives of Asia, Africa, and America. The genus refers to this order are Burman, Triptérella, Gomphtheros, Gynacodíseum, Apocynum. The have not very conspicuous properties; the Apteris sectae is said by Nutall to possess tonic and attritious properties. Triptérella cerasul is also said to have a flavour very similar to that of wine.

(Lindley, *Natural System*; Burnett, *Outlines of Botany*.)

**Burnes, Sir Alexander**, born May 16, 1805, at Montrose, in Scotland. His father was an active magistrate of Forfarshire, and he early successively the chief official situation. The oldest son of Montrose, the brother of William Burnes, father of the poet Burns, who was the first to omit the letter e from the family. Alexander Burnes was educated at the Montrose Academy, in which he greatly distinguished himself. Having obtained a cadetship in the Bombay army, he left school at the age of sixteen, and arrived at Bombay Oct. 31, 1821. On the 25th of December, 1822, he was appointed interpreter in Hindustanee to the 1st extra battalion at Surat, and, on the account of his proficiency in the Persian language, the Judges of the Sudder Adlánaut appointed him, without solicitation, to the office of translator of the Persian documents of that court.

In consequence of disturbances in Cutch, the regiment was sent on a voluntary expedition not only to Bokhara, but also to Persia, where he was second in command, and, having been ordered to Bhojó, he joined it there in April, 1825. He was soon afterwards made quarter-master of brigade, and in November, 1825, when he was only twenty, was appointed Persian interpreter to force of eight thousand men, and accompany the invasion of Scinde. In April, 1826, he was confirmed on the general staff as deputy-assistant-quarter-master-general.

At this period he drew up an elaborate paper on the statistics of Wagir, for which, in 1827, Licut, Burnes received the thanks of the Bombay government and the special commendation of the Hon. Mountstuart Elphinstone, the governor; and he obtained similar testimonies of approbation in 1828 for a memoir on the eastern boundary of the Indus. Burnes was present in the battle of Baluchistan, on March 18, 1826, and in Sept., 1829, was appointed assistant to the political agent in Cutch, in procession of the survey of the north-west frontier. (He has given an account of this survey in the Transactions of the Royal Geographical Society for 1834.) He soon afterwards made a journey into Rajpo- tana, from which however he was recalled; and in 1830 was appointed by the Indian government to proceed to Lahore, where he had managed Bannerman, the son of the king of England to Russia, and was the head of the Punjab. The details of this expedition are given in the third volume of his Travels into Bokhara. The mission was directed to proceed by the devier route of Scinde; the secret object being to obtain first-hand knowledge of the Kootali, and Cutch, and to make the acquaintance of the Indian and Central Asian deputies, with letters to the Ameers, and, the better to obviate suspicion, he took with him a guard of wild Beloochees. The mission sailed from Mandavi in Cutch, Jan. 21, 1831, and on the 28th reached the western mouth of the Indus. After a long and tedious negotiation with the rulers of Scinde, Burnes received their full sanction to proceed by water from the mouth of the Indus. The delay however had been too account. Burnes bad made a complete survey of the mouths of the river, and a map of the country for himself of course. After spending a week at Tatta, they set sail up the river, April 12th, and reached Hyderabad on the 18th, where he was received with great cordiality by the Ameers. The mission remained at Hyderabad till the 22nd of April, when they re-embarked on the Indus, and after visiting all the places of importance along the banks, on the 18th of July they arrived at Lahore, where their reception was magnificent, a deputation of nobles conducting the envoy and his suite to the door of the palace of Runjeet, when, as Burnes himself says, 900 camels and 100 bullocks, or ‘stoooping,’ says Burnes, ‘to remove my shoes at the threshold, I suddenly found myself in the arms and tight embrace of a diminutive old-looking man, the great maharaja Runjeet Singh, who conducted me the hand to the interior of the court, and introduced me to all that was proper to do as a guest.’

After remaining till the middle of August with Runjeet Singh, who treated Burnes with the familiarity of a friend, the mission left Lahore, crossed the Sutlej, and proceeded to Loodiana, a frontier station of the Indian government, where Burnes became acquainted with the ex-mogul of Cabool, Shah Zeman and Shah Sabjojah, who were living there under the protection of the British government. From Loodiana the mission proceeded to Simla, where Burnes met the governor-general, Lord William Bentinck, who without delay entered into negotiations for laying open the navigation of the Indus to the commerce of the world.

After his return from his mission, Lieutenant Burnes proposed to Lord William Bentinck an expedition into Central Asia, which received from his lordship the most liberal encouragement.

The sanction of the Indian government having been obtained, the journey was commenced in January, 1833. Lieutenant Burnes was well provided with instruments, and made his journey a kind of flying survey. Arrowsmith’s map, compiled from his labours and every other available source, is probably the most perfect now existing of the countries which it embraces.

Burnes left Delhi, accompanied by Mr. James Gerard, surgeon of the Bengal army, Dec. 23, 1831, and proceeded by express to Loodiana. Previous to entering on his journey, it was deemed necessary to obtain the sanction of Runjeet Singh to pass through Scinde. He descended the Sutlej, and reached Lahore Jan. 17, 1832, and was received by the maharaja with all his former affability. Their departure was delayed till the 11th of February, when, after crossing a number of the greatest mountains, they arrived at Bumbay for the night. The close doors, beds, boxes, tables, and chairs, were all dis- carded for a flowing robe, a coarse carpet, and a blanket; and their now diminished wardrobe, with the necessary books and instruments, were deposited in their saddle-bags, and thrown across horses’ necks, as a precaution against their horses’ being dispersed and lost.

The troops of Runjeet Singh escorted them across the Chenab and the Jelum to their frontier, about three miles beyond Attock, where they met the Afganis, and proceeded with them to Acora, where they remained several days. They crossed the Oxus, and entered Persia, where they joined the Russian army, by which they left April 19, under the protection of one of Mohammed Khan’s officers; and passing through Jallalabad, reached Cabool by the Latabund Pass, April 31. They departed from Cabool May 15, and leaving Ghuznee on the south, advanced northward direct to Kabul, which they reached on the 25th. They then crossed the mountainous border of the Huazar, and ascended the pass of Hageceguk, 12,400 feet high, May 22. The snow bore their horses, and the thermometer fell to 4° Fahrenheit at the base of the mountain, or 57° above sea-level; and they ascended the pass of Kaloo, 1000 higher than that of Hageceguk, but were hindered by the snow, and passed round its shoulder, but were unable to continue their route on horseback, and on foot.

After stopping a day to examine the wonderful excavations and remains of the ancient city of Ghoolgoola, they crossed the pass of Acrobat, which separates the dominions of modern Cabool from Turkestan, or Tartary. After crossing the Dunand Shikan, or Toothbreaker, and the Cabool river, on the 28th, the Russian army, under their last march among the mountains of the Indian Caucasus, and descended into the plains of Tartary at Khoooloom, the frontier town of Mordé Beg, the chief of Khoooloom, and there delayed by the strange appearance of the presence, at the village of Kaumabaud, about fifty miles distant. Burnes as- sumed the character of a poor Armenian watchmaker journeying from Lucknow to Bokhara, and in his torn and threadbare garments happily escaped detection, received a pass of safe conduct, and was conducted to the town by a Russian officer (who accompanied him), and on the 7th of June rejoined his friend Mr. Gerard, who had been left at Khoooloom.

On the 6th of June they again set forward, and reached Bokhara on the 15th, where they spent some time in exploring the ruins of that ancient and once magnificent city, on the 12th they set forward at midnight on camels bearing panniers which held one person on each side. On the 14th they entered the desert, and on the 16th reached the bank of the Kara, or Bokhara river, 110 miles wide, 2000 feet wide, crossed in boat, each drawn by two horses, which swam across the stream.

On the 27th of June the party reached the great eastern capital of Bokhara, where they remained six days. They then waited in the neighbourhood of Karakool till the 16th of August, when they accompanied a caravan, consisting of about 80 camels and 150 persons, some in panniers on camels, some on horses, and some on ass. In this manner they passed the great desert by Merv, and reached Meshid on the 14th of September. On the 17th they reached Koo-
B U R N E T T, GILBERT THOMAS, was born in Marseilles, on the 15th of April, 1800. He was educated for the medical profession, and paid the usual visit to India. He commenced lecturing on botany at the Hunterian theatre in Windmill-street, and afterwards lectured at the St. George's School of Medicine. On the foundation of King's College, he was appointed the first professor of the science. In 1833 he became lecturer to the Society of Apothecaries, and delivered two courses at their gardens at Chelsea. In the same year he published his 'Outlines of Botany,' in 2 vols. 8vo. This work extended an outline of the author's lectures on botany in King's College, 1833, and contained a complete and practical catalogue of facts relating to the history and uses of plants. There is another feature also which has rendered it of great assistance to the student of botany: it contains a very extended introduction to the study of crypto-phyllous plants. The author, however, was too fond of mere verbal classification, and has overlaid the whole work with divisions and sub-divisions that make confusion rather than facilitate the student to discover the valuable matter which the work otherwise contains.

Mr. Burnett was latterly engaged with the bringing out this great work to devote himself to original research. That he was capable of this is however proved by his papers published from time to time in the 'Journal of Science and Art.' These papers are on various departments of natural history, comparative anatomy, and zoology, as well as botany. The most important are those devoted to physiological botany. In one of these he endeavoured to prove that what had been called the respiration of plants, viz., the taking in of carbonic acid and the giving out of oxygen, was truly the digestive process of vegetables. He also endeavoured to prove that there was a true respiratory process carried on in plants; that they not only took in carbonic acid and gave up oxygen, but that they also took up oxygen and gave up carbonic acid. This theory has been adopted by many continental chemists and botanists, but it appears that the most rational explanation of the phenomena of plants giving oxygen in the day, and taking carbonic acid in the night, is not that it is really a respiratory process, but from the giving out of carbonic acid, which, being taken in by the roots, is not decomposed for the want of the light of the sun. He also contributed several papers on medical subjects to the 'Lancet' and Medical Gazette,' and was an active member of the Westminster Medical and the Medicinal-Botanical Societies.

As a lecturer, Professor Burnett was remarkable for his fluent and graceful style, and his amiable manner was very acceptable to his pupils. He removed to his new apartment in the summer of 1835, of pulmonary consumption. He continued his lectures till within a few days of his death. A besotted by Bohnes, and subscribed for by his pupils, has been erected to his memory at King's College.

B U T E A , a genus of plants belonging to the natural order Leguminosae, named after John, Earl of Bute, a great lover of botanists. It has a campanulate calyx, 5-toothed, the two outer petals longest and longest. It has 1 seed in the pod, which is attached in the manner of the capsule to the peduncle, the valves opening. The true flowers are umbellately disposed, the flowers being solitary and the fruit a pod-like capsule, containing 10 to 20 seeds, each of which is provided with a wing or beak, and which develops from the fleshy ovary of the true flower after it has been fertilized by the pollen from the stamens. The fruit is ovoid, the pericarp thin, and the seeds large, yellow, and oblong. The leaves are alternate, simple, and entire. The flowers are small, white, and fragrant. The whole plant is covered with down, and the stem is branched. The leaves are entire, and the flowers are in clusters. The fruit is a pod-like capsule, containing 2 to 10 seeds, each of which is provided with a wing or beak, and which develops from the fleshy ovary of the true flower after it has been fertilized by the pollen from the stamens. The fruit is ovoid, the pericarp thin, and the seeds large, yellow, and oblong. The leaves are alternate, simple, and entire. The flowers are small, white, and fragrant. The whole plant is covered with down, and the stem is branched.

time refused to be again put in nomination for that or any other borough. In 1840 the crown conferred on him the dignity of a baronet. Though afflicted with ill-health, he did not cease his benevolent exertions and was one of the chief promoters of the well-meant but disastrous expedition to the Niger in 1841. He died on the 19th of February, 1845, at his residence North-Repe Hall, near Alysham, in Norfolk, at the age of fifty-nine.

Sir Henry Buxton was a man of singularly commanding person; he was more than six feet four inches in height, and of a fine expression of countenance. As a speaker, he was somewhat heavy both in style and delivery, but in the exercise of his profession from his altered character always commanded a respectful attention. He had no great reach of intellect or imagination, and little of the fervour of an orator, but in collecting facts his industry was untiring, and in exhibiting and commenting upon them, he was zealous to peruse and make one of his recent inventions was the pendulum which revolutionised the practice of horology, by regulating the rate of the clock. He had not only the knowledge of the properties of the numbers called logarithms, but furthermore, with the aid of logarithmic computations, he was able to form a table of those for every degree of the circumference. It is remarkable that Kepler, who himself computed a table of logarithmic numbers, does not mention Byrgius's discovery as the most useful that had been made since numbers were known. If then, the by epochs, and of his intelligence, Napier was not the first to have been used in mathematics and astronomical instruments. He is said to have invented a instrument similar to that which is now called logarithmic compases; and to have constructed a pendulum clock in the year 1675, which was above fifty years before the application of a pendulum to an instrument for measuring time was made by Huyghens. He executed for the landgrave a celestial globe and orrery, which was afterwards purchased by the emperor Rudolph II, who appointed him his instrument-maker.

His brother-in-law Brunier states that on the death of the landgrave he went to reside at Prague; and that in 1692 he returned to Casell, where he died in the following year. Dithmarus, who designates himself a pupil of Byrgius, observes that the latter had studied neither Latin nor Greek; and Kepler describes him as an indolent and reserved man, who withheld his discoveries from the public.

Dithmarus ascribes his tutor the discovery of two rules for resolving spherical triangles; one, when the three sides, and the other, when two sides and the angle contained between them are given; and he considers them as much more simple than any which had been used before that time. He states also that Byrgius had discovered a method of dividing any given angle into equal parts, or in other words having given the relations to one another; and he adds that by such means he could compute with great facility a table of sines, either in natural or in logarithmic numbers. These last are supposed to be a species of logarithms, and as the work of Dithmarus was published in 1588, or twenty-six years before the Canon of Napier (Napier, P. C.), it is possible that Byrgius may have preceded the latter in the time of the discovery. This is directly asserted by Kepler, who refers to the Rudolphine Tables, in which it is observed that the Logistic Indices (the accents by which minutes, seconds, thirds, &c. of a degree are designated in sexagesimal arithmetic) led Byrgius to the discovery of logarithms similar to those of Napier. If the latter had not been acquainted with Dithmarus's work, it may, in fact, have been formed by the means obscurely indicated in the work of Dithmarus, two series of numbers, one series in an increasing arithmetical progression, and the other in a decreasing geometrical progression; like those denominations above alluded to, and as in the original table of logarithms computed by Napier.

From Montucla ('Histoire des Mathématiques,' tom. 2) we learn that there is a passage in a work on Perspective by the Belgian artist, Van Campen, which is said to have been published in 1630, a table containing two series, one in arithmetical and the other in geometrical progression; it is added, that he entertained the idea of publishing such a table, and committed it to paper every two seconds of the quadrant, and that the distance occasioned by the Thirty Years' War prevented the design from being put in execution. An imperfect copy of the tables first mentioned was in the possession of M. Kistner, and from this it was found that the logarithmic numbers begin with zero, and increased constantly by 10, while the natural numbers begin with 1, and form an increasing geometrical progression. Brunier infers from the publication of this table, that his brother-in-law was in possession of logarithms long before Napier had made the discovery; but, as the 'Catus Mirificus' was published six years earlier than that table, his inference is not sustained. It must be remembered that the circumstances mentioned by Dithmarus, that twenty-six years before the publication of Napier's book, Byrgius had knowledge of the properties of the numbers called logarithmic, are in strict accordance with the circumstances mentioned by Dithmarus, that twenty-six years before the publication of Napier's book, Byrgius had knowledge of the properties of the numbers called logarithms similar to those of Napier. Previously to the time he always spoke of Napier as the inventor, and of his discovery as the most useful that had been made since numbers were known. If therefore it is said that Napier had knowledge of the discoveries of Byrgius from the work of Dithmarus, it cannot be supposed that the latter had found its way to Scotland, or that its obscure indications guided Napier to his discovery which has immortalized his name.

Byrgius is designated as the discoverer of a species of logarithms, known as the logarithmica, by E. J. G. Linnuces, belonging to the family of Brythridae as defined by Leach. The beetles composing it are more or less globose, very convex, and sericeous; the club of their antenna is frequently composed of a series of long pointed segments, arising concentrically, and enveloping the larva, which is covered with a layer of thin silvery or whitish dotal, and the porion, which is composed of the terminal segments smaller than the others. Seven British species of Brythridus are enumerated by Mr. A. H. Haliday in his 'Systematic Catalogue of British Beetles.'

An account of the family see Westwood's 'Introduction to Entomology.'

BYSSA/CÉ/ÉE, a tribe of Cryptogamic plants, raised by some botanists to the importance of a distinct order, others refer it either to the Lichenes or to the Fungi, and distribute its genera amongst the various orders of Cryptogamia.

Fries places this group of plants in the natural order of Lichens, with the following definition:—Aerial, perennial, constantly growing, with a filamentous texture; consisting of solid fibres (either few, or several glued together, with a common bark), unchanged and permanent. Fruitication homogeneous, growing externally and naked. Many of the species of plants referred to are of great importance in the chemistry of vegetable and animal matter have undoubtedly been described as plants, and placed amongst them. These forms of matter, whatever they may be, are not less interesting to the naturalist than if they came under his notice as the fortunate offspring of a plant.

The genus Rhizomorpha (Rhizomorpha, P. C.) is referred by most botanists to Byssaceae. Some authors have decided their specific vegetable character. The various forms are found on decaying wood and on vegetable matter, in the coal-mines of Dresden they form objects of great interest on account of their phosphorescence. Mr. Erndt, quoted by Burnett in his 'Outlines of Botany,' gives the following account of this phenomenon, in one of the Dresden mines, 'when the sun is shapely, the plants are seen to be most beautiful: the impression produced by the spectacle shall never be forgotten. It appeared, on descending into the mine, as if we were entering an enchanted castle. The atmosphere was pure, the plants were green, the walls and the pillars were entirely covered with them, and the beautiful light they cast around almost dazzled the eye. The light they give out is like faint moonshine, so that two persons near each other could readily distinguish their bodies.' Another species, 'Rhizomorpha cinchonarum,' is an evident of the subpercutent state of the barks on which it is found. 'Racodium' is a genus referred by Fries to this group of plants. The R. collare is a common plant in winter.

Cellars, where it forms a kind of tapestry on the walls and roof, investing the casks and bottles with a tunic resembling in colour and appearance the skin of a mouse. Hypocnus is a genus found on the decaying bark of trees. When found on bare black mould, the species should be rejected as unfit for use, as this plant indicates incipient decay.

The genera Monilia and Aspergillus are sometimes referred to fungi. The species of these genera, with many others, form what is known by the name of mould on various substances. [Mouldiness, P. C.]

Monilia penicillata is commonly found on plants in herbaria. The various forms of Aspergillus are found on all kinds of decaying substances. A. penicillus is the blue mould which forms on fragrant substances, it should be rejected as unfit for use, as this plant indicates incipient decay.

Most of the species of the old genus Byssus are distributed amongst other genera. B. Iolathus, the violet-scented byssus, is found of a deep red colour on boarded buildings, old pales, and trunks of trees, on rocks in mountainous countries, and on walls. It is now called Lepraria. It is not less remarkable for its violet scent than its red colour. [Seyou, Rax, P. C.]

There is another plant, Ceroplesis Iolathus, which was included under the Byssus Iolathus of older writers.

Byssus cryptorus forms the genus Tophora of recent writers. Several species of Tophora have been named. They do not however produce spores, and by some they are supposed to arise from the germination of these so-called forms and moses arrested in the rudimental state. The Lepraria are sometimes referred to Byssaceae, but they seem to be the commencing point of the organization of true lichens. They have a thallus resembling a scurf which is formed from spores. They are very common on decaying timber of all kinds.

The cells of the leaves of many plants during decay assume a variety of forms which have been described as cryptogamic plants under the genera Phyllostrium, Erinaceum, Gynopopodium, Topharia, Tophus, &c. Many of these so-called plants are meteoric productions; ‘on one occasion they are said to have suddenly overrun all the leaves of pines on the side next the wind in the neighbourhood of Dresden; on another, on the 10th of August, 1830, to have spread over the sails and masts of a ship at Stockholm; and Fries is disposed to consider the cobweb-like matter that overruns the grass in the mornings of spring and autumn of this nature, and not of animal origin.’ (Lindley.)

Note.—Since the article Bawren was printed off, two or three errors have been pointed out by one of his pupils. In line 5 of the article, for ‘off mi town,’ in col. 2, line 11, read thus: ‘In 1797 Thomas published the first volume of his “History of British Birds”’ and add, at the end of the paragraph, ‘The second volume was published in 1804.’ In col. 2, line 18, for ‘by his son Robert and other able pupils,’ read ‘by his pupils.’ Robert was not engraver on wood. In col. 2, line 28, for ‘and his “British Fishes,”’ read ‘and vignette for his “British Fishes,” which work was never published.’
CAB, or CABRIOLET. [HACKET-COACH, P. C. S.]

CA'CCIA, GUGLIELMO, commonly called MON- 
CALVIO, born from Moncalvo in Piedmont, was 
born at Montabone in 1568. He was one of the best 
provincial painters of the seventeenth century, and is one of 
the most celebrated of the Piedmontese painters. There are 
still several of his works in Milan, Pavia, Turin, Novara, 
Moncalvo, Casale, and other cities of that province. The 
church de' Conventuali alone, at Moncalvo, contains almost 
a gallery of Caccia's works in oil; they are very light in 
colour, but faint in effect, and in design frequently remind us 
that they were executed by Bernardino Campi, another of his 
brothers, and are also superior to that art, notwithstanding that 
Holy Families and such pieces. He is reported to have 
studied with the Carracci, a fact which Lanzi considers very 
probable, and he says that if Caccia studied in Bologna at 
all, it must have been from the works of L. Bartolini, prior 
to the Carracci; but he accounts for his similarity of style 
with that master, from a picture by Soleri in Ca’sele, from which 
he may have acquired it, as their styles are very similar. 
Bernardino Campi also painted in a very similar style. Caccia's 
best works, being copies of those by his brother, were executed 
at Milan, and in San Paolo at Novara. His masterpiece in oil 
is considered the Deposition from the Cross, in the church of 
San Gaudenzio at Novara: there are also two excellent altar-
pieces by his brother, in the same church at San Gaudenzio; for such 
works Caccia set up at Turin, and two others in a chapel of San 
Domenico at Chieri. Some of his landscape backgrounds are in 
the style of Paul Bril: he died about 1625.

Caccia instructed two of his daughters in painting; Osola 
Maddalena and Francesca, by whom there are many works in 
Moncalvo and the vicinity: the pictures of the elder, Osola, 
are marked with a flower; those of Francesca with a bird. 
Osola founded the Conservatorio delle Orelle (Urasilina) 
in Milan, and lived there till she was about twenty years 
older: she died aged fifty-seven.

Orlandi, A. Barcelli, Bellori, Lanzi, Storia Pittorica, &c.

CAGNOLLA, LUIGI, the most distinguished Italian 
architect of the present century, his fame having been 
extended through Europe by his most celebrated works in modern 
times, the magnificent Arco della Pace at Milan, was born in 
that city in 1769, of an antient patrician family, one of whose 
ancestors, Aripandro Cagnola, was consul of Milan in 1117. 
At the age of fourteen, Ioliet was sent by his father, the 
Marchese Gaetano Cagnola, to the Clementine College at 
Rome, where he applied himself entirely to the study of 
architecture, in consequence of the impression made upon him by 
the ancient edifices of that city. On being recalled home, 
he was sent to the university of Pavia in 1781, in order 
to study jurisprudence; but, although he was so far from 
neglecting his studies that he obtained honorary prizes, his 
passion for architecture was insuperable, and he resolved to 
devote himself exclusively to that art, notwithstanding that 
professional practice in it was deemed somewhat derogatory 
in one of his rank and station. In this determination he was 
confirmed by finding that a better taste in architecture was begin-
ning to prevail at Milan, where it had been introduced by Pier-
marini [Piémart, P. C. S.], Polacchi, and Cantoni [Cas-
toni, P. C. S.].

Cagnola at first accepted some official post under Count 
Willez, then governor of Milan, but did not continue in it 
in a provincial capacity, by the high rank of his father, to 
take upon himself the chief management of the family affairs. 
After that he filled for two years the office of Viro Probo, a 
sort of alevship in the civil government of Milan. At that 
period he ventured to put to the test three designs for the 
Porta Vercellina, but the two upper were rejected at Milan, and of which Pier-
marini had been appointed architect by the Archduke Ferdi-
nand, at that time governor of the city. At the archduke's re-
quest Cagnola's designs were submitted to him; yet, though 
the two upper were approved, that by Piermarini was adopted, as being 
more economical. He now engaged the services of a very clever 
perspective draftsman and water-colour artist, Ugo Auleggio, 
and undertook a series of illustrations of the ancient baths of 
Maximilian at Monza, called, at the instance of Antichith Lombardico-Milanese; and he was 
appointed by the government (1812) to secure 
from further ruin the sixteen noble Corinthian marble columns 
which constitute the chief remains of that monument of 
antiquity. The death of his father, in 1795, devolved upon 
Cagnola an important station in public life, when he was 
being one of the state council, he was attached to the army-
commission in the Austrian service, which office he dis-
pached with prudence as well as ability. On the change 
of the government by the establishment of the Cisalpine Republic, 
having withdrawn from the Austrian service, he went to 
Venezia, where he found sufficient and congenial 
opportunity in studying the architectural treasures of those 
cities. Soon after his return, he erected in 1802 a noble 
villa at Milan, and the brothers of the Societa de' 
Giovanni were employed to the works, when it was 
progress was nearly destroyed by an earthquake that did great 
damage throughout the district; but he repaired the mischief 
done to the works with so much skill and promptitude as 
thereby to acquire increased fame. It was about the same 
period that he designed the magnificent catafalque for 
the funeral obsequies of Archbishop Vincenzo, the Patriarch Gamberi, and Count Anguissola, published in folio, 1802. On 
the marriage of the Vicerey Eugenio Beauharnois with the Princess 
Anemone of Bavaria, he was commissioned to design and 
execute another grand temporary structure, which, like the preceding 
one, would now be known only by engravings, had it not 
prevented the Rovigo to be his most celebrated achievement in 
his later years. Cagnola's designs were all constructed of 
wood on that occasion, it was determined to perpetuate it in marble. Accordingly, the first stone of the Porta 
del Seminario, for, as it is now called, the Arco della Pace, 
was laid October 14, 1807. The political changes which 
 afterwards took place threatened to put a stop to the work alto-
er, when it was not advanced beyond the piers of the arches.
Almost the idea of its being ever completed had been 
abandoned; when, on his visit to Milan, the late emperor (Francis 
I. of Austria) resolved the work to be resumed; and from 
that time they were prosecuted without interruption, so that 
Cagnola saw the whole structure terminated, or very nearly so, 
before his death, exclusively of some of the decorative sculpt-
ure and bronze figures. With the single exception of the 
arch de' Enotri at Paris, the Arco della Pace is by far the 
largest as well as most magnificent structure of the kind 
in modern times, and in its general mass it is equal to, even if 
it does not somewhat exceed, the largest of the ancient—
the Arch of Constantine; it is 78 feet wide and, as many 
high, and about 27 feet deep.

Another public monument by him at Milan, which is 
greatly admired, is the Porta Ticinense, an Ionic propylaeum, whose two fronts 
consist of a distyle in antis, consequently of three open inter-
columns, and the two sides or ends are filled in with an open 
arch. Nothing can be more simple or even severe in character 
than this structure, for it is one of the very few things in 
Italian architecture which decidedly approach the style 
of Grecian antiquity; but not even the desire of novelty could 
induce Cagnola, any more than the rest of his countrymen, to 
shake off his allegiance to Vitruvius and Palladio. Compared 
with Athenian examples his Ionic capitals look meagre and 
insignificant, and seem at all events to require a necking, which, 
by adding to the mass of the capitals, would have reduced 
the lankness of the shafts.

The Campanile at Urgnano in the Bergamasca territory, 
begun in 1834 and finished in 1849, he was called upon to 
execute the design and composition than the preceding. It is a circular tower of three 
orders, Doric, Ionic, and Corinthian, upon a square rusticated 
basis, each order consisting of eight half-columns, and 
between those of the Corinthian order are as many intermediary 
columns, and the two sides or ends are filled in with an open 
arch. Nothing can be more simple or even severe in character 
than this structure, for it is one of the very few things in 
Italian architecture which decidedly approach the style 
of Grecian antiquity; but not even the desire of novelty could 
induce Cagnola, any more than the rest of his countrymen,
CAL is not specified. The interior had sixteen columns of the same order. Besides those which were carried into execution, Cagnola produced a great number of designs and projects, in several of which he gave such free scope to his invention and grandezza of ideas, as to render their adoption hopeless; such, for instance, was that for an Hospital on the summit of Mount Cenis, with no fewer than one hundred and ten columns, eleven English feet in diameter—whereby it may be added his designs for a senate-house and a magnificent triumphant bridge. In fact, he derived no insuperable share from his celebrity: from his designs of that kind; wherefore it is greatly to be regretted that he neither edited them himself, nor directed by his will that both they and those of all the buildings he executed should be given to the world in the form of a general publication of his Gifts, with a memoir of that would have made them universally known. However, he indulged his taste without regard to cost in improving or nearly rebuilding his villa at Inverigo near Milan, which occupied him during the last years of his life, and which he directed to be completed by his widow. One noble interior feature of this palatial villa is a magnificent central rotunda erected on what was originally an inner court. Cagnola died of apoplexy, August 14th, 1833, at the age of seventy-five, and is a portrait of him in his 'Beitrage' for 1838, with an accompanying memoir, to which we are indebted for some of the particulars in this article. Among those of Cagnola's pupils who have since distinguished themselves are Peverelli, Bianchi (architect of the church of San Pasquale da di Naple), Vergani, Galiardi, and Dordonce. CAKILE, a genus of plants belonging to the natural order Cruciferae, to the suborder Lomatuceae and the tribe Cakilinae. It is a monotypic genus, and the tribe, it has an angular pouch composed of two 1-seeded indehiscent joints, the upper joint deciduous with an erect seed, the lower one persistent, seedless, or with a pendent seed. The species are smooth, fleshy, glaucous, annual branched herbs, with pinnately compound leaves. For the species opposite the leaves, and terminal with silicaceous bracteole petals. C. aralis, Purple Sea-rocket, has the joints of the pouch 2-edged, the upper one with two teeth at the base, the leaves entire, pinnate, somewhat toothed. The flower tube is of a purplish colour. It is a native of Europe, along the sea-coast from Sweden and Lapland to Gibraltar: it is also found on both sides of the Mediterranean. It is a native of Great Britain, on the sea-coast. This plant had at one time a reputation as a cathartic, but it is not employed at the present day. There are three other species of Cakile named as: C. Euphytis, C. Americana, C. equisata. They are all pretty annuals, and may be easily cultivated. The seeds may be sown in spring or autumn, and they should be treated as other hardy annuals.

(Babington, Manual; Don, Gard. Dict.)

CALYDUM, a genus of plants belonging to the natural order Araceae, and to the tribe Caladiinae. The flowers are monoecious, the pistil and stamens. The flowers have many-celled peltate anthers, disposed in a spike at the end of the spadix; the female flowers have the ovaries inserted at the base of the spadix, no style; the fruit is a 1-celled berry with many seeds. A great number of species of this genus have been described. They are frequently cultivated in this country for the sake of their spotted stems and next green leaves, which are rarely disfigured by any of the accidents which affect other stave-plants. They have the same uses as the species which belong to the Arum, and also resemble them in physical and chemical properties. C. Seguinum, Dumb-cane, is a caulescent suberect plant with oblong capitate leaves, and the spadix shorter than the oblanceolate leaves. This plant is a native of South America and the West Indies. It grows to a height of five or six feet. It secretes an acrid poison, so that when any part of the plant is chewed the tongue swells and the power of speech is lost. It is in this account called Dumb-cane. Sir William Hooker, in his 'Flora of New Zealand,' has compared the caule with a painter who has ti

CALAMIS, a very celebrated Greek sculptor, of the fifth century before Christ. Neither his native place nor the exact period of his career is known; he was however contemporary with Phidias, but probably his senior in years, as according to Cicero and Quintilian, who probably expressed the general opinion, notwithstanding the general excellence of his work, he was the first craftsman in Rome who undertook the whole work of a temple. He was of various styles, in marble, bronze, and ivory, and as an engraver in gold. He was also very famous for his horses, in which, Pliny says, he was without a rival.

Most of his works by Calamis are mentioned in ancient writers, Greek and Latin; but one in particular claims attention. This is the Apollo of the Servilien gardens at Rome, mentioned by Pliny, and by some supposed to be the Apollo Belvedere of the same name which abacus similarly completed sets aside the criticisms of Cicero and Quintilian as to the style of Calamis, for this work, so far from being hard, would be effeminately delicate for any male character below a divinity.

Calamis made two other statues of Apollo: the Apollo Alemisthakos (Deliverer from Evil), which Pausanias saw at Athens; and the colossal Apollo, made for the city of Apollonia in Illyricum, and which, according to Strabo, was brought to Rome by Loculus, and placed in the Capitol. Juinus and Harduin supposed that Pliny and Pausanias speak of the same work; but it is not at all probable that a work which was in Rome in Pliny's time would be in Athens in the time of Pausanias. This inconsistency has been pointed out before; but they have been maintained by the opinion, and it seems to have suggested the idea which Visconti and Flixman have adopted, that the Apollo Belvedere and the Apollo Alemisthakos of Calamis are the same, or at least that the former is a marble copy of the monumental Calamite which is supposed that the same situation mentioned by Pausanias must have been of bronze, because it was placed in the open air; this does not follow however, as many of the ancient Greek marbles were placed in the open air. It was dedicated in honour of Apollo after the delivery of Athens, in Ol. 87, 4 (429 B.C.), during the Peloponnesian war. It is the latest work by Calamis mentioned, and must have been made at least three or four years after the death of Phidias. His earliest altar was a cylinder-shaped altar mounted by boys, for the triumphal car of Olympus placed by Deinomenes, the son of Hiero, at Olympia, in Ol. 78, 3 (467 B.C.), in commemoration of Hiero's victory at the Olympic games, twelve years after the battle of Marathon.

Lucian also, in his description of Panthæus has recourse to the aid of Calamis. He takes some of Panthæus's charms from a statue of Sosandra by Calamis, which he mentions also in his "Heteræan Colloquies" as a paragon of beauty. Many other works by Calamis are mentioned by ancient writers, such as Col. Cæs., Victores, Eligius, Baccius and a Mercury at Tanagra, a Venus at Athens, Jupiter Ammon at Theba, Hermione at Delphi, &c. (Pliny, Hist. Nat. xxxii. 12; xxxiii. 8; xxxvi. 4; Pausanias,iii. 19, 20; Vitruvius, vii. 3, 4; Calamites, 18; Quintilian, Inst. Orat., xii. 10; Strabo, vi; 491; Juinus, Catal. Artifices; Sillig, Catal. Artifices; Thiersch, Epochen der Bildenden Kunst, &c.)

CALAMITES, one of the most frequent and characteristic genera of fossil plants. It is found abundantly, but not exclusively, in the carboniferous system of strata, and generally in the sandstones and shales which alternate with coal. Calamites Buckovi occurs in most European and American coal measures. We have found traces of a calamites in the red marl series of Worcestershire.

CALAMITES: (Coal-plants, P. C.)

CALAMO/pora, the generic title applied by Goldfuss to many Palseacine corals, for which of which Lamarck employed the name of Favosites.

CALCAIRE GROSSIER, the coarse calcareous building-stone of Paris, which, geologically speaking, is coeval with the clay of those of London, and contains many identical shells. These constitute the types of the Eocene tertiary series of Mr. Lyell.

CALCICOLIA, an extinct genus of Brachiopoda, which occurs in the Palseacine strata, and especially in the midlithon of the Salamanca sandstone. The shells of the Pausanias sandstone and in the Eifel and in South Devon.

CALCULATING-MACHINES. Before computers had attained great proficiency in performing arithmetical operations in the pen, machines by which the results of such operations could be obtained by inspection were in almost constant use: the Roman abacus, which continued to be employed in the south of Europe till the end of the fifteenth century, and, in England, to a later period, consisted of counters moveable in parallel grooves or on parallel wires, and having the different denominations units, tens, hundreds, &c., according to the grooves in which they were placed. Thus a counter in the first groove represented 1, while a counter in a groove corresponding to it represented 5; and a counter in each of these expressed together 6. A counter in the second groove denoted 10, while one in a groove corresponding to it denoted 50, and one in each expressed together 60; and so on. The Romans had also machines of the like kind which were applicable to duodecimal arithmetic. The form and use of such machines is thus described under ABACUS, P. C. An account of the arithmetical rods invented by Napier for the performance of arithmetical operations is given under NAPIER'S BONES, P. C.; the nature and use of the logarithmic scales, under SLIDING RULE, P. C.; and under SANDIFERSON, P. C., is a short account of the machine invented by that mathematician for enabling the blind to make computations.

The celebrated Pascal constructed, it is said, when only 19 years of age, a machine for executing the ordinary operations of arithmetic; and as it has a resemblance, though slight, to the machine invented by Mr. Babbage, it may be proper to give a brief description of it in this place.

It was an assemblage of wheels and cylinders, and on the convex surfaces of these were the numbers by which the operations were to be performed: these operations consisted chiefly in the addition and subtraction of sums of money having the denominations of livres, sous, and deniers, for which may be substituted periods of shillings, and pence, and to those denominations the numbers were adapted. Extending round the convex surface of the first cylinder on the right hand of the machine, and one above the other, were the two series.

0, 1, 10, 9, 8, 7, 6, 5, 4, 3, 2, 1
0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10;

the first of which served for the subtraction and the other for the addition of pence; the cylinder being turned in the same direction for both operations. Upon the surface of the next cylinder, on the left, were the two series.

0, 19, 18, 17, 16 . . . 1
19, 0, 1, 2, 3, 4, 5, 6, 7, 8,

serving for the like operations on shillings: and on the left of this last were several cylinders, about each of which were the two series.

0, 9, 8, 7, 6, 5, 4, 3, 2, 1
9, 0, 1, 2, 3, 4, 5, 6, 7, 8,

and these were used for operations with pounds, or with any numbers in the series.

Attached to the axes of the first cylinder was a wheel having on its circumference 12 teeth, on that of the second, one having 20 teeth, and on the axe of each of the other cylinders was a wheel with 10 teeth. When the operation commenced, the zeros of the numbers in the first or second series above, on all the wheels, were brought by hand to the front of the machine.

As an example of the method of using the machine, let it be required to add together the following sums of money:

£ 8 9s. 6d.

Be means of a pointer the wheel connected with the first cylinder on the right is to be turned till the eighth tooth, and after it the number of the cylinder is brought to the front; in like manner the number 9 on the second cylinder and 8 on the third are brought to the front: thus the series of numbers in the fronts of all the cylinders exhibits the first of the above sums of money. Then, by means of the pointer, the first wheel and cylinder on the right hand are to be turned till the sixth tooth (after the eighth) comes to the front, when the cylinder having, from its first position, performed on its axe one revolution and 2 operations on its axle one revolution and 2 of another, the number

2

2, representing 12-4, or 1s. 2d., appears in front. Now, the construction of the machine shows that the revolution of the first wheel and cylinder on the right hand causes the wheel and cylinder on its left to turn one-twentieth part of a revolution; by which means, in this example, the number 9 being already in front of the latter cylinder, the number 10 is now there: thus the one shilling obtained by the addition
The machine accomplishes these additions by the movement of a number of cylinders having on the convex surfaces of each the series of numbers 1, 2, 3, 4, 5, 7, 8, 9, 6; and the operations are thus distributed: by the first, the additions are made; and by the second, this is increased, which should be carried to the ten's place every time that the sum of two numbers is greater than 10.

Let it be imagined that there are several vertical axles, each of which are several cylinders one above another; at that the machine is operated, the cylinders are turned by work-wheel, so that any one of the ten figures may be made to stand on the face of the machine, and immediately under a fixed index. Let it be further imagined, that, with the above axles, the second machine (the hand or wheel of a winch) has made one quarter of a revolution, the first, the fifth, &c. axles may turn, causing the cylinders on them to make parts of a revolution or allowing them to remain at rest. The case may be, while all the cylinders on the same, fourth, &c. axles remain at rest. Again, when the moving power has made the second quarter of a revolution, let it be imagined that one, only, of the cylinders on the first, third, fifth, &c. axles make one-tenth of a revolution, so that whatever figure be under the index of each of these same cylinders, the next figure, in increasing order, may be brought under that index, the cylinders on the second, fourth, &c. still remaining at rest. Let it then be imagined, that, when the moving power describes the quarter of a revolution, the cylinders on the second, fourth, &c., are made to move described as a revolution or remain at rest, the cylinders on the other side being unmoved; and lastly, when the moving power is described the fourth quarter of a revolution, let certain cylinders only, on the second, fourth, &c., make a revolution, the other cylinders remaining at rest. The it may be understood that by the first and third of these names, numbers are added together; while, by the second and fourth, 1 is carried to each figure which ought to be increased a consequence of a sum of two figures being greater than 10.

As an example, let it be required to obtain the number in the series in the first column above, beginning with 3125.

Let the figures composing the number be under the index in front of the cylinders on the first vertical axis, towards the left hand; and the figures composing the several orders of differences in front of the cylinders on the other axis, towards the right, as in this second table. Then the moving power being turned one quarter of a revolution, each cylinder is the first, third, and fifth vertical columns will be turned through as many tenths of a revolution as are expressed by the order of the number in front of its own column. Thus, if the cylinder having 3 in front (at the top of the first vertical column) will move through four-tenths of a revolution, and the number 7 will be brought under its index in front. The cylinder having 1 in front (in the first vertical column) will be turned through six-tenths of a revolution, which will bring 7 under its index in front; and so on.

The numbers in front of the whole machine will now stand thus:

Now it is evident that, having any one of the numbers in the first column, and the number corresponding to it in the second column of differences; all the succeeding numbers of the series may be found by more additions. It may happen however that, in the vertical column of the original cylinder, the numbers in some of the columns of difference may decrease; and then, in forming the terms of the series, subtractions might take place: in such a case, the arithmetical comprehension and calculation to be made, being in the order of a revolution, the cylinders on the second and fourth axis by the addition (in the preceding table) of 6 in the third column to 8 in the fourth, there should be produced 14, whereas 8 only appears under the index of the cylinder (the third column of the present table), therefore 1 must be carried. The operation of carrying is performed by the action of the moving power in the second quadrant of its revolution; and, in the present example, this does not move the cylinder having 8 in front (at the top of the first vertical column) through one-tenth of a revolution, which brings 4 to the front of that cylinder. The reader may now imagine the 3 to be effaced, and the number 4 introduced in its place. No further operations being necessary, the machine having being turned one quarter of a revolution, the cylinders on the second and fourth axis
are made to turn through as many tens of a revolution as are expressed by the figures on the cylinders immediately on their right hand; these figures on the cylinder marked $a$ in the second column of the last table will turn through four-tenths, and this movement will bring to its front the number 8; the cylinder marked 6 will be turned through three-tenths of a revolution, which will bring to its front the figure 9, and so on.

The numbers in front of the machine will now stand thus:

<table>

The moving power turning through the fourth quadrant will perform the operations of carrying; and, in the present example, the cylinder marked 9 will turn one-tenth, which brings 0 (for 10) to its front; this causes another carrying, and the cylinder marked 8, in the same column, will turn one-tenth; which brings 9 to its front. The cylinder marked 1 in the fourth column will turn one-tenth on account of the carrying from the cylinder 5 below it, which brings 2 to its front; and the machine will stand thus:

The operation is now completed: the number succeeding 3155 in the series is 7776; and the like operations being performed with the instrument in the present state, the next number will be obtained in the first column. It has been supposed that the instrument has only six axles carrying cylinders; but it is evident that, if a number consisting of more than four places of figures were given, or were to be produced, a greater number of axles would be necessary.

We have it not in our power to do more than give the following very general notion of the mechanism by which these remarkable movements are produced. Immediately behind each column of the cylinders $D$ carrying the figures, and in a vertical plane perpendicular to the front of the machine, is a vertical axle $X$ which carries, opposite to each cylinder, two small iron wheels $A$ and $B$, and between them a movable bolt $C$, also in a horizontal position: these two wheels are capable of being connected with or disconnected from the axle, so that they may or may not turn with the latter. The upper wheel $A$ is furnished with teeth, standing out horizontally from the rim, and these work in the like teeth formed about the cylinder $D$ carrying the figures, so that the wheel $A$, when it turns with its axle, may be said to drive the cylinder. It is also furnished with teeth which it turns perpendicular to its lower surface in the manner of an inverted crown wheel. The bolt $C$, which is under this wheel, and passes through the axle, is capable of being moved a short distance horizontally; it is provided, near its extremity, with a pin or tooth $a$ standing perpendicular above its upper surface, and with a pin $b$ perpendicular below its inferior surface. And the lower wheel $B$ carries a wedge or inclined plane $c$.

Behind the wheels on the axle $X$ is another axle $Y$, which is also in a vertical position: this carries a projecting bar or point which revolves around the center of the machine to turn by the action of the moving power. During its revolution, it meets, at a proper place, one extremity of a lever $a$ which is capable of turning on a pivot at $p$: that extremity being displaced, the extremity of the opposite arm presses against the end of a bolt $C$ in the cylinder $D$ and causes it to turn on its proper axis $Z$. Such is the nature of the mechanism that, while the moving power describes the first and the third quadrants of its revolution, the cylinder $D$ might make a complete revolution; but, in general, the cylinder is to make only as many tenths of a revolution as are expressed by the figure in front of the next cylinder on its right hand; and therefore the bolt is to be withdrawn from the crown-wheel when such part of a revolution has been performed. This is accomplished by the pin $b$, which, moving along the wedge or inclined plane $c$, draws the bolt back so that the pin $a$ above is removed from between the teeth of the crown-wheel; the latter is thus disengaged from its axle and ceases to revolve: at the same time the cylinder $D$, with which it is connected by the teeth of its horizontal axis, continues to revolve.

The cylinder remains then at rest till it is moved at a subsequent step in the process. If the cylinder is not to turn while the moving power describes the first and third quadrants, an apparatus provided for the purpose removes out of its place the lever which should press against the end of the bolt.

For every vertical axle carrying cylinders in front of the machine, there is an axle carrying wheels and bolts, and an axle carrying the fingers which lock the bolts: and behind every cylinder is its proper apparatus, consisting of wheels, bolt, and finger.

The process of carrying, which takes place when the moving power is describing the second and fourth quadrants of its revolution, is accomplished thus:—the lever or finger revolves on the axle of the lowest cylinder $D$, for example, in the first vertical column on the left; and, at a proper time, comes against the extremity of a claw which then engages itself between the teeth of a ratchet-wheel connected with the next cylinder above it; both the wheel and cylinder are thus made to turn, but the length and position of the claw are such that the cylinder can only make one-tenth of a revolution, and thus bring to the front a figure greater by unity than that which was there before. When a cylinder has made the movement just indicated, a projecting pin, called a thumb, on the axle of the lower cylinder, touches a trigger which raises, out of a notch in the claw, a hook which retained the latter: a spiral spring then draws back the claw; and the bolt, with the teeth of the ratchet-wheel without creating any movement in the cylinder; and the apparatus is thus prepared for the next carrying operation which is to take place.

A very ingenious contrivance is also provided in order to produce an equalization of the action through the machine during an operation: this consists in having the fingers by which the bolts and claws are moved placed spirally on the several axles, so that they do not act during the time that the moving power describes a quadrant of its revolution: and the fingers which cause the bolts to enter between the teeth of the crown-wheels are disposed so that the shooting of a bolt may take place immediately after the obstruction of the finger by which the carrying is accomplished. The carrying process, by which means a carrying is allowed to take place when the previous process of carrying has already caused a cylinder, in moving one-tenth of a revolution, to bring 9 (for 10) to the front.

The most remarkable circumstance in this machine is the provision which may be made in it for avoiding errors arising from inaccuracies in the original construction, or from accidental derangements; but as the means of obtaining this end have not yet, we believe, been put in execution, nothing can be said concerning them.

It is proposed by the inventor to apply to the machine an apparatus by which the numbers obtained from the cylinders in the left-hand column may be immediately reduced by proper operation of the apparatus to plates of copper, in order that the results given by the machine might be printed without a possibility of error. A curvilinear bar of metal is to act on an arm of a lever so as to raise it to ten different heights corres
responding to the ten figures on the surface of a cylinder; and the opposite arm of the lever is to move an arch carrying two needles, one having on them the characters 1, 2, 3, &c., in relief. The plate of copper being below, a bent lever is to press the punch upon the plate, and produce the impression of the figure. The different figures in front of the first column of cylinders are supposed to be indefinitely transferred to a copeplaque; and the arch and plate being shifted, the set of figures brought in front of the cylinders in the same column at the next operation with the machine, may be transferred in like manner.

Note: Be aware that the cause that the construction of this superfluous machine is suspended, the circumstance cannot fail to be a subject of great regret. The portion which has been already executed is now in the library of King's College, London; and the machine is noted that it is capable of producing any number of cylinders, and the powers and roots of numbers not exceeding beyond eight places of figures.

A great improvement on the machine above described is contemplated by the inventor; who, with reference to the purposes to which the improved machine can be applied, designates it an Analytical Engine. In Taylor's 'Scientific Memoirs' (vol. iii. art. xxi.) there is given, by M. Menabrea of Turin, a sketch of the properties of the engine; and in the same 'Memoirs' by the Translator of the above-fortune paper is the following summary of the operations which can be performed by it:

It will perform the several operations of simple arithmetic on any numbers whatever. It can combine the quantities algorithmically, especially in an arithmetical analysis. It can use algebraic signs according to their proper laws, and develop the consequences of these laws. It can arbitrarily substitute any formula for any other, effecting the first transformation of the second, and making the second appear in its stead. And lastly, it can effect processes of differentiation and integration on functions in which the operations take place by successive steps. It is further stated that the engine is particularly fitted for the operations of the combinatorial analysis, for computing the numbers of Bernoulli, &c.

C A L D E R A R I , O T T O N E , a nobleman of Vicenza (where he was born in 1750), to whom that city is indebted for many important public works, especially for the building of the Palazzo Dal Zoppo, or of any of his buildings either at Vicenza or elsewhere, although he is rather particular in his notices of those by Palladio in that city: neither does Wightwick in his 'Sketches by a Travelling Architect' (in 'Library of Fine Arts,' 3 vols., 1820) mention a building in his 'Architectural Encyclopedia' Gwilt preserves the same complete silence, neither inserting his name in the list of architects, nor the large and beautifully executed folio work of his 'Designs' in that of architectural publications. The only testimony to the merits of Calderari which we have met with in any English publication, excepting Creasy's translation of Milizia's 'Lives,' is in a paper in the Quarterly Review, No. 2, on the Palladian Architecture of Italy, where it is said: 'One of the most eminent architects of that school is the celebrated Calderari. His name is particularly distinguished for his simplicity and elegance, and his knowledge of the true principles on which the beauty of Grecian (Greco-Italian) architecture depends. The Loschi and Besaro palaces at Vicenza, and the Basilica at Verona, are noble specimens of his skill'—and likewise of his taste.

Instead of apologising for remarks that will at all events not diminish the interest of this notice, we have to regret that scarcely anything amounting to biography can be collected from the works of Calderari. His name is not the subject of any biographical sketch. No reference is made by any of the editors of his 'Designs,' in the 'Eloge' prefixed to that work, where he styles him 'Il Immortale Calderari.' His enthusiasm for architecture is said to have been first excited by viewing the Basiliica of Vicenza by night, which made so powerful an impression upon him that he therefor devoted himself to the study, and became, like Burlington, more than a mere 'dabbling amateur' in it, since his renown eclipsed that of many of his professional contemporaries. One of his earliest recorded works was the casino erected by him near Vicenza, in 1772, for the Count Anti-Sola, which has a very extended front towards the gardens, with terraces leading from the house to the wings. In 1773 he built the small Palazzo Bonini at Vicenza, whose façade has two orders, Doric and Tonic (of five intercolumns), surmounted by an attic, and so arranged as to deserve the admiration of every inquisitive mind. In 1776 the Casino Too, and also the Palazzi Quinto and Salvi, in the same city. Nor was Vicenza alone the scene of his architectural labours, for he designed the beautiful atrium of the Seminario at Verona, and the Villa Cayra, at Marano, and the Casa Cozzolani in the Mantuan territory.

Count Calderari belonged to the principal academies and societies in Europe, and was elected by the French Institute, London, to a chair of architecture. He was expressly invited to come over to France; and it was then clearly intimated that it was his last wishes so to go. This project was, however, never carried into effect; and in 1781 he died, at Vicenza, January 22nd, respecting which date, nor can it be denied that he is entitled to be considered as the admiration of those who hold Palladio to be a pattern of excellence. He died at Vicenza, October 26, 1803, and his will was pronounced by Diedo, secretary to the Academy of Fine Arts, on the 18th February, 1804. His tomb stands in the 'Cimitero,' and has the dates 1750 and 1803. The portrait of him prefixed to that work, there is one in Gamba's 'Galleria de Letterati,' &c., Venice, 1824.

C A L D E R A R I , OTTON E. (vols., 1820), 'Architectura,' &c. 2 vols., folio, 1808-17. Though there is no portrait of him prefixed to that work, there is one in Gamba's 'Galleria de Letterati,' &c., Venice, 1824.

The common smoothing-iron affords the simplest illustration of the process of calendering, and the mangle, which is so frequently employed as a substitute for the smoothing-iron, presents another, the operation of which is identical with that of the earlier calender or calendering machines, in the common mangle, as in the old calenders constructed on the same principle, the cloths to be smoothed are rolled upon smooth wooden rollers, and laid between two hard flat surfaces, the lower one of which is immovable, while the upper, which is formed by the bottom of a large box, is capable of being moved backwards and forwards in the direction of its length, thereby causing the cloth-covered rollers to roll backwards and forwards until every part of the cloth wrapped upon them has passed over the rollers. Though the action is the same, the alternate motion of the pressing-box, which is usually loaded with stones, is produced by turning a winch-handle, which alternately winds and unwinds ropes extending from the ends of the box to a drum or cylinder fixed over it. To establish this nomenclature, in his 'Travelling Architect,' in the direction of the motion required, various ingenious devices have been resorted to, by which the alternating motion of the loaded box is produced by a continued motion of the winch-handle in one direction, by moving larger and heavier than common mangles, the old calenders made on the same principle were often worked by a horse-wheel, or some other moving power. The process of calendering was greatly improved by the invention of a machine in which the pressure is produced by the combined action of a cylinder and flat surfaces, and in which, consequently, the alternating motion is got rid of; and, also, it is easier to give a uniform and equal pressure. According to the writer of the article 'Calendering' in the 'Encyclopædia Britannica,' the cylindrical calendering engine was introduced into this country from Flanders and Holland by the Huguenots who were driven to England by persecution. The rollers or cylinders were formerly made of wood; but, as it was found impossible to combine an iron calender with a wooden frame, they are now usually made either of paper or of cast-iron. The paper cylinders, which form the most remarkable feature of a modern calender, are formed in the following manner. The axis of the cylinder is a strong metal rod, and the body of the cylinder consists of a great number of circular pieces of stout pasteboard, each of which has a square hole in the centre to receive the axis, and six smaller round holes at equal distances from each other, near the periphery, A
Kensington, This belongs, his and immediately Propter rather Calen- found He wrought-iron, composed weighted-native

bale, it is a native of these islands, and has been introduced from the south of Europe. This plant is a great favourite in gar- dens, and continues to blossom till the approach of winter. It is often grown in churchyards in this country, and in France, but this plant does not appear to be connected with any superstition. There are various varieties of this plant found in gardens, as the orange-coloured, the lemon-coloured, and the double. It formerly had numerous virtues attributed to it, but independent of the bitterness of the tribe to which it belongs, and a rather more powerful volatile oil than is found in other species of the order, it possesses no active properties. The flowers are used in some parts of the country to give a yellow colour to cheese. In

The Clock of Flora Linn. is set ten in the morning and to close them at three in the after- noon. C. pluricola has been named from its flowers closing at the approach of rain. The petals of these plants are some- times employed for marking the saffron.

(Calendula, Encyclopedia of Plants; Koch, Flora Germanica.)

CALLCOTT, JOHN WALL, one of the brightest orna- ments, in every sense of the term, of English Music, was born in 1765, at Kensington, where he had carried on a business of a builder. At the age of seven he was entered as day-boarder in a neighbouring school, where he made such progress that he commenced reading the Greek Testament in his twelfth year. He afterwards, by the supersti- cion of his removal, from which time, great and various as were his requirements, he was self-educated, a circumstance to which, probably, the vigour of his unshackled mind may be ascribed. Miss Haydn, his aunt, who, in the meanwhile, had come his profession, instead of surgery, for which he was pre- pared to qualify himself, when the sight of a severe operation so powerfully acted on nerves of remarkable sensibility, that he at once abandoned all hope of succeeding in the healing art, and devoted himself to that of harmony, the study of which he prosecuted without any master; though by a con- stant attendance at the Chapel Royal, at Westminster Abbey, and many concerts, together with the friendly hints, given in the wide universe, by Drs. Cooke and Arnold, he, no doubt, profited very largely.

He commenced his professional career in the subordinate capacity of deputy-organist of St. George the Martyr, Queen Square; and at about the same time made his first attempt in the composition of church music. His first attempt, the Gloria in excelsis, in 1755, when only nineteen years of age, he appeared as a can- didate for the prizes annually given by the Catch Club, and obtained three out of the four gold medals. Among the suc- cessful pieces was that, latterly composition. 'Oh! sovereign of the willing soul.' Thus encouraged, he followed up with ardour and industry the course so auspiciously begun, and in the following ten years, twenty medals of the same most distinguished and laudable character were awarded to him. We may, however, add, that some of his best productions were either not candidates for prizes, or unduly appreciated by the dispensers of those musical honours.

In 1785, at the early age of nineteen, Mr. Callcott was elected by the University of Oxford. In 1787 he assisted in forming the Glee-Club. In 1790 he took advantage of the arrival of Haydn in this country, and de- rected considerable knowledge in the higher branch of instru- mental music from that illustrious musician. He ad- vanced to the degree of doctor-in-music at Oxford, in 1790; his exercise was a Latin motet, selected from Isaiah, beginning "Propter Sion non tacebo." His 'Musical Grammar' ap- peared in 1806. About the year 1808 he began to deliver lectures on music at the Royal Institution, a task to most of all others suited to his studies and gratifying to his ambition: but the very anxiety he felt to execute the duty in a manner worthy of himself, rendered his hopes futile, and his efforts unavailing. His mind, too, overworked, and under the burthens he had so unsparingly laid on it, and he became incompetent to the fulfilment of any of his engage-
menta.' After a succession of five years, he rallied for a time, and by avoiding all severe study or exciting occupation, afforded hopes to his friends that his mental powers were permanently restored. This gleam, however, lasted but three years, when he was once more assailed by the most woful of human trials, which he bore with equanimity.

The productions of this original and ingenious composer are too numerous, and indeed too well known, to be particularized here: the choicest of them were, in 1824, collected and published in two handsome volumes, by his son-in-law, Mr. H. L. Craun. To a third he contributed, one of the compositions of the composer, engraved from a painting by his brother (henceforward Sir Augustus Callcott, R.A.), a remarkably strong likeness, in which the ingeniousness and felicity of his disposition, and the reach and quickness of his intellect, are very happily depicted.

Dr. Callcott left a widow, eight daughters, and two sons. One of the latter has already attained considerable distinction in his father's art.

(Horsey's Memoir of Dr. C.; and Harmonicon, i. 53.)

CALLCOTT, SIR AUGUSTUS WALL. This very distinguished landscape painter, frequently styled the English Claude, was born at Kensington in 1779, and died in the same house in the year 1840. He was the brother of the distinguished composer, Dr. Callcott, and he himself in early life officiated for several years in the choir of Westminster Abbey under Dr. Coke. He however preferred painting to music, and for some time pursued both studies. He had not quite gained the success he had hoped, when he was painted upon the tuition of Hoppner, in 1798, and which he exhibited, led him to the final choice of painting as his profession. Very little experience, however, showed him that of the most promising if in 1803 he devoted himself exclusively to the study of landscape painting. Richard Wilson had adopted a similar course, but notwithstanding his great ability, with very different success.

Callcott was elected an associate of the Royal Academy in 1807, and a member in 1810. He presented a beautiful painting called 'Morning;' in 1837 he was knighted by the Queen; and at the death of Mr. Seguer in 1844, he was appointed his successor as Conservator of the Royal pictures, an office which he held for a very short time, and of no great emolument, yet honourable, and sufficiently valuable to be of very great importance to the venerable painter, who was so enfeebled by long illness, that in the last few years of his life he was unable to undergo the ordinary exertions of his profession. He was buried on the 30th of November in Kensal Green Cemetery, where his wife, Lady Callcott, had been buried two years previously.

Lady Callcott was the widow of Captain Graham, R.N., and was married to Sir Augustus in 1827. She was born in 1788; married in 1804; and was the daughter of Captain Dundas, and was married early in life to Captain Graham, with whom she went to India in 1809. She remained in India two years, and visited during that period many of the most remarkable places in the country, and also listed an account of her travels after her return home. She published at a later period two works relating to India, where she dwelt for some time,—'Three Months in the Environs of Rome,' and 'Memoirs of Fussian.' In 1821 she embarked with her husband for South America, but Captain Graham died during the voyage, and was buried at Valparaiso.

After her second marriage she paid another visit to Italy, in the company of Sir Augustus, and turned her attention particularly to the history of art. In 1830 she published her last historical work, under the title—'Essays towards the History of Painting,' which, notwithstanding an unfortunate corruption of names, partly due to the old translation of Philyrion Holland, and a few other inaccuracies, is a very creditable performance, and considering that it is the only popular work on ancient painting that has hitherto appeared in English, it is a useful contribution to the library of the young student in art.

It is not intended, in this notice, to give a list of Callcott's pictures, nor even a view of his labours. He was for many years a steady and large contributor to the exhibitions of the Royal Academy. His landscapes were generally of small dimensions, and all very similar in style; but most of them are extensive as it is, and the best quiet, and strongly truthful as a class. He was less extensive in his distances than Claude, being more defined, and, certainly to the true lovers of nature, more pleasing; in his foro-grounds he was more correct and natural than Claude, except in the foliage, especially of large trees: in colour he was perfectly true and natural. His works are perhaps more frequently characteristic pictures of certain scenery, as 'Italy,' 'Morning,' 'Evening,' &c., than mere views of particular localities. Many of his pictures also have their titles from the occupancy; as 'Market,' and 'Waiting for the Passage-boat,' 'The Ferry,' &c.; he painted also some marine pieces. In 1833 he exhibited in the exhibition a beautiful picture called 'Harvest in the Highlands,' in which the figures were painted by E. Las, the son of the late Mr. R. A.

In 1837 he exhibited a picture from the possession of Mr. G. A. Cal, a remarkably strong likeness, in which the ingeniousness and felicity of his disposition, and the reach and quickness of his intellect, are very happily depicted.

Dr. Callcott left a widow, eight daughters, and two sons. One of the latter has already attained considerable distinction in his father's art.

(Art-Union Journal, 1843-1845; Catalogues of the Exhibitions of the Royal Academy; Wasing, Kunstdere und Künstler in England.)

CALLIMACHUS (Καλλιμάχος), a celebrated Greek sculptor of uncertain age, but probably of about the time of Phidias. He was apparently an Athenian, though some think him the son of Callimachus of Samos. He was the inventor of the Corinthian capital. Callimachus is, as the other hand, supposed to have been of Athens, from a report noticed by Vitruvius, and in part by Pliny, and Pausanias, but the Athenian is said to have been Callimachus and Callimachus, according to the emendation of Sillig, which agrees just, signifying one who weakens or effeminates an art, in relation to the excessive finish by which he greatly injured the effect and value of his works. Pliny calls him the culminating of himself, and says that he never knew when to leave off linking his works; the same fault was found with Protagoras.

If Callimachus invented the Corinthian capital, this circumstance enables us, as Winckelmann has observed, to see degree to fix his time. It must have been before the Olympic games in 400 B.C. for Sophocles an temple of Minerva, according to Pausanias, with columns of the Corinthian order at Tegae; and he cannot have been much earlier than that date, as his style was so elaborately and finished.

Dionysius of Halicarnassus and Calamis on the origins of Lyons, on account of their finian and neatness. Callimachus is also said to have used the drill in working marble, a fact attested by several modern critics, who suggest that he may have invented the drill in use, but cannot have been the first to use it in working marble, as it has evidently been used in the hair of some of the most antient statues, which, from the other evidence concerning Callimachus, must have been executed long before his time.

There is a bas-relief in the capitol at Rome, with καλλιμάχος engraved upon it, which represents a dance of three hecctas and a fawn; and some have supposed this to be the same work which Pliny notices as a dance of two girls by Callimachus. This perhaps signifies the inscription to be a forgery, or that there must have been some other Callimachus, who lived later than the subject of the notice. The characters of the inscription are, according to him, of the subjects of the work itself are too insignificant to have been singled out by Pliny or his authority as a production worthy of record. According to Pausanias Callimachus was not an artist of the highest merit. (Dio, 43. 12.; Vitruvius, ii., 4.; Pausanias, ii. 20.; Winckelmann, Werke, vol. v.; Sillig, Catalogue Artificum; Thiersch, Epochen der Bildenden Kunst, &c.)

CALLIPERS. (CALLIPERS, P. C.)

CALLISTRATUS, a Roman jurist, who was writing...
under the joint reign of Severus and Antoninus (1. tit. 19. e. 3; 49. tit. 14. s. 3), by whom are meant Septimius Severus and his son Caracalla. Some, however, believe that 1. Lampridius (Alexander Severus, 68), mentions a Callistratus as one of the Council of the Emperor Alexander Severus; and this may be the Callistratus who was writing under Severus and Antoninus.

Callistratus is one of the Jurists from whose writings Justinian's Digest was compiled [JUSTINIAN'S LEGISLATION, P. C.]: the works of Callistratus from which the excerpts in the Digest are taken were six books Do Cognitionibus; six books of the Edictum Monimentorum; four books of the Jus Fisci; three books of the Digesta, and one book of the Cognationes. It appears from Institutions being mentioned as one of the works of Callistratus, that he was one of those Roman Jurists who worked on institutional treatises, such as Gaius.

A genus of plants belonging to the natural order Callitrichaceae. The flowers are without calyx or corolla, with two bracts at their base; one stamen; two ovaries, each lobed and imperfectly 2-celled; the styles 5, subulate; the fruit dry, separating into 4 indehiscent carpels. Kützing has figured a decided calyx belonging to this genus. Five species have been described. Four of these are natives of Great Britain. They are water-plants with smooth leaves, and are known by the name of Water-starworts. C. berna is common in fresh water, snow-white flowers. C. platycarpa is found on mud or in shallow water; seldom, and then apparently by accident, in deep water. C. pedunculata is found in marshes; and Babington has described a variety, C. p. sessilis, which is found in lakes. C. subulata is found in streams, bordering watersides.

(Babington, Manual of British Botany.)

Callithrix. [Thuea, P. C.]

CALLUNA (from castlow, to make beautiful), a genus of plants belonging to the natural order Ericaceae. It has a 4-parted, menziesiform coloured calyx, longer than the 4-cleft, campanulate corolla, surrounded by four green bracts; 8 stamens, with dilated filaments; the capsule 4-celled, the dissections adhering to the axis; the valves opening at the three-fourths, white flowers, and a greenish-ochraceous fruit. This species of this genus, the common heath (C. vulgaris). It is a low-tufted shrub with small, sessile, closely imbricated, keeled leaves, arranged in four rows, each leaf having two small spars at the base, and nearly or quite smooth. The colour of the flowers varies from a deep red to white, and numerous varieties have been named. This plant is common on every heath in Great Britain. The varieties are ornamental when planted in the garden. They should be grown in a place exposed to the sun, may be propagated by layers or cuttings under a bell-glass.

(Babington, Manual of British Botany.)

Calligorgia, ANGELO, born at Fudio in 1599, of a family originally from Corfu, studied at Venice, and entered at the age of 28 into the Oard, a religious order founded by St. Basil, which belonged to the order of the Camaldulenses. After having taken his vows, he was sent to Ravenna to teach theology, and there finding a rich library at his disposal, and a well-informed and well-disposed librarian, he acquired a large store of varied literary knowledge. At Ravenna he made acquaintance with the learned Queirini, afterwards cardinal. Calligorgia, after some years, returned to his monastery of St. Michele, where he spent the greater part of his remaining life in his favourite literary studies. He was induced to compile an annual selection from the numerous papers which were read in the various scientific and philological academies scattered about Italy, and which, for want of a common journal, remained buried and forgotten. So they respectively are. Calligorgia undertook the task, in which he was assisted by Pia Caterino Zeno, Facciolati, Valliniari, Muratori, Manni, and other learned contemporaries. He began to publish in 1728; at Venice, the Raccolta d'Opuscoli Scientifici e Filologici, which continued to appear periodically till 1757, when the series closed by its fifty-first volume, which contains an index of the whole collection. He resumed it, however, in 1754, under the title of Nuova Raccolta d'Opuscoli Scientifici e Filologici, which he carried on to the time of his death, in 1774. The work was continued by his son, Antonio Mandelli till 1784, when the forty-first and last volume of this second series appeared. The two series constitute an ample store of Italian learning during the 18th century. Amidst the great number of learned men of that period in Italy there are many others who are truly valuable, and which could not be found anywhere else. Calligorgia wrote also a kind of literary journal entitled 'Memorie per servire alle Storie Letterarie'; he wrote with Apostol Zeno in the journal 'Storia Minerva', and he also contributed to a new edition of the 'Biblioteca Gallica' of Cinelli. Calligorgia was appointed in 1780 Revisor or book Censor for the Venetian State. He left a voluminous correspondence, which is inedited.

(Lombardi, Storia della letteratura italiana nel Setecentro.)

Calophyllum (from kalos, beautiful, and phiavlo, leaf), a genus of plants belonging to the natural order Guttiferae. It has a bracteate calyx consisting of 2-4 unequal calyces, usually 4-seriate sepals; 4 petals, purple, oblong, indefinite stamens, free or connected at the base, filaments short, anthers inserted by their base, 2-celled, bursting longitudinally; the style twisted, crowned by a large capitate stigmas; the fruit, a globose, globose or egg-shaped, 1-celled, 1-seeded; the seeds large; the fruits are tree, the leaves of which have numerous transverse parallel veins, which give them a very beautiful appearance.

C. Inophyllum has oblong or obovate obtuse leaves, usually emarginate, round branches, long acuminate flowers, racemes axillary, 1-flowered, usually opposite peduncles. This tree is a native of the East Indies, and often attains a height of 90 or 100 feet. It has large handsome leaves like those of a water-lily, an egg-shaped fruit, and a fruit about the size of a walnut. When the trunk is wounded, it exudes a yellow viscid juice, which frequently hardens to the consistence of a gum. It is a common plant in Malabar, where it yields fruit twice a year, in March and September, and frequently attains the age of three hundred years. The nuts afford a fixed oil, which is expressed, and used for burning in lamps, for making ointment, &c. This tree is cultivated in Java for the sake of its shade and the fragrance of its flowers. The bark and the exudation are used for medicinal purposes.

C. Caloche, Caloche tree has oblong or obovate, obtuse or emarginate leaves; hermaphrodite or male flowers; lateral, very short racemes. This plant is a tree 60 feet in height, and is a native of the Caribbean islands. It has white sweet-scented flowers, and a round or oblong berry, which contains a white solid kernel. An oil is expressed from the seed for domestic uses and for burning in lamps. The timber is used for various purposes, especially for staves and cask-headings. Lindley says 'that the true East Indian Tacamahaca is produced by Calophyllum Caloche.' There are however several gourds brought into the market under the name of Tacamahaca, of which formerly more was used than at the present day. The Tacamahaca seu Rosina Tacamahaca is one of the ornamental plants of the old Pharmacopoeias, and is used for producing the Elelphrium tomentosum and E. ecolomum, plants belonging to the natural order Amerylideae. It is described as a resin of a brown yellow colour, spotted with white, easily broken into pieces, which have a shining fracture, burning and having no medicinal virtues. It says that it was not employed in his day 'as an internal medicine, and as an external I cannot perceive its virtue.' It was used for making plasters as a counter-irritant, for which there are forms in the continental Pharmacopoeias at the present day. There is however another form of Tacamahaca brought to Europe, called Tacamahaca in herbs. It got this name from being collected in little ground-shells. This is the true East Indian Tacamahaca, which is collected from C. Inophyllum in the East India islands, and from C. Tacamahaca in Madagascar and the Mauritius.

(Bischoff, Medicinisch-pharmaceutische Botanik, Loullon, Encyclopedie; Don, Gard. Diet.; Lindley, Nat. Syst.)

Calotype. [Photography, P. C. S.]

Calvert, DENIS, sometimes called FLAMMINGO, a distinguished painter in his time, especially in landscape, was born at Antwerp about 1558. He settled early in Bologna, and studied under Fontana, and afterwards with Sabbatini, with whom he visited Rome and assisted in some works there. Sabbatini had more influence upon the style of Calvert than Fontana, who however taught him the value of perspective, in which he excelled. In 1584, Calvert visited some scenes in Parme. Calvert returned to Bologna and opened a school there, which became very celebrated and was numerous attended; he is said to have taught 437 painters. His school was unrivalled in Bologna until the establishment of the Carracci, with whom he was undoubtedly, through his painting, a pupil of the Carracci, who had a special interest in him.

Some of the greatest scholars however of the Carracci had been students in the school of Calvert, as
Domenichino, Guido, and Albani, three of the most famous of the Bolognese painters.

Calvert died at Bologna in 1619. He is spoken of with great respect by Malvasia and other Italian historians of art. There is nothing particularly Flemish in his style; his pictures, of which there are still several in Bologna, are generally well coloured, and strictly in an Italian style of design: in landscape he was superior to that of his Bolognese contemporaries.

His father, Mr. Thompson, was a St. Michael in the Church of San Petronio, and a Purgatory seel Graziu.

(Malvasia, Feuille Pittorie, Lanzi, Storia Pittorica, &c.)

CALYCEPHYLLEUM (from ελυξ, calyx, and φίλλος, leaf) is a genus of Mints belonging to the natural order Cinchona.

It has the limb of the calyx truncate or bluntly 5-toothed, one of the teeth expanded into a petaloid coloured membraneous leaf; the corolla campanulate or funnel-shaped with a 5-petalled limb; five anthers, the filament rising from the throat of the corolla; the anther oval, exerted; the style ending in 2 reflexed stigmas; the capsule dehiscing at the apex, oblong, 2-celled, many seeded; the seeds fixed to the linear placenta, imbricate, oblong, girded by a very narrow membranous wing. The species are small smooth trees, with opposite glabrous leaves, short stipules, and flowers disposed in axillary and terminal dichotomous corymb.

One of the most remarkable species of this genus has been lately described by Sir Robert Schomburgk as a native of British Guiana. There are several genera closely allied to Calycophyllum, as Mussandra Pinkeya, &c., in which one of the teeth expands into a petaloid and coloured leaf of a membraneous nature; but the species discovered in the Guiana the like expansion of the calyx, has a rose colour, and as the flowers are very numerous the whole tree assumes the colour of the rose. In describing the discovery of this plant, Sir Robert Schomburgk says, that the garden of nature in Guiana, clothed in tropical luxuriance; and among those productions of a congenial sun and fertile soil, figure to yourself trees from forty to fifty feet high presenting a mass of leaves the colour of our favourite flower, from a deep pink to the lightest rose; and perhaps your fancy will assist you to form some idea of the picture I beheld at one of the valleys of the river Rapununci, where a high mountain on the river's left bank turns its bed boldly to the east. The banks of the stream and the steep side of the hill were afevered with trees clothed with rose-coloured leaves; and only on a near approach could the shining green leaves and the spikes of flowers of a velvety blue be discovered.

This plant is called by its discoverer after Lord Stanley, theuke, Calycophyllum Stanlyanae. The beauty of the tree is very hard. It is very bitter to the taste, and, like the rest of the order, is probably febrifugal.

(Hooker: London Journal of Botany, 1644.)

C. alpina, the generic the Linnean's classification of Tribolites, for the species of Crustacea allied to the well known Dudley fossil Calymene Blumenbachii. (Tatlow, P. C.)

CALYSTEGIA (from καλυστής, calyx, and εγγύς, to cover) 1, a genus of plants composed of species formerly included under Convolvulus. It is distinguished by two large bracts which enclose the flower. It has 5-parted calyx, a campanulate 5-plicate corolla, one style, a 2-lobed stigma, globose or terete lobes, a 2-celled ovary with 2 ovules; the capsule only 1-celled from the shortness of the dissepiment.

The species are laticeous, glabrous, twining or prostrate herbs, with solitary 1-flowered peduncles.

C. sepium, Great Bindweed, has sagittate or cordate, very acute, acuminate, entire, cordate, keeled; acute bracts longer than the calyx, but one half shorter than the corolla; the peduncles square, sepal acute. This is the Convolvulus sepium of older botanists. The genus Calystegia is not respect by Malvasia, and is called Gemma Silicium. In the description of 20 or 30 grains it has been recommended as a hydropugous cathartic in dropsy, by Mason Good.

C. soldanella, Sea Bindweed, has trailing, glabrous, rather fresh green, ovate, or a little broader, angular, wings, angled large, ovate, blunt, mucronate, generally shorter than the calyx. It is a native of many parts of Europe on the sea-coast, and also some parts of Asia. The young stalks are sometimes eaten pickled. The juice of the mature plant is however a cathartic.

Several other species of this genus are described. Like the Convolvulus, they are elegant in growth, and most easy culture. They may be propagated by pieces of the root or by seeds. The C. Soldanella should now and then be watered with salt water.

(See Linnean's Dictionary)

CAMBIA/SO, LUCA, sometimes called LUCIETTO DA GENOVA, a very celebrated Italian painter in fresco and oil, was born at Monalea near Genoa, on St. Luke's day, in 1527. He was instructed by his father Giovanni, a painter of Genoa, and distinguished himself as an artist when a boy, and though he is not known to have visited Rome in his youth, his best works have many of the qualities of the great Roman masters. After a long and honorable residence in Genoa, where he did not receive a rival, he was, in 1583, to Spain, with his son Ondan and L. Cano, one of his pupils, to assist him in some works which Philip II. had commissioned him to execute in the Escorial. Cambiaso was invited to Spain by Philip II. to supply the place of his old friend and follower George de Gemme, who died in Madrid in 1579. Cambiaso and his brother executed several paintings together in Genoa.

Cambiaso executed several works in the Escorial, the largest of which was an immense fresco of Paradise, consisting of a vast number of figures, arranged as the monks stand on the ceiling of the choir of the church of St. Leocastro. He received 12,000 ducats for this picture, yet it occupied him only fifteen months; it was however in the opinion of many the best of his works in Genoa; the composition is formal and bad, but for this the monks must be held responsible. The oil painting of John the Baptist preaching in the Wilderness, also in the Escorial, is the best of his Spanish works. He died at the Escorial in 1584, and Philip greatly regretted his loss. He was called Cagio by the Spaniards. He was a painter of surprising facility and power; Armenini compared him with Tintoretto. He painted however latterly with great negligence, a stream of works which once promise to a disappointment is seen. The story is this: his wife died, and Cambiaso invited her sister to keep house for him and take care of his children; he however soon became desperately in love with her, so he could not marry her by the law of the Roman church, he set out for Rome to pray the Pope Gregory XIII. for dispensation. He took two pictures with him as presents for his holiness, which were accepted, but his prayer was disavowed, and he was ordered to remove the lady from his house;柬此, he could not marry her by the law of the Roman church, for dispensation is seen. He was called Cagio by the Spaniards. He was a painter of surprising facility and power; Armenini compared him with Tintoretto. He took two pictures with him as presents for his holiness, which were accepted, but his prayer was disavowed, and he was ordered to remove the lady from his house; \n
CAMBRIAN ROCKS. Professor Sedgwick has a long establishment in North Wales, beyond a doubt, the important fact, that beneath the strata and flags of Denbighshire, the Cambrian strata are almost entirely covered by deep sediments, the surface being broken by numerous small basins, which are filled up with a variety of rocks and clays. The Cambrian rocks are consequently very imperfectly known to the geologist. The geologists of North Wales are therefore enabled to present the subjoined view of the formations separately proposed by Sedgwick and Murchison, in connection with the terms used in this work:
campanella was sent Viceroy to Naples by Philip III., and a fresh tax on 'fuci (hearts), or families, was imposed. Dis-

satisfaction became loud all over the country. In August, 1699, a citadine of Catanaro revealed the plan of a conspiracy, in which Campanella, his brother, and natives of Nicestra, were leaders. It was said that their object was to proclaim a republic, and that they relied upon the Turks for assistance, and had carried on a correspondence with Ci-

casa Pasha, a Turkish emissary, but his plan was frustrated, and the leaders, who were then scouring the neighbouring sea with his squadron. Such a plan may have been conceived by some person, but that a man of so much information and judgment as Campanella, who had spent many days in his works, a monk, and an advocate for a universal Christian monarchy, could have concocted a republic in Calabria by means of 'Turkish assistance and against the power of the Spanish monarchy, is incredible, and the sequel tends to disprove the charge. The probability is, he was impeached of perjury and false accusation, and himself indignantly against the oppression of the viceregal government, and that his historical information supplied him with comparisons unfavourable to it. Campanella and Dionisio Fonzie were arrested, together with many more, and sent to Naples, where several of the conspirators, having confessed under torture, were executed. Campanella remained in a dungeon for years; he was put to the torture seven times, five times his trial was begun afresh, but he confessed nothing, and was never brought to trial. After some time his imprison-

ment was mitigated, and he was allowed to see his friends. Charges of heresy were mixed up with political charges against him; he was even accused of being the author of the book published on Tribus Imperii, wherein Campanella had been published thirty years before he was born. The Calabrian Giannone asserts that Campanella was really a leader of the Great conspiracy, which he says was concocted chiefly by monks; but Giannone, like most Neapolitan jurists, was pre-

dered against monks and churchmen in general, and be-

lieved the insinuations of the viceregal lawyers. He says that he had seen a copy of the proceedings against Campanella and his fellow-conspirators, but we know what the forms of the trial was, and the extent of the continuance; and the continuation to Giucicardini, has followed Giannone implicitly. A search has been lately made in the archives of Naples for the papers relative to Campanella's imprisonment and trial, but nothing has been found. Most of the documents existing of the viceregal judicial administration are of a later date than Campanella's trial; the previous records of the sixteenth and begin-

ning of the seventeenth century are missing. Antonio Serra, a Calabrian, and one of the earliest writers on political economy, was one of the individual judges who were tried before Campanella, and he also was tortured and kept in prison. [POLITICAL ECONOMY, P. C.] Campanella enjoyed at one time a glimpse of favour from the viceroy Duke of Osuna, who loved to converse with him on politics; but when this viceroy was succeeded, on the return of the Spanish, he tended to assume supreme power at Naples, Campanella became the object of fresh suspicions, and his captivity was made more rigorous. At last, in 1626, he was released from his prison at the pressing request of Pope Urban VII., but, probably in order to obtain his release, urged that as the prisoner had been charged with heresy and was moreover an ecclesiastic, he ought to appear before the tribunal of the Inquisition. Campanella was therefore sent to Rome, and lodged in the building of the Holy Ofce, where previously he was a prisoner at large, and was treated with considerate attention. After three years more, making in all thirty years of confinement, he was allowed his full freedom. He remained for several years under the favour of the court, and was also received at Rome, but his papers were seized on the road, and it seems that they found their way to the archives of the Inquisition at Rome; but the author remained un molested for the present. From Rome Campanella returned to his native country, where he liv'd for some time at Stilo, the selling of his books adorning him, and leading to his admission into the Confiscation of Italy, at the request of a senator of Venice, on the question, whether the foreign ambassadors at Venice should be allowed to arrange the Senate in their respective language. The Senate was not in any way interfered with, and Campanella returned to Padua, where he finished the writing of his universal treatise on the state of the world, which he called 'Vomero; and it is said that he was sent to the Spanish Inquisition, and that his book was burnt at Rome, that the text was destroyed, and that the Inquisition was not satisfied.
made them cry aloud against the protection granted by the pope to a turbulent friar, whom they compared to Luther. Campanella stood evidently in danger, even in the midst of Rome; so great was then the dread of the Spanish power in Italy, that the pope himself appeared to be deemed insufficient, and Nollius proposed to Campanella to take refuge in France, and he sent him off in his own carriage, disguised as one of his attendants, and with letters of recommendation to the minister Cardinal Richelieu. Campanella arrived safely at Mars- sen in March 1634; he sat at the learned Pwder, who treated him most kindly and provided him with necessi- ties for the remainder of his journey. At Paris he had a very favourable reception from Richelieu, who conversed with him for hours together, and introduced him to Louis XIII., who granted him a pension. Campanella, worn out by his sufferings, retired to the conven of his or- der, the afterwards famous Convent of the Jacobins in the Rue St. Honoré, where he died, in 1669.

The works of Campanella are very numerous. The Do- minican bibliographers Echard and Quetif, "Scriptor Ord. Prud.," give a long catalogue of his inedited works. Among those that have been published, the following are deserving of notice.—1. "Prediconum Philosophiae Insanum, seu de Natura Rerum, cum Praefatione ad Philosophos Germaniae," Frankfort, 1617. The preface is by Tobias Adami, a learned German, who became acquainted with Campanella in his con- fession at Rome. Campanella intrusted him with several of his works 2. "De Fato Sibi et De Sensu Nullius Dominum Mundum esse Del vivum statum beneque cognoscentem; omnes illius partes sensa donatas esse, quacumque ipsarum conservatio sufficit; et fere omnium naturae aque- ronum, "Frankfort, 1629. 3. ", another work, was composed, as well as several others, by Campanella during his Neapolitan captivity, and was published in Germany by Adami, but the author published a second edition of it at Paris in 1636, which he dedicated to Cardinal Richelieu. Father Mesenne wrote to refute the book as heretical, and Athanasius of Constantinople wrote against it his "Anti-Cam- panella," Paris, 1655. 3. "Realis Philosophiae Epilogistico Partes IV.," tobi Adami Annotationibus, accedit Ap- pareniis hominm eruditorum, Tito: Ch. Sola, seu Libri Philosophici," Frankfort, 1650. The "Civilis Sola's" has been often reprinted separately, and translated into various languages. 4. "Apologia pro Galileo, ubi discutitur urano radio philosophandu quam Galileus celebret favrat Scripturae sacris an adversatur," Frankfort, 1662. 5. "Astrologiae Rerum Libri VI.," Lyon, 1622. A second edition was published at Frankfort in 1630, with the addition of a seventh book, "De Fato Sideral viando." Campanella had faith in astrology; 6. "De Evagrypho, seu omnibus, cum comprobatur, non cognitum in Rome, 1631; and a second edition, with additions, Paris, 1636. 7. "De Predestinatione, Electione, Reproduction, exullius Divinae Gratiae, Cento Thomisticum," Paris, 1636. The author discusses some of the opinions of Thomas Aquinas, and defends Aristotle against the Irish and the English. 8. "Germanicam Metaphysicurn Rerum Libri XVIII.," Paris, 1638. 9. "Philosophiae Rationalis Partes Quinque," 10. "De Gentilismo Non Reditendo Quaestio unica," Paris, 1636. The ques- tion proposed is, whether it is lawful to contradict Aristotle. The following works of Campanella were published after the death of the author. 11. "De Libris propriis et recta Ratione Studendi," Paris, 1642, in which the author speaks of himself, his studies, and his works. It was edited by Nollius, who knew Campanella during his imprisonment in his "Considerations Politiques sur les Coupe d'Etats," 12. "De Monarchia Hispanica Discursus," Amsterdam, 1640. This, perhaps the most remarkable work of Campanella, was written after his confidential stay in Naples. It is an ab- solute sketch of the political world of that time, and with reference to the Spanish monarchy, which was then the preponderating power, it showed how that preponderance could be increased. The author has been com- pared to Machiavel, but there is no apparent difference between them, that although Campanella is not very scrupulous as to sincerity and faith in political transactions, yet he reproves cruelty and persecution, and prefers milder and more humane manners. In fact his age was different from Machiaveli's, and such barefaced atrocities as those of Borgia would not have been tolerated. In many respects the advice which Cam- panella gives to the King of Spain, especially concerning the in-ternal administration, is very sound. This work made great noise at the time; it was reprinted several times, and was translated into English, and published during Cromwell's

Protectorate : "A Discourse touching the Spanish Monarchy, wherein we have a political glass representing each partic- ular country, province, kingdom, and empire of the world, with ways of government by which they are kept in obedience, written by Thomas Campanella, a Spaniard, in the learned Pwder of Paris, for attaining the Universal Monarchy of the World, prima- rily concerning England, Scotland, and Ireland, how to rise division between King and Parliament, to alter the govern- ment, and form a Commonwealth. And introduction to Holland and other seafaring countries, &c., with a preface by William Prynne of Lincoln's Inn." The following same will serve to give some idea of the tenor of the work, which was written towards the end of Elizabeth's reign—by opinion is that the King of Spain should do well to retire under hand some certain merchants of Florence that are sly and subtle persons, and that traffick at Antwerp, who (be- cause they are not so much hated by the English as the Spaniards) are treated with some such of the English as are some- way or other descended from some of the former kings at England, and should promise each of them severally (so of them knowing anything of what is said to the other) in the possible aid that can be from Spain, for the resisting the adventurers plot, and the change of the King's person to King James of Scotland, and promise him that he will assist him to the utmost of his power in his getting possession of the kingdom of England, upon this condition, that he will neither send in the English as conquerors, nor as aforesaid, but that he shall not annoy or any way disturb the Spanish from the West Indies. Again, on the other side, let the Eng- landers under labour with the English peers, and other chief of the Parliament, and egge them on to moderate their own people, and to abandon from the kingdom of England, either in the form of a republic, or else make it into a king- dom of itself, throwing off all obedience to England, with promising aids to each of them in particular, and that so much the rather, because in that kingdom or island the Catholics, and especially the friars that are in the order of St. Francis, are very greatly esteemed and beloved. There is also not greater agreement and correspondence between the Spanish and the Irish than betwixt them and the English, whither to be, might be very advantageous to them, and which is also the reason of the elime, and the nearness of these two countries one to the other. There are also in Ireland many voluntary persons, and such as have fled their countries, being men that are most impatient of government, and yet are good people, and the philosophy of this kind, as it hath been shown already. But this sort of men is not very rare to be found, either in England or Scotland also. (Special Monarchy, chap. 25.)
CAMPANULA (diminutive of Campana, on account of the bell-shaped flowers) is the common name of a genus of plants belonging to the Campanulaceae order. C. pulchella, the campanula, is an elegant plant with flowers in a terminal raceme. C. rapunculus, the radish plant, is a member of this genus.

C. canina, the foxglove, is a species of C. pulchella. Its flowers are blue or white, and it is often cultivated for its ornamental value.

C. nemoralis, the meadow saxifrage, is a species of C. pulchella that is found in Europe. Its flowers are white and are often used in gardens.

C. grandiflora, the great bellflower, is a species of C. pulchella that is found in Europe. Its flowers are large and white, and it is often cultivated for its ornamental value.

C. impatiens, the touch-me-not, is a species of C. pulchella that is found in Europe. Its flowers are purple or pink, and it is often used as a garden plant.

C. acaulis, the small bellflower, is a species of C. pulchella that is found in Europe. Its flowers are small and white, and it is often used in gardens.

C. palustris, the marsh bellflower, is a species of C. pulchella that is found in Europe. Its flowers are white and are often used in gardens.

C. matricaria, the matricaria, is a species of C. pulchella that is found in Europe. Its flowers are blue and are often used in gardens.

C. muralis, the wallflower, is a species of C. pulchella that is found in Europe. Its flowers are orange or red, and it is often used as a garden plant.

C. nana, the dwarf bellflower, is a species of C. pulchella that is found in Europe. Its flowers are small and white, and it is often used in gardens.

CAMP, THOMAS, was born July 27, 1777, at Glasgow, where his father, who was the youngest son of a Highland laird, Campbell of Kerness, and had then attained the age of sixty, had spent his life as a merchant, but was now out of business. Thomas was the youngest of a family of ten sons and daughters. At the university of his native city, where he was educated, he appears to have divided his time between the usual exercises and many of which his general industry and proficency. It is related that a translation (into verse, we suppose) of the Clouds of Aristophanes, for which he obtained a prize in the Greek class, was pronounced by the professor, the late learned and eccentric Professor Young, to be the best exercise ever given in any student of the university. Others of his performances of this date were, several poetical translations from Sophocles, Tyrtaeus, and other Greek writers, some of which are still preserved, and which, if the university papers, and had been for a short space resident in Edinburgh, when he published there, in April, 1799, his Pleasures of Hope, which brought him at once to notice. Few first poems indeed have ever made so great a sensation; and it has come to pass that a great number of the world, who, perhaps, never saw Campbell before, or had been conversant with the most popular with readers will not rest principally upon this juvenile work. It is, to be sure, in subject, form, and extent, the work of greatest pretension that he has left us. Yet, with all its imposing declamatory splendour, and the true poet's glow that animates it, it betrays, both in execution and in substance, the raw and unskilful mind of youth, and it will probably not be the production on which its author's more enduring fame will stand. It was a poem of extraordinary promise however for a first production; of which almost before any other young writer has shown in our more recent literature. Certainly at least it could not be considered as a mere clever imitation of any reigning model or other previous poetry; taken all in all, in its faults as well as its beauties, its manner and spirit were its own. It is said that the profits he derived from the sale of the Pleasures of Hope enabled Campbell to visit the Continent, which he did in the latter part of the year 1800. He saw part of Germany, and having proceeded along the rest of the Rhine, he reached the safe distance of the battle of Hohenlinden, fought in December of that year. He was stopped in attempting to pass into Italy, and returned to England by the way of Hamburg. A severe cold, he says, destroyed his health, and obliged him to return to Edinburgh; with other poems, among which were his noble verses on the battle of Hohenlinden; his spirited and stirring song, Ye Mariners of England, written at Hamburg on the prospect of war with Denmark, his Exile of Erin, also written there; and his Lochiel's Warning, which had been written at Edinburgh since his return. After being nearly two years in Edinburgh, he came to London in 1803; and having in the autumn of that year married his cousin, Miss Matilda Sinclair, he appears to have continued in earnest the pursuit of literature as a profession. Among the works which he produced in the course of the next five or six years, was a compilation, published anonymously at Edinburgh in 1807, in three volumes, 8vo., entitled Annals of Great Britain, from the Accession of George III. to the Peace of Amiens. He also contributed several articles to the Edinburgh Encyclopaedia, begun in 1808, under the superintendence of Dr. (now Sir David) Brewster. Meanwhile, in 1806, he had received from the Marquis of Hartfort penance for 2000. a-year, which he enjoyed while he lived. With the exception of a few occasional short pieces, he published no more poetry till his Gertrude of Wyoming appeared in 1814, accompanied in the first edition by Lord Ullin's Daughter' and his Battle, though it is perhaps the finest lyric; and in a subsequent edition by his beautiful and passionate tale of 'O'Connor's Child.' Gertrude of

Wyoming 'is written upon the whole in a much purer style than the Pleasures of Hope'-though still not without occasional forms of expression having more sound than sense, such for example as the transport and security entwine which耳 have explored the recesses of the British poets,' in seven volumes, 8vo. (reprinted in 1841, in one volume, 8vo., with additional notes by Mr. P. Cunningham). The 'Essay on English Poetry' by which this work is introduced is written in many passages with great beauty and classic correctness. The year after its publication the author delivered a course of lectures on English Poetry, at the Surrey Institution, where Hazlitt had lectured on the same subject two years before. In 1830 also Campbell undertook the editorship of the New Monthly Magazine, which he retained till 1833. In 1824 he published his 'Theodric, a domestic tale:' it wants the force and fire of some of his other poetry, but it is perhaps the sweetest of all his poems. He never wrote anything in a more poetical and touching manner than in the close of this poem. For some years after this he was much occupied by the interest he took in the emancipation of Greece and of Poland, and also in the project of the London University, now University College (which he contributed largely to), to which Campbell was a very devoted friend. Campbell had in originating the idea of a university in London, the execution of the work is due to others. [University College, P.C.] In 1827 he was elected Rector of the University of Glasgow, taking up his residence in the city in the two following years. He lost his wife, by whom he had one son, who survives him, in 1830; in 1831 he established the Metropolitan Magazine upon relinquishing or losing the editorship of the New Monthly, but retained its management as a member of the firm of Longman, Hurst, Rees, Orme, and Brown. In 1832 he paid a visit to Algiers, an account of which he published in the Metropolitan Magazine in a series of papers, afterwards, in 1837, collected and reprinted in two volumes, 8vo., under the title of 'Letters from the South.' The other publications of his last years, none of which brought him much reputation, were a 'Life of Mrs. Siddons,' 2 vols. 8vo. 1834; a 'Life of Petrarch,' 2 vols. 8vo. 1841; 'Life and Times of Frederick the Great' (of this he professed to be charmed), 1839; and one of his most interesting works, 'Pilgrim of Glencoe,' a poem, 8vo. 1842. In the summer of 1843 he retired to Boulougne; and he died there on the 16th of June, 1844. His body was brought over to England, and interred on the 2d of July in Westminster Abbey, near the centre of Poet's Corner, close to the tomb of Addison.

(Gentlemen's Magazine for August, 1844; Chambers' Cyclopaedia of English Literature, vol. ii. pp. 369, 370; and Campbell's various Works.)

CAMP, the name of a celebrated family of painters of Cremona. The eldest and master of the others was Giulio Campi; the others were Antonio, Vincenzo, and Bernarino Campi; the first three were the sons of Galleano Campi, who died in 1536, the last apparently their cousin. Antonio and Vincenzo were both living in 1591, in which year the latter died. Antonio was painter and architect.

Giulio, according to Lanzi, was the Ludovico, and Bernarino the Annihale, comparing them with the Carracci as a school. Giulio was born about 1500, and died in 1572. He was the scholar of Giulio Romano at Mantua, and contributed greatly to the dissemination of the principles of the Roman School throughout Lombardy. As to the rest of those as those of all the Campi, are very numerous. In many instances he has combined the vigour of design of Giulio Romano with the colour of Titian, but his works are in various styles.

Bernardino Campi was born in 1522, and died about 1590. Though instructed by Giulio, he adopted a different style from his cousin, and is generally allowed to have surpassed him. They were both very similar in colour, in design and composition, but they were more different than they appear.
